PREFACE.

THE DICTIONARY of SCIENCE, LITERATURE, and ART was designed to supply a want which could not be met by the larger Encyclopædias of modern times. Works of so vast an extent as the *Encyclopædia Britannica* or the *Encyclopédie Française* are too expensive for general circulation, while from their size they cannot well serve as manuals. . On the other hand, Special Dictionaries, though they may exhaust some one branch of learning, are not intended to supply information on others; and thus a work like the present, possessing the comprehensive character of a general Encyclopædia without its amplitude, and affording in a convenient form an abstract of the principles of every branch of Science and an explanation of the various terms ordinarily met with in Literature and Art, still appeared to be wanting. The first edition of the present work was, therefore, offered to the public as a compendious Dictionary of a convenient size, adapted to the wants and means of all classes, and furnishing within comparatively narrow limits precise and accurate information on the all but infinite variety of subjects which it embraces. Great pains were taken to make the definitions clear, correct, and concise, and to insure a method of treatment which, though brief and compendious, should be neither flimsy nor superficial. No statement was made on doubtful matters without pointing out the source from which it had been derived; while the references given to the best works on all subjects of importance enabled the reader to extend his enquiries at will.

The first edition of this Dictionary was published twenty-four years ago. The period which has since elapsed has been marked by great progress in almost every department of human knowledge. The limits and relations of the Physical Sciences have been more

accurately determined, and the area of research in each has been greatly extended and more carefully scrutinised. The discovery of new objects has led to the invention of new names, and the accumulation of facts has in many cases modified or exploded theories which had gained general acceptance. Experience has justified the claims of Political Economy to the rank of a science; while the examination of the laws of evidence has strengthened, if it may not be rather regarded as having called into existence, the science of Historical Criticism. The analysis of Language has produced results of the utmost importance, not merely affecting the classification of dialects, but throwing light on many stages in the earliest developement and history of the human mind, and on many subjects of the highest interest connected with the legends and poems, the laws and society of pre-historic ages. With such changes as these, it was obviously impossible that any dictionary compiled more than twenty years ago could meet the wants or adequately represent the knowledge of the present day, while any attempt to remedy the defect by mere corrections and supplements would probably render the book even less satisfactory to the general than to the scientific reader. To the latter the additional information given in a new edition might be technically useful, while his professional experience would have made him acquainted with the progress of knowledge in his own department. The more general reader would need to be informed not merely of new facts, but of the degree in which these facts have modified the character or tendency of each particular science. In a dictionary designed to give a clear but strictly succinct account of the principles of all sciences in a way which should be acceptable both to general readers and special students, this requirement could not be met except at the cost of re-editing and re-writing the work throughout. Thus re-written, the present edition is offered to the public as substantially a new work. As in previous editions, the several departments under which the subjects are arranged have been intrusted to writers who have devoted themselves to the special topics respectively assigned to them. The Editors believe, therefore, that the work may be consulted with confidence by all who wish to make themselves acquainted with the principles of each particular science, with the details and history of many, and with the main facts of the many subjects with which it

is necessary at the present day for all intelligent persons to have some acquaintance. In each case the first object of the writers has been to affirm positively none but duly ascertained facts, to leave open all doubtful questions, and to reject statements for which a more stringent research has failed to produce adequate evidence, even though these statements may have for many the force and charm of old associations.

A few words will suffice to indicate the changes which have been made, on these principles, in the present edition.

In the Biological Sciences, the rapid progress of Comparative Anatomy since 1842, especially in its morphological aspects, has rendered necessary the introduction of a large number of new words; and it is hoped that all such words in current use will be found in this portion of the Dictionary. On the other hand, many words have been excluded which, although occasionally employed, lack that stamp of authority which alone can justify their insertion in a standard dictionary. In Zoology, the recent discoveries of interesting generic forms of life have been described in new articles; whilst the improvements which have taken place in classification have led to a careful revision of the systematic arrangement employed in the last edition. But only those classifications have been accepted which are in general use, in preference to others (possibly more accurate, but at present more hypothetical) which may be adopted at some future time. In Palæontology, a large number of new articles have been required to describe the more important fossil forms with which the progress of the science has made us acquainted.

In Geology, it has been thought that the purposes of the Dictionary would be better answered by presenting the subject under the several branches into which the science is divided. While, therefore, the general article in this department has been greatly curtailed, this loss of matter is more than compensated by new articles, to which the reader is carefully referred in the general article, and which, it is hoped, will put him in possession of all the conclusions which in the judgment of the best geologists may be considered trustworthy on the important subjects which have of late years furnished matter for geological discussion, especially on questions relating to changes of the earth's surface and climate, and to the antiquity of the human race.

The introduction of Physical Geography is practically a new feature in the present edition. Although an attempt to impart to this work the character of a Geographical Dictionary would obviously be out of place, it was felt that an important branch of knowledge would not be fairly represented without giving some account of the principal features of the globe, its oceans, marine currents, and continents, its mountain chains, lakes, and inland seas, and the general action of volcanic forces.

In Astronomy, the application of photography to the production of permanent records of celestial phenomena, the improvements in astronomical instruments, and the wonderful discoveries made through spectrum analysis, have all been concisely but carefully described; and an attempt has been made to render this Dictionary a useful companion to the Telescope, by recording especially the results of recent observations.

In Chemistry and Physics, also, a thorough revision of articles had become necessary; and the new matter added contains, it is hoped, a notice of all the most important advances even in sciences of such vast extent. In Mineralogy, large additions have been made to the number of terms, although it is not pretended that an exhaustive list has been given of technical names, many of which would rarely, if ever, be met with except by strictly scientific readers.

The great progress made during the last generation in the oldest of all sciences, Mathematics, has rendered a slight alteration of arrangement advisable. The expositions of the more permanent portions, which are fully treated in standard text-books, have been curtailed in the present edition; while an attempt has been made, for the first time, to collect and render intelligible the many terms which have been introduced into modern Geometry and Algebra, so far as the limits of this work would permit. More advanced readers will find copious references to the best sources of information in each branch of the science.

The recent applications of science to Agriculture have been carefully treated in the articles relating to this subject; while the systems of Botanical classification have been examined by the light which the growth of the science has thrown on their correctness or inaccuracy.

The general subject of Architecture has been kept distinct from

the special details of Building and Engineering. Under the latter, the inventions and improvements of the present century have, it is hoped, been fully described. Under the former, mere theories and conjectures have been excluded from what is designed to serve as a philosophical account of the developement of all styles of Architecture.

The Military and Naval articles have been subjected to a strict revision. These articles in the last edition were, and indeed could not fail to be, behind the standard of the present day. Great pains have been bestowed to correct all mistakes which may have been made through inadvertence or want of knowledge, as well as to give the latest information on all Military and Naval subjects of general interest. With this view, all words have been inserted which are likely to be met with by any except advanced professional students of the art. The changes effected by the introduction of iron armour-plates and rifled arms have been fully described, and the most important points connected with the effects of shot from rifled guns are noticed under the head of PROJECTILE.

For the articles in Political Economy which appeared in former editions, we are indebted to Mr. M'Culloch, whose ability and merits are gratefully acknowledged. But it cannot be doubted that, if his life had been spared, he would have felt it necessary to modify many statements on subjects which of late years have undergone a more thorough discussion. On this account, as well as in order to give the results of recent experience, all the articles belonging to the science have been thoroughly revised, and in great part re-written, while many new articles have been added on subjects connected with labour and capital, and other topics which of late years have assumed more or less importance.

The Theological articles are strictly confined to a statement of facts and doctrines, or of arguments in support of or against the latter, as urged by either side, without any controversial remarks on the subjects to which they relate.

In the Historical articles many changes have been rendered necessary by the increasing attention paid to the laws of evidence, and to the critical tests which distinguish oral tradition from authentic contemporary narratives. These tests have been, it is hoped, impartially applied in all those articles which treat of periods for which no really historical evidence exists, and of which many must be set

aside as belonging to that region of Mythology on which the progress of Philological Science has recently thrown great light. Indeed, the science of Comparative Mythology may almost be said to have come into existence since the first edition of this work was published. As a necessary consequence, almost every article on matters connected with Mythology, Epic Poetry, and the legends of what are known as the Heroic Ages, has been wholly re-written, while new subjects have been introduced so far as they were needed in order to give an adequate account of the present state of the science.

On the subject of Derivations or Etymology, the Editors wish to leave no room for misunderstanding. Their first object has been to give the nearest form in which any word occurs in cognate languages to which it is most closely related. Hence in cases where the English term is, letter for letter, the same with a foreign word, all that has been done is to name the language in which that word is found. But it is not meant that the mention of a word in a parallel language, such as Dutch, Swedish, or German, implies the borrowing of the word from the one to the other, or even that where a word is found in English, Latin, Greek, and Sanscrit, any ground is furnished for the conclusion that the English has received the word from the ancient languages, or that any one of the latter borrowed it from the rest. The task of tracing words to their original source is one of which it is perhaps impossible to exaggerate the importance; but it belongs wholly to the professed philologist, and can be at best but briefly treated in the present work under the head of LANGUAGE. Hence, with but very few exceptions, no attempt has been made to give the history of the changes of words. The English *age* is referred to the French *âge*; but it is not the province of a general Dictionary like the present to trace the word back through the Old French *édage*, and the Latin *ætaticum*, *ætās*, *ævitas*, *ævum*, to the Greek *αἰών*. In such instances, however, references have been given to philological works, by the aid of which the reader may if he wishes carry his researches further. Nor must it be assumed that words given in derivations are in all or in most cases words used in what are called the best classical periods. Terms of doubtful origin are marked as such, any further explanation being withheld unless a derivation may be proposed with some plausibility. Not unfrequently a derivation is given from the works of recent philologists, whose names are appended. Such derivations

are given on the responsibility of the author, and not necessarily as being considered in themselves satisfactory or conclusive. It appeared only fair, however, that in doubtful cases such writers should at least be allowed a hearing. In the case of scientific terms, whose hybrid character in many instances is admitted on all hands, nothing more has been attempted than to give the words out of which (sometimes contrary to all rule or analogy) they have been coined or compounded.

In the number of scientific terms explained in this work, a very large increase will be found in the present as compared with the last edition. It would indeed have been impossible within the limits of this Dictionary to include all the terms employed in any branch of science; but it is believed that a sufficient number has been introduced to meet the requirements of all general readers and non-professional students. The increase of matter which this greater fullness of treatment has entailed, together with the adoption of a more legible type, has made it necessary to extend the size of the work to three volumes.

Lastly, the Editors express their hope, that no omissions may be found of any matter of real importance contained in the last edition, and that in general accuracy and fullness of information the present work may adequately exhibit the results of the scientific research and general knowledge of the present day.

LIST OF CONTRIBUTORS.

GENERAL EDITOR	{ W. T. BRANDE, D.C.L. F.R.S.L. & E. of Her Majesty's Mint, Hon. Prof. of Chemistry in the Royal Institution of Great Britain.
ASSISTANT EDITOR.	{ The Rev. GEORGE W. COX, M.A. late Scholar of Trin. Coll. Oxford.
Agriculture	{ JOHN CHALMERS MORTON, Editor of the 'Agricultural Gazette,' &c.
Architecture and General Literature	{ The Rev. GEORGE W. COX, M.A.
Astronomy, Observational and Descriptive, and Meteorology	{ E. FRANKLAND, Ph.D. F.R.S. Professor of Chemistry in the Royal Institution of Great Britain; and J. N. LOCKYER, Esq.
Biological Sciences, comprising Anatomy, Physiology, Zoology, and Paleontology	Prof. RICHARD OWEN, F.R.S. LL.D. D.C.L. Superintendent of the Nat. Hist. Departments, British Museum; and C. CARTER BLAKE, F.G.S. For. Assoc. of the Anthropolog. Soc. of Paris.
Botany and Gardening	{ JOHN LINDLEY, M.D. F.R.S. F.L.S. Emeritus Prof. of Botany in Univ. Coll. London; and THOMAS MOORE, F.L.S. Curator of the Botanic Garden, Chelsea.
Building and Engineering	{ G. R. BURNELL, Architect and Civil Engineer, F.R.I.B.A. F.G.S. F.S.A.
General Chemistry and Physics	{ W. T. BRANDE, D.C.L. F.R.S.L. & E.; E. FRANKLAND, Ph.D. F.R.S.; and JOHN ATTFIELD, Ph.D. F.C.S. Director of the Laboratories of the Pharmaceutical Soc. of Great Britain.
Geology, Physical Geography, and Hydrology	{ D. T. ANSTED, M.A. F.R.S. F.G.S. &c. Hon. Fell. of King's Coll. London.
Law and General Literature	{ HERMAN MERIVALE, M.A. C.B. late Fell. of Balliol Coll. Oxford.
Mathematics, Pure and Applied	T. A. HIRST, Ph.D. F.R.S.
Military Subjects	{ Lieut. HENRY BRACKENBURY, R.A. F.S.A. Assistant-Instructor in Artillery, Royal Military Academy, Woolwich.
Mineralogy	{ HENRY WILLIAM BRISTOW, F.R.S. F.G.S. Hon. Fell. of King's Coll. London; of the Geolog. Survey of Great Britain.
Music	Prof. W. POLE, F.R.S. Mus. Bacc. Oxon.
Naval Subjects	DENHAM ROBINSON.
Navigation	H. W. JEANS, F.R.A.S. Royal Naval Coll. Portsmouth.
Painting and the Fine Arts	{ RALPH N. WORNUM, Keeper and Secretary of the National Gallery.
Political Economy	{ JAMES E. THOROLD ROGERS, M.A. Prof. Polit. Econ. Oxford; Tooke Prof. of Economic Science and Statistics in King's Coll. London.
Printing, Bibliography, &c.	{ R. J. COURTNEY, Superintendent at Messrs. Spottiswoode & Co.'s Printing Office.
Theology and Ecclesiastical Literature	{ C. MERIVALE, B.D. Chaplain to the Speaker of the House of Commons.

DICTIONARY

OF

SCIENCE, LITERATURE, AND ART.

A

A. The first letter of the Alphabet, in all known languages, with the exception of the Amharic, the modern dialect of Abyssinia, in which it is the thirteenth, and of the Runic, in which it is the tenth. It was called *Alpha* by the Greeks, and *A'eph* by the Hebrews.

A, in Heraldry, is the dexter chief or chief point in an escutcheon.

A had an arithmetical value amongst the Greeks and Romans: its value with the former was 1, and with the latter 500, or with a line over it 5000.

A, in Logic, is the sign employed to denote a universal affirmative proposition. [Logic.]

A, *a*, or *aa*, in Medical prescriptions, is used for *ana*, *in equal parts*.

A. The name of one of the notes in music, corresponding to the French *La*.

A.A.A. in old Chemistry, means an amalgam.

Aardvark (Dut. *earth-hog*). The *Oryzctopus capensis*, an insectivorous animal remarkable for the facility with which it burrows in the earth. It is more closely related to the armadillos than to the ant-eaters.

Abaca. The *Musa textilis*, a kind of plantain growing abundantly in the Philippine Islands. Of the fibres of this tree a cordage is made which has the property, like that of coir, of floating in water. The sea water does not rot it, and it therefore requires no tarring. A portion of the fibre, which is white and fine, is manufactured into excellent linen and other valuable textures.

Abacinare (Ital. *to dazzle*). A punishment of the middle ages, in which the criminal was blinded by holding red-hot irons before his eyes.

Abaciscus. In Architecture, any flat member. The square compartment of a mosaic pavement. [Abacus.]

Aback. In sea language, denotes the position of the sails when laid flat against the mast by the force of the wind. This may happen either by a sudden change of the wind, or an alteration

ABACUS

of the ship's course; or the sails may be *laid aback* for the purpose of avoiding some imminent danger.

Abacot. A cap of state worn by the old English kings. It was made in the shape of a double crown.

Abacus (Lat.). In Architecture, the upper, or top, moulding of the capital of a column, so called from its supposed resemblance to a table (*ἀβάξ*). It serves to form a wide bed for the architrave of the entablature immediately above it.

ABACUS. An ancient instrument used for facilitating numerical calculations. The name is of doubtful origin. The instrument consists essentially of a parallelogram divided by parallel bars, on which small pebbles or counters are placed. The counters on the lowest bar denote units, those on the second tens, those on the third hundreds, and so on; one counter on a superior bar being equal to ten on the bar immediately below it. By means of nine counters for each bar, it is obvious that any number may be thus expressed. It will be observed that the artificial value given to the counters, according to the positions which they occupy, is entirely analogous to our numerical system of digits. The form of the instrument admitted of considerable variety. The Grecian abacus was an oblong frame, having wires stretched across it, strung with perforated beads or little ivory balls. In the Roman abacus the counters were slid along grooves. The Chinese, like the Greeks, employ wires with beads; and with them the abacus or Swan-pan is in universal use, as it conveniently adapts itself to their decimal divisions of weights and measures. The abacus continued to be used in European countries during the middle ages. Instead of a board, however, with bars or wires, it became the practice to cover a bench or *bank* with chequered cloth, on which the counters were disposed. Hence our terms *exchequer*, *bankrupt*, &c. For an excellent account of the abacus, and of palpable arithmetic generally, see the

article on arithmetic, in the *Encyclopædia Britannica*.

Abaft, or Aft. In sea language, denotes nearness to the stern or hinder part of the vessel. Thus a thing is abaft the foremast when it is between the foremast and the stern.

Abaisseé (Fr. *abaïsser*, to lap down). In Heraldry, a term applied to the wings of eagles, when closed, or with the tips looking down to the point of the shield.

Abandonment. A term used in marine insurances, where, before compensation can be demanded, the insurer must abandon his interest in any portion of the rescued property. It is also used, in the language of the customs, to signify the abandonment of an article by the importer to avoid payment of the duty.

Abatement, Plea of. In Law, is pleaded to a declaration, writ, &c., on account of some defect in form. [PLEADING.]

ABATMENT. In Heraldry, symbols of disgrace introduced into arms: mentioned for the most part only by English heraldic writers. A *delf*, or *quadrant spot*, is the sign of a revoked challenge: an *escutcheon reversed* belongs to an ungentleman person or deserter: a *point dexter parted*, to a boaster: a *point in point*, to a coward: a *point champain*, to one who kills a prisoner of war: a *gore sinister*, to effeminate persons: a *gusset sinister* denotes voluptuousness, a *gusset sinister* intoxication. The only abatement now used in practice is the *baston*, which belongs to bastards; it is in the form of the bend sinister, contains one-fourth of the dimensions of the escutcheon, but does not reach quite to its circumference.

Abater, or Abator. In Law, one who puts an end to a nuisance, or who enters a house or land vacant by the death of the former possessor, and not yet taken possession of by his heir or devisee.

Abatis (Fr.). A term of military engineering applied to a species of fence placed in front of a breastwork or on a glacis, for the purpose of impeding the advance of an attacking party. Generally speaking, an abatis is composed of trees cut down, and laid with their branches pointing towards the enemy, so as to offer resistance to the troops attempting to scale the works, by rendering it necessary to use both hands to clear a way through the boughs, whilst the defenders are at full liberty to use their weapons.

Abaton (Gr. *inaccessibile*). An edifice at Rhodes, built by Artemisia to commemorate her conquest of the island. It afterwards received the name of Abaton, because the Rhodians, on regaining their liberty, made it inaccessible.—*Vitruvius*, ii. 8.

Abattoir (Fr. from *abattre*, to knock down). A large public slaughter-house, under the direct control and management of the municipality of a town, for the express purpose of insuring the killing and preparation of animal food under the conditions most favourable for the health of the population consuming it. The abattoirs of Paris, commenced under Napoleon I. in

1810, and finished by the Bourbons in 1818, are even at the present day the best models of this class of municipal constructions. A full description of them is to be found in La Bruyère's *Études sur l'Art des Constructions*; Grantham's *Description of the Abattoirs of Paris*; and in one of the detached essays of the Architectural Society, published in 1849.

Abb, or Abb-wool. Names given by clothiers to the yarn of a weaver's warp.

Abbassides. The name of a family of Arab caliphs, who reigned from 749 to 1257. The name is derived from Abbas ben Abd-al-Motalleb, a paternal uncle of the prophet Mohammed. The most celebrated of the Abbassides was the wealthy, luxurious, and splendid caliph Haroun al Raschid, whose reign is regarded by Mohammedans as the golden age of their dominion.

Abbes (Fr. *abbesse*). The governess or superior of a monastery or abbey for females. By a decree of the Council of Trent she must be of the age of forty years, and have professed eight years at least.

Abbey (Fr. *abbaye*). In Architecture, the conventual buildings of a monastery, including the church. In Ecclesiastical History, an abbey is a monastery governed by an abbot, under whom is a prior. The abbeyes had the highest rank among religious houses, and enjoyed some superior privileges.

Abbot (Heb. *abba*, father). The superior of a monastery for men. Monastic societies, being originally composed of laymen, were obliged to have recourse to the assistance of a neighbouring priest to administer the sacraments and perform other clerical functions among them. Afterwards the superior of the society in many cases entered into orders, and exercised the ministerial office for the convenience of his community, under the title of abbot. From the beginning of the sixth century this practice became universal, the abbot having absolute power within his own monastery, but being himself subject to the authority of his diocesan. This subjection, however, the abbots gradually threw off to a great extent, and in many places themselves assumed the titles and authority of bishops. Such were the mitred abbots, and the crosiered abbots; the former of whom, to the number of twenty-six, sat in the English parliament with the bishops and two priors in the reign of Henry VIII.

Abbots are properly superior in rank to priors; the latter being often appointed by the abbot to superintend a dependent foundation. But the distinction does not appear to have been regularly observed, and there are certain orders whose superiors are always called priors; as the monks of Vallombrosa, the Cistercians, Bernardists, Feuillants, Trappists, Grandmontanists, and Premonstratenses. After the sixteenth century, besides the regular 'abbots,' there grew up in France a class styled 'abbots commendatory,' who were candidates for some priory or abbey in the gift of the crown, and

ABBOT OF MISRULE

under engagements (not often fulfilled) to enter into orders within a year. They wore the 'petit collet' as the symbol of their devotion to the church; and of this class were the 'abbés,' so well known in literary and fashionable life.

Abbot of Misrule. In ancient times, was the master of the revels, called in Scotland the 'Master of Unreason.'

Abbreviatio Placitorum (Lat.). In Legal History, an abstract of ancient pleadings made prior to the year-books.

Abbreviation (Lat. *brevis, short*). In Arithmetic. The process by which a fraction is reduced to lower terms; thus the division of the numerator and denominator of $\frac{16}{14}$ by 2 reduces or abbreviates the fraction to $\frac{8}{7}$.

ABBREVIATION. In Music, a stroke which, placed over or under a note, divides it into quavers if there be only one; if two, into semi-quavers; if three, into demisemiquavers.

ABBREVIATION. In Writing, before the invention of printing, a variety of abbreviations were used, most of which have gradually fallen into disuse: they generally consisted in substituting the initials for the words. Of the abbreviations at present in use, the following are those which most commonly occur.

In Titles:—

A.B. or B.A., Bachelor of Arts	K.C.B., Knight Commander of the Bath
A.M. or M.A., Master of Arts	K.C.I.L., Knight Commander of Hanover
S.C.L., Student in Civil Law	K.G., Knight of the Garter
B.C.L., Bachelor of Civil Law	L.J.D., Doctor of Laws
D.C.L., Doctor of Civil Law	M.P., Member of Parliament
B.D., Bachelor of Divinity	M.R.I.A., Member of the Royal Irish Academy
D.D., Doctor of Divinity	Mus.D., Doctor of Music
Clk., Clerk or Clergyman	Ph.D., Doctor of Philosophy
M.D., Doctor of Medicine	Q.C., Queen's Counsel
F.R.S., Fellow of the Royal Society	R.A., Royal Academy
C.B., Companion of the Bath	R.A., Royal Artillery
G.C.B., Grand Cross of the Bath	R.E., Royal Engineers
G.C.H., Grand Cross of Hanover	R.M., Royal Marines
K.B., Knight of the Bath	R.N., Royal Navy
	S.T.P., Sanctæ Theologiæ Professor
	W.S., Writer to the Signet

Miscellaneous, Diplomatical, &c.:—

A.D., the year of our Lord	A.C. or B.C., the year before Christ
A.H., the year of the Hegira	A.U.C., the year from the building of Rome
A.M., the year of the world i.e., that is to say	Nem. con., no one contradicting
ib., in the same place	Nem. dis., no one dissenting
id., the same	M.S., manuscript
N.B., for nota bene, observe viz., for videlicet, to wit	A.M., morning
L.S., (in a deed) the place of the seal	P.M., afternoon
R.S. and L.S., right and left side	H.M.S., Her Majesty's ship or service
N.S., new style (since 1752)	D.G., by the grace of God
O.S., old style (before 1752, and in the Greek calendar)	F.D., Defender of the Faith
	H.R.E., Holy Roman Empire
	U.S., United States of America

Abbreviators (Lat. *abbreviator, from abbrevio, I shorten*). Officers of the papal court who assist the chancellor in drawing up briefs

ABDUCTION

and petitions with a view to their conversion into bulls.

Abdication (Lat. *abdication, from abdicō, I abdicate*). In Politics, the renunciation of an office or dignity by its holder; but it is commonly meant to express the voluntary renunciation of supreme power. The most famous examples of this on record are the abdication of the dictatorship by Sylla, 76 B.C.; of the imperial throne, by Diocletian, A.D. 305; of the emperor Charles V., in 1556; and of Christina, queen of Sweden, in 1654. The Convention Parliament of 1688 used the word abdication to express the act of James II. in abandoning the government and kingdom. The word 'desertion' was rejected, as implying the possibility of a return. The Scottish Convention of Estates declared that James had 'forfeited' the kingdom. Abdication is said to differ from resignation, the former being unconditional, the latter done in favour of some other person.

Abditorium (Low Latin). In Archaeology, a secret place for hiding or concealing valuables.

Abdomen (Lat.). The great cavity of the animal body, which is liable to temporary changes in its dimensions, independently of respiration. In Entomology it forms, in insects the third, in arachnids the second, in both classes the most posterior, of the sections into which the body is externally divided, and contains the principal digestive and respiratory, and the whole of the generative organs. The enlargement of the abdomen, in relation to the activity of the generative functions, is most remarkable in insects; in some of which, as the white ant, or termite, it constitutes, at the full development of the ova, an immense proportion of the entire body of the female. In vertebrata the abdomen is not divided externally from the thorax; and only in one class, the mammalia, by an internal partition, or diaphragm. In vertebrata the abdomen is beneath the neural axis, and always on the ventral side of the body, from which the limbs are developed. In articulates it is above the neural axis, which occupies the ventral or under side of the animal.

The abdomen is the first-formed cavity in the development of the animal body, and is the most constant in its existence throughout the animal series. [CRANIUM and THORAX.]

Abdominals. An order of Malacopterygious fishes, including those which have the ventral fins situated under the abdomen, behind the pectorals. [MALACOPTERY.]

Abduction (Lat. *abductio, from abduco, I lead away*). In Law, the forcible carrying away of a woman, for the purpose of marriage or defilement. Where the female has property, or is presumptively entitled to it, such abduction is felony: and in all cases the taking of a girl under sixteen from under the protection of her parents is a misdemeanour. The crime of abduction, according to Sir Walter Scott (see his Notes and Introduction to *Rob Roy*) was at one period extremely common on the border of the Scottish Highlands.

ABDUCTION

ABDUCTION. In Logic, a form of argument, answering to the Greek *ἀπαγωγή*, wherein the greater extreme is obviously contained in the middle, but the middle not so evidently in the less extreme as not to require some further proof to make it appear.

Abductor. Abductor muscles are those which pull back or separate the limbs to which they are affixed.

Abelian Equation. The eminent mathematician Abel having shown that the solution of an irreducible algebraic equation [IRREDUCIBLE EQUATION], one of whose roots is expressible as a rational function of a second, can always be effected by the solution of a second equation of lower degree, modern algebraists sometimes distinguish equations possessing the property in question by the term *Abelian*.

Abelian Integrals. A term applied to a certain class of ultra-elliptic integrals, whose properties were first investigated by Abel. The term *Abelian function* is usually restricted to inverse Abelian integrals, which are analogous to functions of the amplitude of an ordinary elliptic integral, as also to inverse circular and logarithmic functions, such as, $\sin^{-1}x$, $\log^{-1}x$, &c. For further particulars the reader is referred to the memoirs of Abel, Jacobi, Richelot, Weierstrass, and others in *Crelle's Journal*.

Abellites, or Abellians. In Ecclesiastical History, a sect mentioned by St. Augustine, in Africa. They are said to have enjoined marriage and virginity, after the pretended example of Abel.

Abelmoschus (Arab. Kabb-el-misk, *musk-seed*). A tropical genus of the Mallow family, one species of which, *A. moschatus*, otherwise *Hibiscus Abelmoschus*, produces seeds which have a strong musky odour, and have been used in perfumery, and also medicinally. Another species, *A. esculentus*, is the ocho or gobbo of the West Indies, where its pods, on account of their nutritive mucilaginous qualities, are much used in thickening soups.

Aber. A Celtic term, implying the mouth of a river; as Aberdeen, the mouth of the Dee; Aberystwith, the mouth of the Ystwith, &c.

Aberdevine, or European Siskin (*Carduelis spinus* Cuv.). A small green and yellow finch, belonging to the same subgenus as the goldfinch of this country.

Aberrant. In Botany, where certain species or groups differ materially from their types.

Aberration (Lat. aberratio). A term used in Astronomy, to denote a change in the apparent positions of the celestial bodies arising from the combined effects of the motion of light and the motion of the earth in its orbit.

To explain the cause of this remarkable phenomenon, conceive a ray of light to proceed from a star S to an observer at O. If the station of the observer were at rest, or if the motion of light were instantaneous, the star would be seen in its true place at S. But neither of these circumstances can take place;

ABERRATION

the observer is carried rapidly forward by the motion of the earth in its orbit, and light occupies a certain time in coming from any of the heavenly bodies to the earth. Suppose, then, that while a wave of light advances from D to O, the observer has been carried forward by the earth's orbital motion from A to O. At O the wave will strike the eye with a velocity proportional to DO, and the eye will impinge against the wave with a velocity proportional to AO.

The two simultaneous impressions which the eye at O thus receives may obviously be represented in magnitude and direction by the lines DO and BO, equal to AO, and the effect is the same as if the eye had received a single impression from a wave of light advancing along the diagonal CO of the parallelogram BODC. The apparent place of the star therefore will be at S', in advance of its true place at S.

The angle COO, or the *aberration*, is obviously zero when the directions OB, OS, coincide, and it acquires its greatest value when these directions are perpendicular to each other. In the latter case it is called the *constant of aberration*, and expressed in circular measure (this angle being small) by the ratio

$$\frac{\text{velocity of the earth}}{\text{velocity of light}}$$

From Bradley's observation the Constant of Aberration was determined by Bessel (*Fundamenta Astronomiæ*) to be $20''.25$. Dr. Brinkley found it = $20''.37$. Mr. Richardson, from a series of 2,000 observations made with the two mural circles in the Greenwich Observatory, found the value of this important element = $20''.307$. (*Memoirs Royal Ast. Soc.* vol. iv.)

The effect of aberration on a star situated in the plane of the ecliptic is an apparent annual oscillation in a straight line extending to $20''.3$ on each side of its true position. A star situated in the pole of the ecliptic appears, from the same cause, to describe a circle around its true position as centre, and having a radius of $20''.3$. In any other position the apparent path of a fixed star is an ellipse whose major axis is $40''.6$ and minor axis $40''.6$, multiplied by the sine of the star's latitude.

The apparent places of the planets are also affected by aberration; but in this case, as the body from which the light emanates is also in motion, we must consider that the ray of light which enters the eye, and to which the correction for aberration must be applied, has proceeded, not from the place which the planet occupies at the instant of the observation, but from that which it occupied at as long an interval previously as light requires to traverse the distance between the planet and the earth.

The aberration was discovered, and its physical cause first explained, by Dr. Bradley. It is the most direct proof which astronomy furnishes of the motion of the earth round the

ABETTOR

ABERRATION. In Optics, denotes the deviation of the rays of light from the true focus of a curved lens or speculum; in consequence of which they do not unite in a single point, but are spread over on a small surface, and form a somewhat confused image of the object. This arises from two causes: 1st, the figures of the lenses or specula; and 2ndly, from a difference in the physical nature of the rays of light.

The surfaces of the lenses or mirrors of optical instruments are generally worked into a spherical form, on account of the difficulty of accurately obtaining the parabolic curvature which theory shows to be necessary to collect parallel rays into a single point or focus. Hence the rays meet the axis of the lens or mirror at different points, the amount of deviation depending on the magnitude and curvature of the lens. This is called the *Aberration of Sphericity*. The second cause of aberration, which occurs only in lenses, arises from the different degrees of refraction which the rays composing a beam of light undergo in passing from one medium into another. On account of this difference of refrangibility, the rays of light are separated, and the colours of the spectrum appear. It was long believed, and even by Newton himself, that it was impossible to refract without decomposing light; and hence the attempts that have been made to perfect reflecting telescopes, and adapt them to the purposes of accurate observation. But it has since been discovered that the refractive and dispersive powers of different transparent substances are in different proportions, and that the decomposition of the light may be prevented by combining substances of different refractive powers, for example, crown and flint glass, in the same lens. [ACHROMATISM.]

Abettor (Sax. *abedan*, to incite). In Law, an instigator or inciter; a person who promotes or procures the commission of an offence or felony, by his advice or encouragement. If an abettor, or, as he is then termed, an aider and abettor, be present at the commission of the crime, he is treated as a principal; if absent, he becomes an *accessory* before the fact. But in almost all cases of felony the abettor is considered as much a principal as the actual felon, especially in the case of murder, and the abettors of offences punishable summarily by justices of the peace are subject to the same penalties as the principals.

Abeysance (Nor. Fr. *beyer*, to expect). In Law, the fee simple, or inheritance of lands, is said to be in abeyance, when there is no person in esse in whom it can vest and abide. Thus, in a grant to A for life, and afterwards to the heirs of B, the inheritance remains in abeyance until the death of B, as there can be no heir to a living person. This theory, however, is now generally exploded. (2 *Bl. Comm.* by Sweet, 107.) A peerage descending to co-heiresses is said to be in abeyance.

Abib (Heb. *a green ear*). The first month of the Hebrew year, more generally known by

ABLUTION

the Chaldean name of *Nisan*. It is first mentioned in Exodus xiii. 4.

Abichite. A name for native arseniate of copper, after Prof. H. Abich. [CLINOCLASIS.]

Abies (Lat. *a fir tree*). The name of all those fir trees which, like the Spruce, the Larch, and the Cedar of Lebanon, have their leaves growing singly upon the stem, and the scales of the cones round and thin. The wood called by timber-merchants 'white deal' is produced by *Abies excelsa*; and a resinous or terebinthaceous substance by others: as Canadian balsam by *A. balsamea*; Strasburgh turpentine by *A. pectinata*, the silver fir; Venetian turpentine by *A. Larix*, the larch. Besides these, the substance called extract of spruce is furnished partly by *A. canadensis*, and partly by *A. nigra*. All the species are hardy, and, with the exception of larches, are evergreen, and in cultivation in this country. The most valuable for the timber are, *A. Douglasii*, *A. excelsa*, and *A. Larix*; the most ornamental are, *A. Cedrus*, the Cedar of Lebanon, *A. Deodara*, and *A. Larix*; the most worthless in Great Britain are, *A. canadensis*, *A. picra*, *A. balsamea*, and *A. pectinata*: the three latter form, however, fine trees in favourable situations. The wood of the fir is in very extensive use, and it is, perhaps, the most serviceable of all trees.

Abletineæ. A division in the natural order of Coniferous plants, comprehending the true firs and pines, and the araucaria-like pines, all which have cones with many rows of scales in which the seeds are formed.

Abletine. A resin contained in crude turpentine.

Abjuration, Oath of (Lat. *abjuratio*). Introduced by stat. 13 W. III., and regulated by 6 G. III. An oath asserting the title of the present royal family to the crown of England, and abjuring allegiance to that of the Pretender. A single oath is substituted for this and the oath of allegiance and supremacy by 21 & 22 Vict. c. 48.

ABJURATION of the Realm. In Law, signifies a sworn banishment; or the taking of an oath to renounce and depart from the realm for ever.

ABJURATION also signifies a solemn recantation of opinion: as, the abjuration of heresy required by the Romish Church. Henry IV. abjured Protestantism at Saint-Denis in 1593. Galileo was compelled to abjure his philosophical opinions by the Inquisition at Rome, in 1633.

Ablactation (Lat. *ablactatio*, from *ablacto*, I wean). A method of ingrafting trees. When the new stock is ingrafted with the old one and then cut away, it is *weaned* from the tree.

Ablative Case. The name given to the sixth case of Latin nouns, its chief use being instrumental. [GRAMMAR.]

Ablution (Lat. *ablutio*, washing). A religious ceremony, consisting in bathing the body, or part of it. It constituted a part of the Mosaic ceremonial, and was afterwards practised among the Jews, both by the priests and people. Ablutions are most rigidly enforced by the Mohammedans.

ABNORMAL

Abnormal (Lat. *ab, from*, and *norma, a rule*). Anything without, or contrary to, system or rule. Thus Horace calls a self-taught person—

abnormis sapiens, crassaque Minerva.

In Botany, if a flower has five petals, the rule is that it should have the same number of stamens, or some regular multiple of that number; if it has either four or six stamens, then, in such a case, the flower would be abnormal.

Abolitionists. In Politics, a name usually applied to the partisans of the abolition of slavery in the United States. It came into common use after the foundation of the 'American Anti-Slavery Society' by Garrison and others at Boston, in 1852.

Abomasus. The fourth stomach of ruminants, in which the process of digestion is completed.

Aborigines. The first, or original (*ab origine*), inhabitants of a country, that is, those who occupied it at the period when it began to be known, and who either were indigenous to the soil or had immigrated thither before the dawn of history. Some of the ancients supposed they had always inhabited the same soil, and were created from it, as the Athenians, who thence called themselves *autochthones*, i.e. sprung from the land. But the Romans and modern nations use the word Aborigines to designate those inhabitants of a country of whose origin nothing certain is known. Thus the Indians of America are properly called aborigines, because they were found there at its discovery, and we have no accounts of their having immigrated from any other quarter. (Sir G. C. Lewis, *On the Credibility of Early Roman History*, ch. viii. sect. 2; Ihne, *Researches into the Roman Constitution*, p. 39.)

Abortion (Lat. *abortio, miscarriage*). This term is usually applied to the morbid or unnatural expulsion of the fœtus in the human subject after the sixth week, and before the sixth month, of pregnancy. Before the sixth week it is called a *miscarriage*, and after the sixth month, *premature labour*. The 24 & 25 Vict. c. 100 deals with the crime of procuring miscarriage.

ABORTION. In Botany, the suppression, or absence, or non-development of an organ, the existence of which is either assumed by analogy, or detected by accidental conditions of the same plants.

Abortive. In Botany, is said of parts in plants that do not acquire their usual state of perfection. A flower only partially formed, a stamen whose filament has no anther, a seed which contains no embryo, or which consists only of skin, are cases of abortion. The term is also applied to parts which, although perfect in the beginning, cease to grow, and so end in being imperfect; thus ovules, which are not impregnated, and which shrivel up instead of growing into seed, are called abortive.

Abouhannes. An African bird, supposed to be the Ibis of the ancients.

Abracadabra. A celebrated term of incan-

ABRIDGEMENT

tation: especially used as a spell against fevers. The manner in which it was written and carried for that purpose may be seen in Defoe's *History of the Plague*. The word seems to be connected with *Abrasax* or *Abrahas*, a name inscribed on certain stones or amulets, together with the figure of a human body with the head of a cat and feet of a reptile. Various explanations have been attempted of the object of these curiosities: some from cabalistic and Egyptian derivations. Bellermin (Berlin, 1817) and Neander have written on the subject of the *Abrasax* stones.

Abramis (*Abramis* Cuv.). The name of a subgenus of Malacopterygious or soft-finned abdominal fishes, characterised by the absence of spines and barbels; by the dorsal fin being short and placed behind the ventrals, and the anal fin being long. The common bream is a species of this genus.

Abranchians (*Abranchia* Cuv.; Gr. α , priv., *Bpdyxia*, gills). An order (the third in Cuvier's arrangement) of Anellidans, so called because the species composing it have no external organs of respiration; they are divided into the setigerous abbranchians, or worms (*Anellida teretricola*), and the non-setigerous abbranchians, or leeches (*A. suctoria*).

Abrasion (Lat. *abrado, I rub off*). In Numismatology, implies the waste of coins, or their loss by wear and tear. This forms a considerable item in the expense of a metallic currency; and various means have been employed to lessen it, by alloying the coins so as to render them harder, by raising the borders so as to lessen the surface exposed to be rubbed, &c.

Abrasax. A genus of Lepidopterous insects, of the family *Geometridæ*; founded by Dr. Leach for the common magpie moth (*Abraxas grossulariata*) and other allied species. It is the larvæ of the *A. grossulariata* which commit the well-known ravages upon the gooseberry trees of our gardens, consuming the leaves almost as soon as they appear. They feed early in the morning, before the dew is off or the sun has much power: and it is at this time that they should be sought for and removed.

ABRAXAS, or ABRASAX. In Ecclesiastical History, a mystical term for the supreme God. The word in Greek letters represents 365, the number of the deities supposed by the Basilidians to be dependent under the All-ruling One.

Abraxite (Gr. α , neg., and *Bpdyx*, *I bubble*; because it does not effervesce before the blowpipe). A Mineralogical synonym for Gismondine.

Abridgement (Fr. *abrégé, to shorten*). In Literature, a compendious arrangement of the matter contained in a larger work. Before the invention of printing, when manuscripts were valuable, and the labour of writing them great, the abridgement of considerable works was an important branch of authorship. Among the best known abridgements of antiquity are the *History of Justin*, an abridgement

ABROGATION

of the lost *History of Trogius Pompeius*, the *Natural History of Solinus*, chiefly abridged from that of *Pliny*, &c. Few modern abridgements, taking the term in its strict sense, merit peculiar notice, or have been compiled with any other view than that of assisting education. This, however, is not the case with some works, called abridgements, which are intended to exhibit a summary view of some science or department of literature. The *Abrégé Chronologique de l'Histoire de France*, by the president Henault, is a work of this kind. Its success led to the publication of other abridgements of the same kind, of which the *Abrégé Chronologique de l'Histoire de l'Allemagne*, by Pfeffel, is probably the best.

ABRIDGEMENT. In Law, a declaration or count made shorter by subtracting or severing some of the substance therefrom; e.g. a man is said to abridge his plaint in assize, and a woman her demand in action of dower, where any land is put into the plaint or demand which is not in the tenure of the defendant. (Wharton's *Law Lex.*)

Abrogation (Lat. *abrogatio*). The annulment of a law by competent authority. A phrase derived from the practice of the Roman popular assemblies, in which the several tribes, *curiæ*, &c., were said *rogare suffragia*, to demand the *suffrage*: whence also the modern word *prerogative*. [COMITIA.]

Abrotanum (Gr. *ἀβρότανον*). An old name of the bitter aromatic southernwood, *Artemisia Abrotanum* of botanists. It is Abrotonum in Latin.

Abrupt (Lat. *abrupto*, *I break off*). A term in Botany, applied to anything which suddenly comes to an end. A leaf which is suddenly terminated without tapering to a point, a stem which is suddenly bent, a pinnated leaf without a terminal leaflet, are all abrupt.

ABRUPT. In Ichthyology, is applied to the lateral line when divided into two or more parts not contiguous.

ABRUS (Gr. *ἀβρός*, *delicate*, or *elegant*). A West Indian tree with papilionaceous flowers, and pods containing bright red seeds with a broad black scar on one side of them. The seeds are often strung into necklaces for children.

Abscess (Lat. *abscedo*, *I depart*). Inflammation in the membranous or fleshy parts of the body, attended by the formation of *pus*, and the consequent separation or distension of the parts affected; thus the integuments separate from the parts beneath, and form a tumour.

ABSCISS, or ABSCISSA (Lat. *abscindo*, *I cut off*). A term used in Geometry to denote a segment cut off from a straight line by an ordinate to a curve. [CO-ORDINATES.]

Absentee. In Politics, a word which has received a peculiar signification, denoting a landed proprietor who habitually resides at a distance from the district in which his property is situated. It is especially applied to Irish landlords and clergy. In 1716 a tax was imposed on absentees from Ireland, in all

ABSOLUTION

cases where their residence within it was for less than six months in the year; power of dispensation being secured to the crown. But it ceased to be levied in 1763, and has not since been renewed. Whether the absence of a landed proprietor be injurious to a country, in an economical sense, is a question which has been much debated of late years. The contrary opinion has been strongly advocated by Mr. McCulloch before the committees of the Lords and Commons on the state of Ireland, 1826 and 1830, and in *Essays*, &c. 2nd ed. 1859: see also *Quarterly Review*, vol. xxxiii., and Mr. Senior's *Outline of Political Economy*, *Encyclopædia Metropolitana*.

Absinthine (Gr. *ἀψίνθιον*). A peculiar bitter principle extracted from wormwood, *Artemisia Absinthium*.

Absinthium. The common bitter wormwood, called *Artemisia Absinthium* by botanists.

Absis, Apsis, or Apse (Gr. *ἀψίς*, *an arch*). In Ecclesiastical Architecture, a term used to express the end of the choir of a church, whether its form in plan be that of a semicircle, of a polygon, or even of a rectangle. Properly speaking, the word should be applied only to the vaulted extremity of the ancient basilicas; but by extension it is made to express not only the end of the choir of a church, but also the series of small lateral chapels usually arranged behind the altar end. In the early Christian churches, the bishop's throne was placed in the apsis behind the altar, and upon the axis of the church; but in later periods, the throne was placed at the end of the rectangular part of the choir, while the chapel of the Virgin was placed upon the continuation of the centre line of the apsis. Generally speaking, the crypts, or vaults, were placed under the apsis, so as to insure their being under the altar; and for this reason the apsis was at first constructively, and subsequently traditionally, raised above the level of the floor of the rest of the edifice. In the early Christian churches the apsis, separated from the choir by an open railing, was exclusively reserved for the officiating priests; but in mediæval churches, this special distinction is not retained, whilst the choir itself is separated from the nave by the rood screen or *jubbé*. Occasionally the ends of the transepts also are finished with vaults, and are said to have apsidal ends.

The apsidal form, as representing the round church in which the sacred mysteries were at first celebrated, has been retained throughout in the churches of France and Germany. In Italy it has been employed chiefly in baptisteries: in England it is reproduced in the circular chapter-houses, while the square end has been generally substituted in churches. (Fergusson, *Handbook of Architecture*, p. 619.)

Absolute Curvature. [CURVATURE.]

Absolution (Lat. *absolutio*). In Theology, a declaration of forgiveness of sin. The nature of sacerdotal absolution in the Church of Rome is defined in the Canons of the Council

of Trent. The Church of England has three forms of absolution: (1) in the Daily Service, which is merely declaratory; (2) in the Office of Communion; (3) in the Visitation of the Sick. (Hook, *Church Dictionary*.)

Absorbed (Lat. *absorbeo*, *I suck up*). In Painting, sucked up, imbibed. A term applied by the French connoisseurs to a picture in which the oil has sunk into the canvas or ground whereon it is painted, leaving the colour flat, and the touches indistinct. Our picture-dealers use the term *chilled* to express the same thing.

Absorbent Ground. In Painting, a ground prepared for a picture, either on board or canvas, chiefly with distemper or water-colour mixture, by which expedient the oil is immediately taken or sucked in, and a brilliancy imparted to the colours.

Absorbents. In Medicine, substances which remove acid at the stomach, such as magnesia and chalk.

Absorbing Well. A shaft, or well, sunk through an impermeable upper stratum to a permeable lower one, capable of carrying away the liquids thrown into it at a higher level than the permanent water line of the lower stratum. The dead wells, as they are called at Southampton, and in the south of England, are absorbing wells in gravel formations with close steined work at the top, and dry steining in the lower parts, and without paved floors, through which the liquids may infiltrate the surrounding ground. In France, the establishment of absorbing wells is regarded with great jealousy, and it is necessary to obtain the consent of the municipal authorities before commencing any such work: there is no legislation on the subject in England.

Absorption. In Physiology, is one of the vital organic functions, the object of which is primarily to convey to the circulating organs the due supply of the materials for the growth and support of the system; and, secondarily, to remove and carry from the same organs the decayed and useless parts of the body. [LACTEALS AND ASSIMILATION.]

Abstinence (Lat. *abstineo*, *I abstain*). In the Roman Catholic church, the refraining from the use of certain kinds of food on particular days, but only from the prohibited kinds. In this respect it differs from fasting.

Abstract. In Architecture, or in Engineering, the term 'abstract' is usually employed as a substantive, to express that portion of the bill of quantities, estimate, or account, which contains the summary of the various detailed articles; and it is upon this abstract that the prices are applied. In works upon Aesthetics, the term is used, both substantively and adjectively, to express the general and universal conditions affecting the subject under consideration, without reference to the adventitious circumstances by which it may be surrounded, or to the nature or influence of the details upon its external expression.

Abstract Mathematics, or Pure Ma-

thematics. That branch of science which treats of the relations or properties of magnitudes or quantities, considered generally, and without restriction to any individual magnitude. Thus, the proposition that the three angles of a triangle are together equal to two right angles, is an abstract truth, applying equally to all triangles whatsoever. *Abstract Mathematics* is opposed to *Mixed Mathematics*, wherein abstract properties or relations are applied to sensible objects. [MATHEMATICS.]

Abstract, or Pure Numbers. Numbers considered in themselves, and without reference to the particular things enumerated. The operations of common arithmetic are performed on abstract numbers.

Abstraction (Lat. *abstractio*, from *abstraho*, *I draw off*). In Metaphysics and Logic, the faculty by which, in contemplating any object, we can attend exclusively to some circumstances or qualities belonging to it, and withhold our attention from the rest. It is by the means of this faculty that we generalise, and arrive at the common terms or predicables [PREDICABLES] which belong to a number of objects. Thus, in considering a horse, by abstracting mentally the qualities which belong to that particular animal, we arrive at the notion of a quadruped, thence at that of an animal, &c. &c.; which notions constitute, in logical language, the successive genera and species of the individual horse.

Absurdum, or Reductio ad Absurdum. A term used in Geometry to denote a mode of demonstration in which the truth of a proposition is established, not by a direct proof, but by proving that the contrary is *absurd*, or impossible. There are many examples of this mode of demonstration in the Elements of Euclid.

Abundant Number. In Arithmetic, is a number such that the sum of its divisors is greater than the number itself. Thus, 12 is an abundant number, because its divisors being 1, 2, 3, 4, and 6, their sum, which is 16, is greater than 12. An abundant number is opposed to a *deficient* number, of which the sum of the divisors is less than the number itself; and to a *perfect* number, of which the sum of the divisors is equal to itself.

Abutment (according to some, from the Fr. *abouter*, *to abut*). In Architecture, the term *abutment* signifies the solid part of the structure against which the ultimate dynamical effort of an arch is exerted: of late years, however, it has been more especially applied to the resisting point of a series of arches, whilst the term *springing* has been more particularly applied to the abutment of single arches. In long bridges, viaducts, and aqueducts, the abutments are usually understood to mean the solid structures at the respective ends; the springings of the so-called 'land arches.'

Abys (Gr. *ἄβυσσος*). In Heraldry, denotes the centre of an escutcheon.

Acacia (Gr. *ἀκασία*). A genus of spiny leguminous trees, with pinnated leaves, and

ACADEMICS

small flowers collected in balls or spikes of a white, red, or yellow colour. They are all inhabitants of the warmer parts of the world; some of them, as *A. vera*, *A. arabica*, &c., yield gum arabic; others gum senegal: the bark of *A. Catechu* furnishes the astringent substance called catechu or terra japonica. The flowers of *A. Farnesiana* are exceedingly fragrant, and form one of the principal ingredients in Italian perfumery. The bark of many species abounds in tanning principles. New Holland and some other countries produce multitudes of species in which true leaves are not formed, but in their stead the branches are furnished with broad dilated petioles looking like leaves; these are called phyllodes.

Academics. A name given to a series of philosophers, who taught in the Athenian Academy, the scene of Plato's discourses. They are commonly divided into three sects, which go under the names of the Old, the Middle, and the New Academy. 1. The Old Academy, of which Plato was the immediate founder, was represented successively by Speusippus, Xenocrates, and Polemo. These philosophers, as far as the scanty notices remaining of them allow us to form a judgment, seem to have confined themselves to the task of elucidating and defending the doctrines of their great master. [PLATONISM.] A list of their works is given by Diogenes Laertius, b. iv. To them succeeded Arcesilaus, the founder of (2) the Middle Academy. Under his hands, the Platonic method assumes an almost exclusively polemical character. Whatever may have been his belief regarding the positive part of Plato's doctrines, he confined himself in public to the support of the negative portion; that, namely, which relates to the uncertainty of the impressions on the senses, and, consequently, of the judgments founded on them. His main object was to refute the Stoics, who maintained a doctrine of perception identical with that promulgated by Dr. Reid in the last century. [PERCEPTION.] Socrates is said to have professed, that all he knew was, that he knew nothing. Arcesilaus denied that he knew even this. Wisdom he made to consist in absolute suspension of assent; virtue, in the probable estimate of consequences; in the latter doctrine combating the ethical dogmatism of the Stoics, as in the former the intellectual. He was succeeded by Lacydes, Telecles and Evander, and Hegesinus. 3. The New Academy claims Carneades as its founder. It is not easy to define the limits between this and the Middle Academy. Like Arcesilaus, Carneades appears to have taken up a negative position. His system is a species of mitigated scepticism. He considers probability to be the sole legitimate object, alike in speculation and in practice. The doctrines of this school were adopted by Cicero, more, probably, in consequence of the advantage which, as an orator, he would derive from the practice of discussing both sides of a question, than from any solid conviction. Carneades was succeeded by his disciple, Clito-

ACADEMY

machus. Charmides, the third and last of the New Academicians, appears to have been little more than a teacher of rhetoric: an accusation, indeed, to which the whole school is in no small degree liable. To these three academics, a fourth and fifth are added by some writers: of which Philon and Antiochus are produced as the representatives. The latter was the friend of Cicero and other distinguished Romans. Neither of them can in any justice be named academics, their doctrines being in fact, in most points, of a diametrically opposite nature.

Academy (Gr. *ἀκαδημία*). A society of learned men, associated for the advancement of the arts or sciences. The name is derived from that of a place near Athens, where there was a famous school for gymnastic exercises [GYMNASIUM], at which also philosophy was taught, and the sophists gave their lectures. But the first institution of which we read, at all resembling our modern academy, was the Society of Scholars, established at Alexandria by Ptolemy Soter. The Jews in various cities, the Constantinopolitan emperors, and the Arab caliphs, founded societies of the same description. Charlemagne, among his various efforts for the propagation of literature, collected an association of learned men, who read and compared the works of antiquity, and gave themselves, in their academic intercourse, the assumed names of different ancient authors. But this institution was dissolved at the death of Alcuin; nor do we find any memorial of a similar society, except a few among artists, chiefly in France, until after the taking of Constantinople by the Turks, when the Greek scholars driven into Italy held literary meetings, which gradually assumed a more regular form. About 1560 a society, called the *Academia Secretorum Naturæ*, was founded at Naples, in the house of Baptista Porta, but was abolished by a papal interdict. It was, however, succeeded by the *Academia Lyncei* at Rome, of which Galileo was a member, the objects of which, like those of the former, were chiefly connected with the pursuit of natural history. From the beginning of the seventeenth century academics multiplied in Italy. Among the most eminent of those which bore a philosophical character, was the *A. del Cimento*, at Rome, in that century; and, in more recent times, the Academy of Sciences at Bologna deserves to be mentioned with honour. But Italy has been most prolific in academies of literature and philology, which form by far the greatest number in the catalogue of 550 such institutions which have been enumerated as existing or having existed in that country. A general and somewhat ridiculous fashion prevailed in the seventeenth and eighteenth centuries among literary men of that country, of forming themselves into societies for the promotion of literary objects, to which they gave fanciful symbolic names, every member assuming in his own person some analogous appellation. Some of these societies have done real service to literature,

ACADEMY

but by far the greatest number have contented themselves with multiplying insipid addresses and sonnets. Among the most celebrated was the A. degli Arcadi, at Rome, of which the meetings were held in a meadow, and the members enacted shepherds and shepherdesses: it was founded about 1690, and still subsists, having various affiliated societies in other places. The A. degli Umidì, one of the oldest of these associations, became afterwards the Florentine Academy. The A. degli Intronati (of the Deaf), degli Umoristi (of the Humorists), and many others with similar quaint appellations, have acquired celebrity in Italy. Of her philological academies, the most illustrious is that della Crusca (of the Sieve), at Florence, which, by the publication of its dictionary, established the Tuscan dialect as the standard of the national language; it is now incorporated with the A. Fiorentina. In France, the Académie Française was founded in 1635 by Cardinal Richelieu. It was an association formed for the purpose of refining the French language and style; and, although in its first period it was chiefly remarkable for the adulation which it bestowed on its vain though able founder, it became, in process of time, by far the most celebrated and influential of all European literary societies. It consisted of forty members, and a place among them was eagerly sought after, for a long period, as one of the highest honours which could be attained by an author. Like that of la Crusca, it published a Dictionary of the French language, in 1694. The Royal Academy of Sciences was founded by Louis XIV. in 1666, and published 130 volumes of memoirs, up to the year 1793, when it was abolished by the Convention. The Academies of Painting and Sculpture, and that of Inscriptions and Belles Lettres, were the other two principal academies of Paris. The latter was founded by Colbert in 1663, and remodelled in 1701. At the Revolution all four were abolished; and, in 1795, at the suggestion of Condorcet, the National Institute of France was established in their stead. It consisted of four classes, arising out of the four academies of which it was composed. According to its reorganisation by Napoleon, in 1806, these classes were remodelled, and each of them consisted of a certain number of sections, each furnished with a specified number of acting and corresponding members. The first class, or that of sciences, had sixty-three members, and 100 correspondents; that of languages, forty, and sixty correspondents; that of history and antiquities, forty, and sixty correspondents; that of the arts, twenty-eight, and thirty-six correspondents. The first, third, and fourth, each named eight foreign associates. In 1816, the Institute was again remodelled by Louis XVIII. The four classes again took the name of academies, and became more independent of each other, their joint property being managed by a commission of eight members, two from each, under the superintendence of the minister of the interior. The first academy (that of sciences) retained the same number of

members. The second and third were reduced to thirty-eight and thirty-seven respectively; the fourth, increased to forty. To the Academy of Inscriptions and Belles Lettres, and that of Sciences, was added a class of free academicians, of the number of ten, with no privilege except that of attendance; the Academy of Arts had the right to choose its own number of free members.

Of similar institutions in Germany, the oldest was the Academia Naturæ Curiosorum, a scientific association, founded in 1662, in Franconia; afterwards taken under imperial protection, when it received the name of the A. Cæsareo Leopoldina. The Royal A. of Sciences, at Berlin, was founded in 1700 by Frederick I. of Prussia: Leibnitz was its first director. The Imperial A. of Sciences at St. Petersburg was founded by Catharine I., and endowed by Catharine II. with great munificence, but established on the French model: she separated from it the A. of Arts.

In England (of public institutions), the name academy has been chiefly confined to associations for promoting the arts. The Royal Academy of Arts was founded in 1768, and consists of forty members; it has separate professors of painting, architecture, anatomy, and perspective; and a council of nine is elected annually. In this year (1863), a Royal Commission has proposed considerable changes in its constitution. The A. of Ancient Music was founded by private association in 1710: the Royal Academy of Music, under the patronage of George III., but dissolved shortly after. Our principal literary and philosophical societies, answering in character to the branches of the French Institute, are:—1. The Royal Society of London, which is confined to objects of a scientific character. It had its origin as early as 1645, but was established by royal charter in 1662. Its acts have been published, under the name of *Philosophical Transactions*, from 1665 to the present day. 2. Those of the Antiquarian Society, which was established in 1751, are published under the title of *Archæologia*. 3. The Society of Arts originated in 1718. 4. That of Literature in 1823. Besides these, there are numerous societies which bear the name of the peculiar branch of science to which their exertions are confined. The Royal Society of Edinburgh obtained a charter in 1783, and another, with more liberal provisions, in 1811. Among the most valuable published transactions of academies and similar societies, besides those already mentioned, are those of Colbert's A. des Inscriptions et Belles Lettres (fifty vols. 4to, from 1701 to 1793): those of the Institute, being continuations of the memoirs of the former academies of which it was composed: those of the A. Royale des Sciences et Belles Lettres at Berlin; at first in Latin, then in French (from its remodelling in 1744 by Frederick the Great), now in German. The 'Acta' of the Imperial Academy of St. Petersburg. The 'Commentarii' of the A. of Bologna. The 'Antichità

of Ercolano,' published by the Herculean Academy of Naples.

Academy Figure. In Painting, a drawing usually made with black and white or tinted chalks, on plain or tinted paper, after the living model. Oil-studies from the Life School, in the Academy, are also called Academy Figures. Such studies by Mulready and Etty are now highly valued as works of art.

Acadialite, or Acadiolite. A variety of Chabazite, probably containing an admixture of quartz. The colour (wine-yellow, or flesh-red passing into white) is arranged in a tessellated manner in some crystals, the angles being nearly colourless. The term Acadialite is derived from *Acadia*, a former name of Nova Scotia, where the mineral is found.

Acajou. The French name for mahogany; also a name sometimes applied to the Cashew nut, *Anacardium occidentale*.

Acalephans, Acalephæ (Gr. ἀκαλήφη, *a nettle*). A class of radiate invertebrate animals, so called on account of the singular property possessed by most of the species therein comprehended, of irritating and inflaming the skin when touched. The class includes the animals called 'medusæ,' 'sea-nettles,' 'jelly-fish,' 'Portuguese man-of-war,' &c.: these are divided by Cuvier into those which have air-bladders for swimming, or the 'hydrostatic acalephans,' and those which have not, or the 'simple acalephans,' and which swim by means of external cilia, or by the contractions and dilatations of their gelatinous body. All the species are marine. Some of them contain as much as 99 per cent. of water, and may therefore almost be described as 'living water.'

Acamptosomes (Gr. ἀ, neg., κάμπτω, *I bend*, and σῶμα, *the body*). An order of cirripeds including all those in which the body is entirely enveloped in a calcareous compound shell, and so attached that it cannot be unfolded and protruded.

Acanthaceæ. [ACANTHUS.] A natural order of monopetalous exogenous plants, in which the genus *Acanthus* is stationed. They have irregular didynamous flowers, and are particularly known by their calyx being imbricated in two broken whorls, and by their seed growing from hooks on the placenta. Many of this order have beautiful flowers, others are mere weeds. They are found wild only in hot or temperate climates.

Acanthia. [ACANTHUS.] The name of a genus of hemipterous insects of the tribe *Coreisa*, characterised by a long and straight rostrum, sheathed at its base, or through its entire length; labrum very prominent; eyes of large size; and the head presenting, at its junction with the thorax, neither a neck nor a sudden constriction. In some of the species (subgenus *Syrtris*), the anterior pair of legs terminate in a monodactyle chela, or forceps claw, like that of the crustacea, adapted for seizing a living prey.

Acanthocephalans, Acanthocephala (Gr. ἀκανθος, *a thorn*, and κεφαλή, *a head*, *spiny-*

headed). An order of intestinal worms, or entozoons, which attach themselves to the mucous coat of the intestines by means of a proboscis surrounded with minute recurved spines.

Acanthoide (Gr. ἀκανθα, *a spine*). A mineral apparently related to Breislackite. It occurs in dark brown fibres passing into reddish-brown, disseminated in lava; and in very slender and silky, whitish needles, in a Vesuvian lava erupted in 1821.

Acanthophis (Gr. ἀκανθα, *spine*, and ὄφις, *serpent*). A genus of venomous serpents, allied to the viper, peculiar to Australia, and characterised by a horny spine, simulating a sting, at the end of the tail.

Acanthopods, Acanthopoda (Gr. ἀκανθα, and πούς, *a foot*, *spine-footed*). This name is applied to a tribe of clavicorn coleopterous insects, including those species which have spiny legs.

Acanthopteri (Gr. ἀκανθα, *spine*, and πτερυξ, *a fin*). An order of fishes characterised by possessing the endoskeleton ossified; fins with one or more of the first rays unjointed or inflexible spines; ventrals in most beneath or in advance of the pectorals; swim-bladder without air-duct. It is divided into two suborders, CTENOPODI and CYCLOPODI [each of which see]. Cuvier's first order of fishes, *Acanthopterygii*, was characterised by the bony spines which form the first rays of their dorsal and anal fins, and generally, also, the first ray of the two ventral fins.

Acanthurus (Gr. ἀκανθα, *a spine*, and οὐρά, *a tail*). A genus of spiny-finned fishes, characterised by trenchant and serrate teeth, and by having a strong moveable spine, sharp as a lancet, on each side of the tail, by means of which these fishes have the power of inflicting very severe wounds.

Acanthus (Gr. ἀκανθος). A spiny herbaceous plant with pinnatifid leaves, and large whitish flowers enveloped in spiny bracts, found in various parts of the Levant.

ACANTHUS. Used in ornament, its leaf is the chief decoration of the Corinthian capital, so called from the tradition that it was first so applied by Callimachus of Corinth, about 400 B.C. It is also the chief foliage of Roman scroll-work; but there is a difference between the Greek and Roman leaf: the former uses the *Acanthus spinosus*, or prickly acanthus; the latter the *Acanthus mollis*, the brank-ursine of our islands. (Wornum, *Analysis of Ornament*, &c.)

Acardia. A term applied to a genus of fossil ostracean bivalves, in which the hinge (cardo) is wanting, and the flat valve is applied to the convex valve, like a lid to a vessel; the two having been connected only by the adductor muscle.

Acari (Gr. *a mite*). In Entomology, the term is restricted to the tracheary arachnidans which have either a single-jointed chelicer, or pincer representing an antenna, or a suctorial mouth. All the species are extremely minute or even microscopic, as the cheese-mite (*Acarus*

ACAULIS

domesticus), and many of them parasitic; of the latter, the itch-insect (*Sarcoptes scabiei*) is a remarkable example. The mites are active insects, and possess great powers of life, resisting for a time the application of hot water, and of alcohol.

Acaulis (Gr. ἀκαυλός). Literally stemless, but applied to plants when the stem is very short, and not apparent.

Acaulose (Gr. ἀ, priv., and καυλός, a stem). In Botany, a term used for those plants which have no stem.

Accapitum. In feudal times, money paid by a vassal on his admission to a feud.

Accedas ad Curiam (Lat. *that you go to the court*). In Law, the title of a writ which removed a plaintiff from an inferior court, generally the county court, the issuing of which was a preliminary to trying a question of right upon a distress of goods by the proceeding called REPLEVIN. It is now disused.

Acceleration (Lat. *acceleratio, a hastening*). In Mechanics, the increase which takes place in the velocity of a moving body. The acceleration is said to be *uniform or variable*, according as in equal intervals of time, however great or small, the increase of velocity is the same or different.

The first law of uniformly accelerated motion at once follows from this definition; it is expressed by saying that *the velocity is proportional to the time* which has elapsed since the motion commenced. The second law, according to which *the space described is proportional to the square of the time*, is a simple consequence of the first. For this space is obviously the same as that which would be described by a second body moving for an equal period with an invariable velocity equal to half that which the first body finally acquires. Now this space is proportional not only to the time, but also to the velocity; which latter, by the first law, is itself proportional to the time; the space in question therefore is proportional to the square of the time.

From these laws it follows, too, that in uniformly accelerated motion, *the velocity is proportional to the square root of the space* described from the position of rest.

Uniformly accelerated motion is the result of the incessant action of a force of constant intensity. In fact, the action of such a force may be conceived to consist of equal impulses imparted at equal and very small intervals of time. Since, therefore, by Newton's first law, a body is incapable of altering its own state of rest or motion, the aggregate effect of such impulses, in other words, the acceleration, must be proportional to their number, that is to say, to the number of intervals of time which have elapsed, or, more simply, to the time itself as stated in the definition.

The most familiar, if not most perfect, example of uniformly accelerated velocity is presented by the fall of bodies in consequence of the earth's attraction, which latter force varies inappreciably at the distances accessible to us.

ACCENT

Accordingly the above two laws, after making allowances for errors of observation, resistance of the air, &c., have been verified by experiment. [GRAVITY and GRAVITATION.] All that has been said of uniformly accelerated motion applies of course (*mutatis mutandis*) to uniformly retarded motion, an example of which is presented whenever a body is projected vertically from the earth's surface. The height to which such a body will rise will obviously be the same as that through which it must descend in order to acquire a velocity equal to the one with which it was projected.

Acceleration of the Fixed Stars.

The apparent greater diurnal motion of the fixed stars than of the sun; in consequence of which they daily come to the meridian of any place at an earlier hour of the solar day than they did on the day preceding. Thus, a star which to-day passes the meridian at six o'clock, mean time, will pass the meridian to-morrow three minutes and fifty-six seconds before six o'clock, the difference in time being equal to that between the lengths of a solar and sidereal day. [DAY, SIDEREAL.]

Acceleration of the Moon. An increase of the mean angular velocity of the moon about the earth; in consequence of which, the time of her mean periodic revolution is somewhat shorter than it was many centuries ago. This acceleration is exceedingly small, amounting only to about ten or eleven seconds of a degree in a century. It was discovered by Dr. Halley from a comparison of very ancient with modern observations, and was confirmed by an examination of the observations of the Arabians in the 9th and 10th centuries. Its physical cause long occasioned great perplexity to mathematicians, and was at length detected by Laplace. It depends on a very slow secular diminution of the eccentricity of the earth's orbit. One of the greatest discoveries in physical astronomy is, that all variations in the elements of the planetary system are periodic. Some centuries after the present time, the eccentricity of the earth's orbit will arrive at its minimum value, and then begin to increase. When this period arrives, the mean motion of the moon, which for many centuries has been accelerated, will begin to be retarded. [PERTURBATION.]

Acceleration of the Planets. The motion of a planet in its orbit is variable, being quicker or slower, according as the planet is at a less or a greater distance from the sun. Hence, in moving from the apogee to the perigee of the orbit, the motion of a planet is accelerated; and, on the contrary, in moving from the perigee to the apogee, the motion is retarded.

Accent (Lat. *accentus*). In ordinary language, the greater or less stress laid in pronouncing on each syllable of a word is termed the accent of that syllable. But the accent of a Greek syllable is a species of tone, respecting which very contradictory notions prevail among modern commentators, and of

ACCENTOR

which it is indeed difficult, to form any accurate conception. The history of the employment of accentual marks in writing the Greek language is extremely obscure. They are found in manuscripts of considerable antiquity. In our pronunciation of Greek, they are wholly neglected. But the modern Greeks pronounce their language, in general, laying the stress on the accented syllables, and neglecting the quantity. The mark of the acute accent is ' ; of the grave ` ; of the circumflex, which is a compound of the other two, ^ or ~. But every syllable which has no accentual mark is said to have the grave accent; the grave being only marked on final syllables of words which have no acute accent on any syllable. These three accentual marks are also employed in the French language; but in it they are only employed, for convenience, to mark a difference in the pronunciation, not in the accent; the modifications of the vowel sounds not being all of them expressed by distinct letters.

ACCENT. In Music, a certain stress or forced expression laid on certain parts of a bar or measure. The first note of a bar has the strongest accent, but subordinate or weaker accents are also laid on the first notes of any subordinate divisions of the bar. For example, in a bar of eight quavers, the first has a strong accent, the third, fifth, and seventh weaker accents. In a bar of nine quavers, the first has a strong accent, the fourth and seventh weaker ones. Sometimes an abnormal accent is laid on what would otherwise be a weak note. This is called *emphasis*, and its skilful use is a great beauty in composition.

Accentor. A genus of seed and insect-eating passerine birds, of which the hedge-chanter, or, as it is commonly called, the hedge-sparrow (*Accentor modularis*), is a well-known example.

Acceptance. [BILL OF EXCHANGE.]

Acceptor (Lat.). [BILL OF EXCHANGE.]

Accessory or **Accessory** (Fr. *accessoire*). In English Law, an accessory to an offence is one who is not the chief actor, or present at its performance, but is concerned therein, either before or after the fact. An accessory before the fact is one 'who, being absent at the time of the crime committed, doth yet procure, counsel, or command another to commit a crime.' An accessory after the fact is one who, knowing that a felony has been committed by another, receives, relieves, comforts, or assists the felon. The law of accessories and abettors is now regulated by 24 & 25 Vict. c. 94. [LAW, CRIMINAL.]

ACCESSARY. In Painting and the Fine Arts, is a term which extends to everything introduced into a work that is not absolutely necessary, or only illustrative. In an historical picture, for instance, the figures which are in action are the principal objects; by them the story is told; all the rest are accessories. Especial care is to be taken that they be so selected and disposed as not to interfere with

ACCIDENTAL POINT

the principal group; hence the ancient painters and sculptors were very shy of using them, lest the eye should be drawn away from the principal group, and its interest be thus lessened or destroyed. Objects or landscapes, as well as figures, are accessories.

Accession (Lat. *accessio*). In International Law, the act by which one power enters into engagements originally contracted between other powers. The accession of a sovereign is the period at which he assumes the sovereignty, and in hereditary monarchies takes place immediately on the decease of his predecessor.

Accidents, per accidens (Lat.). A term used by the older philosophers to denote an effect not following from the nature or essence of the thing, but from some accidental quality. It is opposed to *per se*. Thus, fire burns *per se*; heated iron burns *per accidens*.

Accident. In Logic, one of the predicables: in its strictest logical sense, it is that which may be absent from or present in the subject, the essence of the species to which the subject belongs remaining the same. Thus, if it be predicated of a man, that he is 'walking,' or that he is 'a native of Paris,' the first expresses what is termed a separable accident; the latter, an inseparable; i. e. the individual may cease to walk, but cannot cease to be a native of Paris; but neither of these alters the species, man, to which the individual belongs. It is to be observed, with regard to the accident, as well as the other predicables, that they exist only relatively to each other; so that the same quality may be accidental when predicated of the species, which is a property when predicated of the individual. Thus, 'malleability' is an accident of the subject 'metal,' because many metals are not malleable. But it is one of the properties of gold, iron, &c., as distinguishing these from the non-malleable metals. [PREDICABLE.]

Accidental. In Heraldry, an additional mark in a coat of arms which may be either retained or omitted without altering its character.

Accidental Colours. Colours depending on the hypersensibility of the retina of the eye for complementary colours. If we look for a short time steadily with one eye upon any bright-coloured spot, as a wafer on a sheet of paper, and immediately after turn the same eye to another part of the paper, a similar spot will be seen, but of a different colour. If the wafer be red, the imaginary spot will be green; if blue, it will be changed into yellow; the colour thus appearing being always what is termed the complementary colour of that on which the eye was fixed.

Accidental Point. In Perspective, the point in which a straight line drawn from the eye, parallel to another straight line, cuts the perspective plane. It is the point in which the representations of all straight lines parallel to the original straight line concur when produced. It is called the accidental point, to

ACCIDENTALS

distinguish it from the principal point, or point of view.

Accidentals. In Music, are those flats and sharps which are prefixed to the notes in the course of a movement, and are not indicated by the signature at the commencement.

ACCIDENTALS. In Painting, are those fortuitous or chance effects, occurring from luminous rays falling on certain objects, by which they are brought into stronger light than they otherwise would be, and their shadows are consequently of greater intensity. This sort of effect is to be seen in almost every picture by Rembrandt, who used them to a very great extent. There are some fine instances of accidentals in Raphael's Transfiguration, and particularly in the celebrated picture, the *Notte* of Correggio, in which the light emanates from the infant Christ. With these effects may be classed such accidental lights as those from a forge or a candle, or some such object, of which the use is extremely important to the painter of still life.

Accipitres (Lat. *accipiter*, a hawk). The name of the Linnæan order including the birds of prey.

Acclimatise (Lat. *ad, to*, and *clima*, a climate). The supposed art of cultivating exotic plants so as to inure them to a climate different from that which is natural to them. An acclimatised plant or animal is said to differ from a naturalised one, in always requiring the assistance of art for its continuance in the adopted climate; the naturalised plant or animal continuing its kind without any care from man. It is, however, to be observed that what passes under these terms is frequently nothing more than the fortunate discovery that some plant or animal, which had hitherto been found in a warm climate, would thrive equally well in a cold one. It is doubtful whether any case of true acclimatisation is known among plants.

Accolade (Fr). The slight blow given to the neck or shoulder, on dubbing a knight.

Accompaniment. In Music, the instrumental part of a composition which moves with the voice, to which it is to be kept subordinate. Also, the parts which in a concerted piece move with a particular instrument, whose powers it is the object of the composition to exhibit.

ACCOMPANIMENT. In Painting, any object accessory to the principal subject, and serving to ornament or illustrate it.

Accord. [CONCORD.]

Accordion (Ital. *accordare*, to harmonise). In Music, a free reed portable instrument, something like the concertina, but inferior.

Account Stated. In Pleading (English Law), a 'count' in an action whereby the plaintiff alleges that the defendant is indebted to him in a certain amount on a statement of accounts between them.

Accountant-General. The principal or responsible accountant in the offices of Excise and Customs, India House, Bank of England, &c. The accountant-general of Chancery is an

ACEPHALOCYST

officer appointed by act of parliament to receive all the money lodged in court. He keeps his account with the Bank of England, which is responsible for all the sums lodged there by him.

Accrescent (Lat. *accrescens*, part. of *acresco*, I grow). In Botany, when an organ is persistent and increasing in size; as the calyx of the winter-cherry, which becomes enlarged after the plant has flowered.

Accrescimento (Ital.) In Music, the increase, by one half of its original duration, which a note gains by having a dot appended to the right of it.

Accumbent (Lat. *accumbens*, part. of *accumbere*, to lie down). A botanical term used in cases where one part of an organ is applied to another by its edge; in contradistinction to *incumbent*, where one part is applied to another by its back or face. These terms are principally employed among Brassicaceous (Cruciferous) plants.

Accumulation of Power. Power is said to accumulate when a certain force is exercised upon a body in motion, which is not able to be absorbed by that motion; or when a force is exercised upon a body in repose, which is not capable of relieving the power so accumulating. The measure of the power thus developed is to be found in the capacity of the machinery in action to resist the force thus exercised; or in the vis inertia of the body impressed with the motion, together with any additional efforts it may communicate. The accumulation of force is a great element of the blow with which a heavy body strikes the ground when falling from a height: it is also a matter of serious consideration with the locomotive builder, or the mechanical engineer, in designing their machinery. [GRAVITY; LOCOMOTIVE; STEAM ENGINE.]

Accusative Case. That inflection of the noun which expresses the passing over of an action from one substance to another: it consequently follows verbs active in all languages. The English language retains the inflected case only in the pronouns. [GRAMMAR.]

Acephalans, Acephala (Gr. *ἀκεφαλος*, headless). A term applied to a class of molluscous animals, comprehending those which are without a head. The class is subdivided, according to the modifications of the respiratory organs, into the 'Lamello-branchiate,' 'Pulmo-branchiate,' and 'Hetero-branchiate,' or tunicate orders [which see]. The oyster, lamp-cockle, and squirter, or ascidia, are their several representatives. In the system of Cuvier it includes only the lamello-branchiate and hetero-branchiate orders, or the *Acephala testacea*, and the *Acephala nuda*. [CONCHIFERA.]

Acephali. In Ecclesiastical History, a name given to an Egyptian sect which renounced communion with the patriarch of Alexandria, because the latter had subscribed to the Henoticon of Zeno, A.D. 482. (Gibbon, *Roman Empire*, ch. xlvii.)

Acephalocyst (Gr. *ἀ*, priv., *ἐγκέφαλος*, brain, and *κύστις*, bag). A hydatid, or sub-

ACEPHALOPHORES

globular or oval vesicle, found in the cellular tissue, and filled with fluid. Its animal nature has been asserted by Kuhn and other zoologists. It is, however, probably a mere form of morbid and dropsical cell.

Accephalophores, Accephalophora (Gr. ἀκέφαλος, and φέρω, *I bear*). The name given by Blainville to a class of molluscan animals corresponding to the Accephala and Brachiopoda of Cuvier.

Accephalous. A Botanical term, occasionally employed to designate ovaries, the style of which springs from their base instead of their apex, as in *Lamiaceæ*.

Acer (Lat.). A genus of hardy trees, comprehending the common maple, the sycamore, and various kinds of American maples. Their wood is not of much value, being usually light and perishable; but the knotted parts of *A. campestre* furnish the pretty bird's-eye maple of cabinet-makers. The sap of *A. saccharinum* is so sweet that sugar of good quality is prepared from it in North America. *A. platanoides*, the Norway maple, is one of the best trees for planting in places exposed to the sea air.

Aceraceæ. [ACER.] A small natural order of polypetalous exogenous plants, comprehending the genus *Acer*, and a few others. It consists of trees, or at least of woody plants, inhabiting the temperate parts of the world; their most essential character consists in their samaroid dicarpellary fruit, connected with broken-whorled calyx, and unsymmetrical flowers without scales at the base of the petals. The uses of the order are the same as those of *Acer*.

Acerans, Acera (Gr. ἀ, *without*, and κέρα, *a horn*). A name applied to a family of apterous insects, characterised by the absence of antennæ; and to a family of gasteropodous mollusks, including those species which have no tentacles.

Acerdese (Gr. ἀκερής, *unprofitable*). The name given by Beudant to Grey Oxide of Manganese [MANGANITE], because it is of little use in the arts, compared with Pyrolusite, which it greatly resembles.

Acetic Acid (Lat. acer, *the maple*). An acid obtained from the sap of the maple tree.

Acerose. The word literally means chaffy (Lat. panis acerosus, *chaffy* or *brown bread*). Botanists apply the term to leaves of a narrow, stiff, and pungent nature, like those of fir trees.

Acerra (Lat.). A small altar, placed by the Romans near the couch on which a dead body was laid. Incense or other perfume was burnt upon it, originally, no doubt, to correct any offensive smell arising from the corpse. The name was also applied to the incense box itself.

Acetabulum (Lat. *a vinegar cresset*). A term applied to the suckers on the arms of the cuttle-fish and other dibranchiate cephalopods, which have been, hence, recently termed *acetabulifera*. These suckers were called by Aristotle *kotuloi*, which Taylor has erroneously rendered 'joints,' in the English translation of the *History of Animals*. In Anatomy,

ACETYLE

acetabulum signifies the cavity of the hip-joint. In Entomology it is the socket on the trunk in which the leg is planted.

Acetal (Lat. acetum, *vinegar*). A colourless inflammable liquid, obtained by the action of spongy platinum upon the vapour of alcohol; it is convertible by slow combustion into *acetic acid*.

Acetamide. A white crystalline body, derived from ammonia by replacement of an equivalent of hydrogen by acetylene. It is soluble in water.

Acetanilide. A crystalline solid derived from aniline by replacement of an atom of hydrogen by acetylene. It is soluble in hot water.

Acetarious Plants (Lat. acetaria, *salad*). Plants used in salading; such as lettuce, mustard and cress, endive, &c.

Acetates. Salts containing acetic acid. [VINEGAR.]

Acetic Acid. The pure acid contained in vinegar. It is a pungent acrid liquid; its odour, when diluted, is agreeable and refreshing; when perfumed, it is known under the name of *aromatic vinegar*.

Acetic Ether. This liquid is a compound of acetic acid and ether. Its odour somewhat resembles that of apples. It is an odoriferous and flavouring constituent of many wines, and is easily made artificially by distilling a mixture of alcohol, oil of vitriol, and acetate of potash.

Acetification. The process by which wine, beer, &c., become converted into vinegar. It consists in the direct absorption of oxygen from the air by the alcohol contained in the liquors.

Acetines. Combinations of acetic acid with glycerine. They are oily bodies, and are prepared artificially.

Acetometer. A hydrometer used in determining the strength of acetic acid.

Acetone (Lat. acetum). When acetate of lime, baryta, or lead, is subjected to dry distillation, a limpid colourless liquid is obtained, to which the above name has been given: it has a penetrating aromatic odour, and is highly inflammable: its ultimate components are 8 atoms of carbon, 8 of hydrogen, and 1 of oxygen.

Acetonine. An alkaline liquid derived from the action of ammonia on acetone.

Acetonitrile. A liquid containing the carbon and hydrogen of acetic acid associated with nitrogen. Its more recent name is cyanide of methyle.

Acetous Acid. [ALDEHYDIC ACID.]

Aceturide. Urea in which hydrogen is replaced by acetylene.

Acetylamine, Acetylia, or Diethyl-lexia. An organic base derived from a double atom of ammonia by the replacement of two double equivalents of hydrogen by two of ethylene.

Acetylene. The hypothetical radicle of the acetic compounds: it is composed of four atoms of carbon and three of hydrogen. Its symbol therefore is C_4H_3 , and that of the acetic acid $C_4H_5O_2$.

ACETYLENE

Acetylene. Of all known hydrocarbon gases this contains least hydrogen. It is present in small quantities in coal-gas, and has recently been formed from its elements artificially by passing a current of electricity from carbon points through hydrogen. It is interesting as the starting-point from which a number of organic bodies may be formed.

Achaean League. A confederacy which existed from very early times among the twelve towns of the province of Achaia, in the north of the Peloponnesus. It was broken up after the death of Alexander the Great, but was set on foot again by some of the original cities, A.C. 280, the epoch of its rise into great historical importance. From this time it gained strength, and finally spread over the whole Peloponnesus, though not without much opposition, principally on the part of Lacedaemon. It was finally dissolved by the Romans, on the capture of Corinth by Mummius, A.C. 147. The two most celebrated leaders of this league were, Aratus, the principal instrument in its extension, and Philopomen, the contemporary and rival, in military reputation, of Scipio and Hannibal. (Polybius, i. ii.; Pausanias, i. vii.; Thirlwall, *History of Greece*, ch. lxi.; Freeman, *History of Federal Government*, vol. i. ch. v.; Clinton, *Fasti Hellenici*.)

Achene or **Achenium** (Gr. ἀχνη, and χάλυξ, *I gape*). A small bony fruit, containing a single seed, which does not open when ripe.

Achatina. A genus of terrestrial gastropods, known by the trivial name of agate-snails: characterised by an oval oblong ventricose shell, striated longitudinally; with the aperture ovate and never thickened or reflected, and a smooth, straight columella, truncated at the base. All the species are oviparous, and one, the *Achatina Zebra*, produces eggs with a hard, white, calcareous shell, and as large as those of the sparrow.

Acheron. A river in the nether world of Hades, usually derived from the Greek word ἄγες, as if flowing with pain and sorrow. Two rivers of the same name, one in Thesprotia, the other in Italy, were supposed, from the foulness of their waters, to be connected with this stream. The name probably comes from the root to which belong *Achelous*, *Arius*, *Orus*, and the many other variations, all expressive of flowing waters.

Achievement (Fr. *achèvement*, from *achever*, to accomplish). In Heraldry, this term denotes generally a shield of armorial bearings; but is more particularly applied to the funeral shield, commonly called *hatchment*, affixed to the dwelling-house of a recently deceased person.

Achilleine. A peculiar bitter principle procured from the *Achillea millefolia*.

Achilles. [EPIC; HOMERIC POEMS; ILLAD; MYRMIDONS; ODYSSEY.]

Achirite. The name given by Werner to Diopase, after Achir Mahmed, who first brought the mineral from Siberia.

Achlamydeous (Gr. ἀχλμ, and χλα-

ACHROMATISM

μός, *a tunio*). Plants which have neither calyx nor corolla; whose flowers are destitute of all covering.

Achmatite. A variety of lime-and-iron Epidote from Achmatowak. [BUCKLANDITE.]

Achmite. A mineral found near Kongsberg in Norway. It is a double silicate of iron and soda, and is supposed by G. Rose to be an altered form of Pyroxene.

Achroite (Gr. ἀχρ, and χροια, *colour*). The name proposed by Rammelsberg for colourless varieties of Tourmaline.

Achromatism. The destruction of the coloured fringes which accompany the image of an object seen through a prism or lens. Light is not homogeneous, but compounded of rays unequally refrangible, and differing from one another in other physical properties. In passing into a refracting medium, some of the rays are more refracted, or bent out of their course, than others; whence the image of an object, seen through a lens, is rendered confused and indistinct, and appears encircled by a coloured ring. This circumstance presented a formidable obstacle to the use of the telescope; and, accordingly, soon after the invention of that instrument, the utmost efforts of mathematicians and artists were exerted to remove the imperfection. The compound nature of light, and, consequently, the theory of unequal refrangibility, were, however, not known till the time of Newton; and after the true source of the difficulty had been discovered, it continued for a long time to be believed that achromatism was impossible, or that light could not be refracted without being decomposed. Newton himself was led to this conclusion by imperfect experiments. Subsequent discoveries have proved that the conclusion was erroneous, and that the rays of light may be bent without being separated; but, after all the progress that has been made in practical optics, as well as in the theory of colours and light, the subject of achromatism continues to be one of the most delicate and embarrassing, both in regard to theory and practice.

The principles on which achromatism is effected may be briefly explained as follows. On observing the spectra formed by prisms of different substances, it is soon perceived that the different colours, though always ranged in the same order, do not occupy the same relative lengths. Hence it follows, that the primary coloured rays, in passing through different substances, do not undergo the same relative refractions; that is to say, the angle formed by two rays, the red and the violet, for example, is greater when the light is refracted by some substances than when it is refracted by others, though in all substances the violet is more refracted than the blue, the blue more than the green, and so on. The angle formed between the extreme rays of the spectrum measures the *dispersion* of the rays; and it is found by experiment that the dispersive power of common flint glass is to that of crown glass in the ratio of about 3 to 2; so that if a prism of flint glass

ACHROMATISM

give a spectrum three inches long, a similar prism of crown glass will give a spectrum of only two inches.

Two prisms may therefore be so arranged the one behind the other, that the chromatic effect of the first may be neutralised by that of the second, so as to destroy colour, but still retain a certain amount of refraction.

The achromatism of lenses depends on the same principles as that of prisms; but compensation is attended with great practical difficulties, on account of its being necessary to have regard to the spherical aberration.

If the ratios of the dispersion of the different spectral colours were all equal, the achromatism would be perfect when the extreme rays, or, indeed, any two rays, emerge parallel. This, however, is not generally the case; these ratios are in general variable, and, therefore, the angle which renders the red and violet rays parallel is not that which is required for the intermediate colours. It is possible, however, to remedy this defect, by combining a greater number of prisms or lenses. Theoretically speaking, indeed, the number of rays united or rendered parallel is the same as the number of prisms. The achromatic object-glasses of telescopes formerly made in this country, were generally triple—that is to say, consisted of three lenses, namely, a concave lens of flint glass placed between two lenses of crown glass; but almost all the large object-glasses lately constructed consist of only two lenses; the achromatism produced by this combination, though not rigorously exact, being sufficient for optical purposes.

The possibility of refracting light without producing colour was discovered and experimentally proved by Mr. Hall, a country gentleman of Worcestershire, under whose directions an achromatic telescope was made by a London artist in 1733. But, from whatever cause, no notice was taken of Hall's discovery; indeed, it appears to have been entirely forgotten, and contributed nothing whatever to advance subsequent researches. The merit of the discovery of achromatic compensation belongs to John Dollond, who arrived at it through a long course of skilful and systematic experiments undertaken for the express purpose. Its possibility had, indeed, been previously asserted by the celebrated Euler, who, reasoning from the construction of the eye, which, indeed, is a perfect achromatic instrument, proposed various hypotheses for destroying the coloured images. After Dollond's discovery, the subject was examined theoretically by Euler, Clairaut, and D'Alembert, but their profound mathematical investigations led to no practical improvement. The object-glasses made by Peter Dollond (a son of the inventor) were long celebrated throughout Europe as the best that were manufactured. Of late years, however, the science of light has been vastly extended; and the discoveries of Fraunhofer, in particular, have opened up an entirely new view of the composition of the spectrum. The largest and best achromatic glasses have recently been made in

ACIPENSER

Bavaria by Mertz and Steinhil, and in this country by Dalmayer and Cooke.

Achras (Gr. ἀχράς, *a wild pear*). A genus of *Sapotaceæ*, containing the *Sapodilla* plum, *A. Sapota*, whose elliptic fruit, larger than a quince, has an agreeably tasted yellow flesh; but the seeds are aperient and diuretic. They are milky trees, with entire leathery leaves.

Achtaragditte. A doubtful mineral found in greyish-white or greenish-grey pyramidal tetrahedrons, on the banks of the river Achtaragda in Siberia, associated with Idocrase, Wiluite, and Grossular. According to Breithaupt, Achtaragditte is a pseudomorph derived from the alteration of Helvine.

Acicular (Lat. *aculus*, *a needle*). Anything that is slender, sharp-pointed, and rather stiff; as many kinds of prickles on the leaves of plants, &c. In Mineralogy, a term applied to long, slender, and straight prisms.

Aciculate. A Mineralogical name for Needle Ore.

Acid. In common language, any *sour* substance; in Chemistry the term is less restricted, and often applied to all substances which saturate and neutralise the alkalis and other salifiable bases, without other obvious acid properties.

Acidimeter (Lat. *acidus*, *acid*, and Gr. μέτρον, *measure*). An instrument for determining the strength of an acid by its saturating power: it usually consists of a glass tube graduated into 100 equal parts, and containing an alkaline liquor of known strength, the proportion of which, requisite to saturate a given quantity of any acid, is the equivalent of that acid.

[ALKALIMETER.]

Acidulous. *Dim.* of *acid*. Subacid; a term frequently applied to mineral waters containing carbonic acid.

Acinaciform (Lat. *acinaces*, *a scimitar*, and *forma*, *shape*). A name applied to certain succulent leaves and fruits, which resemble the blade of a curved sword or Turkish scimitar.

Acineta (Gr. ἀκίνητα, from ἀ, *priv.*, and κίνησις, *motion*). A genus of *Infusoria*, allied to *Vorticella*; and supposed by many authors to be one of the transformations of that genus, the cyst of which is, according to Stein, converted into an *Acineta* by the protrusion from its exterior of the characteristic knobbed tentacles.

Acinus (Lat., from Gr. ἄκων, *the stone of a grape*). The separate carpels of a succulent fruit consisting of many carpels; as the raspberry. This term is also applied in Anatomy to a cluster of the ultimate secreting follicles of certain conglomerate glands; as the liver.

Acipenser (Lat. *a sturgeon*). The name of a Linnæan genus of the *Amphibia nantes*, characterised by solitary, lateral, linear gill-openings; the mouth, situated beneath the head, retractile and edentulous; feelers under the snout, in front of the mouth. The sturgeon (*Acipenser Sturio*), and most of the other *Amphibia nantes* of Linnæus, form the order *Chondropterygii*, or cartilaginous fishes of Cuvier. The genus *Acipenser* is separated by Agassiz

from the other cartilaginous fishes. It forms a link between the osseous and cartilaginous fishes, having its gills protected by an operculum, and only a single issue, or gill-opening, on each side for the respiratory currents; but at the same time having no rays to the branchiostegal membrane, and having the whole of its true internal skeleton in a cartilaginous state. It is classified by modern ichthyologists in the placogonoid order of fishes. Its flesh, like that of most cartilaginous fishes, is firmer than is usual among osseous fishes, and, having little peculiar flavour of its own, affords ample scope for the skill of the cook in imparting to it an extrinsic zest. In the northern parts of Europe this fish is much more numerous than in the British rivers, and extensive fisheries are established for its capture. The best isinglass is manufactured from the sound, or air-bladder; and caviare is prepared from the roe of the female.

Acis. In the mythology of Ovid, was a son of Faunus and the nymph Symæthis, killed by Polyphemus, because he was loved by Galatea. (Ovid, *Met.* xiii. 750.)

Acknowledgement Money, in Law, paid according to the custom of some manors by copyhold tenants, on the death of a lord.

Acme (Gr. ἀκμή, *a point*). In Rhetoric, the extreme height, or farthest point of pathos or sentiment, to which the mind is judiciously conducted by a series of impressions gradually rising in intensity. [CLIMAX.]

Acollé (*collared*, from Fr. *col*, *the neck*). In Heraldry, denotes animals with collars, &c., about their necks, batons or swords placed saltier-wise behind the shield, or two things joined together.

Acology, or **Akology** (Gr. ἄκος, *a remedy*, and λόγος, *a discourse*). The doctrine of remedies, or of the materia medica.

Acolyte (Gr. ἀκόλυτος, *a follower*). The second of the inferior orders of clergy in the primitive church, according to the Roman Catholic authorities. The Council of Trent declares the inferior orders to be five—subdeacons, acolytes, exorcists, readers, and doorkeepers; considering them all to be of apostolical institution. By the Protestants they are supposed to be merely occasional or local officers. The office of the acolyte, according to the Roman Catholic *Catechismus ad Parochos*, is to follow and serve the superior orders, the subdeacons and deacons, in the ministry of the altar.

Aconite (said to be so named from Acone, a place in the Crimea famous for its poisonous herbs). A genus of exogenous plants belonging to the natural order *Ranunculaceæ*, with white, purple, or yellow helmet-shaped flowers growing in panicles, deeply-cut leaves, and perennial roots of a highly poisonous nature. Those of *Aconitum Lycocotum* are used for the destruction of wolves, and of *A. Napellus* for certain medicinal purposes; they are exceedingly acrid, and act as violent drastic purgatives. The bish root, with which the natives of Nepal poisoned their wells during the advance of the British army into

their territory, was furnished by *Aconitum ferox*. The name aconite has also been given to another plant related to the original genus, namely, *Franthis hycmalis*, or winter aconite.

Aconitic Acid. A crystalline body existing in the aconite and some other plants. Thus, it occurs in the river equisetum, and hence is sometimes termed *equisetie acid*. It is, however, most easily obtained from the residue of the distillation of citric acid, and is therefore occasionally called *citridic acid*.

Aconitine, Aconitina. An intensely poisonous alkaloid contained in the *Aconitum Napellus* or monkshood. It is a solid, forms salts with acids, and is sometimes used by surgeons to produce contraction of the pupil of the eye.

Acontia (Gr. ἀκων, *a dart*). A genus of non-venomous ophidian reptiles, allied to the snakes proper (*Anguis*), but destitute of the bony rudiments of the scapular and pelvic arches. They are known by the trivial name of 'Dart-snakes'; are numerous in species, and distributed over the warmer and more arid parts of the Old World. They were the subjects of fabulous accounts by the ancient naturalists and poets, who attributed to them the power of projecting themselves with so much force and velocity as to transfix the object aimed at, like a hurled javelin, or arrow shot from a bow. This is as untrue as the assertion that they are venomous. The Dart-snakes are amongst the most harmless of their order; their food consists of small worms, insects, and larvae.

Acoraceæ. The natural order of plants which includes the genus *Acorus*. It is distinguished from *Araceæ* only by having its carpels separate, and its leaves in the bud state arranged in an equitant manner.

Acorn. (Sax. accorn, from *sac*, *an oak*, and *cern*, *grain*). The well-known fruit of the oak, and therefore not a term of art, though belonging to architecture from its use as an ornament. In the early ages acorns, it is said, constituted part of the food of man (Ovid, *Metamorph.* i. 106; Virgil, *Georg.* i. 8, &c.). At present they are occasionally used, as in Spain, under the name of Bellotes; but in England never, except for the feeding of pigs, poultry, &c.

Acorus (Gr. ἄκωρος). A plant with sword-shaped leaves and aromatic stems, found abundantly in the meadows of some parts of England. It bears, but very rarely, its flowers in a little greenish-yellow spadix, which appears at a short distance below the end of a leaf-like scape. The leaves, when crushed, exhale a pleasant odour, and are still used for strewing the floors of churches upon the occasion of certain ancient ceremonies. Its stem, or rhizoma, is like that of an iris. It is the *Calamus aromaticus* of the druggists.

Acotyledons (Gr. ἀ, *priv.*, and κοτυληδών, literally, *a hollow or concave part*, but applied by botanists to the seed-lobe). Plants whose embryo has no distinct cotyledons. The term is usually applied to what are more commonly named cryptogamic plants, such as ferns, mosses, lichens, &c., in which there are no seeds,

ACOTYLEDONOUS

properly so called, but which are propagated by undivided spheroidal bodies called spores. The word acotyledon is occasionally used for such plants as *Cuscuta*, *Cactus*, &c., whose embryo, although really of the same nature as those in which cotyledons are usually present, has no obvious division; this mode of applying the term is, however, seldom employed.

Acotyledonous (Gr. ἀ, priv., κοτυληδών, a seed-lobe). Not having cotyledons or seed-leaves. The term is sometimes applied to the cryptogamous plants, in contradistinction to the phanerogamous plants, which latter are either monocotyledonous or dicotyledonous.

Acoustics (Gr. ἀκουστικός, from ἀκούω, I hear). The science of hearing, or of sound. [Music; Sound.]

Acquittal (Fr. acquitter, to free). In Law, a deliverance and setting free of a person from the suspicion or guilt of an offence; also freedom from entries and molestations by a superior lord for services issuing out of lands. There are two kinds of acquittal: 1. Acquittal in deed, when a person is cleared by verdict; and 2. Acquittal in law, as if two be indicted for felony, the one us principal, the other as accessory, and the jury acquit the principal, by law the accessory is also acquitted. (Wharton's *Law Lex.*) But accessories may now be punished as principals.

Acquittance. In Law, the discharge in writing of a sum of money due. An acquittance not under seal is admissible only in evidence, and is not pleadable. An acquittance in full of all demands, is an answer to all debts, except such as are on specialty, which can only be discharged by an instrument of equal force.

Acre (Germ. acker, Gr. ἀγρός, Lat. ager). A measure of land equivalent to 4840 square yards. The acre is divided into 4 roods, and each rood into 40 perches; so that a perch contains 30½ square yards. [MEASURE.] Formerly the acre differed in magnitude in different parts of the United Kingdom. 121 Irish acres were equivalent to 196 English acres; 48 Scotch acres were equivalent to 61 English acres. The French *are* is equivalent to 100 square metres, so that 1000 English acres are equivalent to 40467 French *ares*.

Acresight. A kind of duel, fought in ancient times by single combatants, English and Scotch, between the frontiers of their kingdoms.

Acridians, Acridia (Gr. ἀκρίδιον, dim. of ἀκρίς, a locust). A family of orthopterous insects, having the genus *Acridium* for the type.

Acridium. The name applied by Fabricius to a genus of locusts, characterised by a carinate thorax; filiform antennæ, shorter than the thorax; and equal palps or feelers.

Acrites, Acrita (Gr. ἀκρίτας, not discernible). The lowest division of the animal kingdom, in which there is no distinct discernible nervous system; and in which the alimentary canal is not separated from the parietes of the body, or contained in a distinct abdominal cavity. It is composed of the classes *Infusoria*, *Foraminifera*, and *Amorphozoa*,

ACROPODIUM

[which see]. The division is also termed *Protozoa*.

Acroamatic (Gr. ἀκροαματικός, from ἀκροδομαι, I hear). A term used in the Aristotelian schools, signifying lectures intended only to be heard by that philosopher's intimate friends and disciples, instead of being committed to writing. They were also called *isoteric*, as distinguished from *exoteric*, or those adapted to a common auditory.

Acrodactylum (Gr. ἄκρος, highest or extreme, and δάκτυλος, a digit). In Zoology, the upper surface of each digit.

Acrodus (Gr. ἄκρος, extreme, and ὀδός, tooth). The name of a genus of sharks, characterised by the presence of large polygonal obtuse enamelled teeth, aggregated at the extremity of the jaws. The fishes of this genus are found exclusively in the fossil state.

Acrogens (Gr. ἄκρος, and γίγνομαι, I grow). Plants, otherwise called cryptogamous and acotyledonous. They correspond to ferns, mosses, lichens, &c.; have no sexes; are multiplied by spores instead of seeds; and are remarkable for increasing chiefly in length by additions to their end, and not in diameter by the addition of fresh matter to their outside, as in exogens, or to their inside, as in endogens.

Acroleine (Gr. ἄκρος, and Lat. oleum, oil). An acrid volatile product, formed during the destructive distillation of the fat oils: it appears to arise from the decomposition of glycerine.

Acrolithos (Gr. ἀκρολίθος). In Sculpture, a statue in which the parts not covered with drapery, namely, the face, hands, and feet, were made of marble, the rest being composed of wood. Statues, so made, mark the intermediate stage between the employment of wood only and the construction of the statues termed *chryselephantine*.

Acromion (Gr. ἀκρόμιον, from ἄκρος, highest, and ὤμος, shoulder). A term in Anatomy for the large process which terminates the scapular spine above and outwards, and receives on its articular surface the scapular extremity of the clavicle. It affords attachment to the deltoid and trapezius muscles.

Acromonogrammaticum (Gr. ἄκρος, ὄμος, only, and γράμμα, a letter). A poetical composition in which every verse begins with the same letter as that with which the preceding verse terminates.

Acronyca (Gr. ἄκρος, and νύξ, night). A star or planet is said to be acronyca when it is opposite to the sun, or passes the meridian at midnight. It rises acronyca, when it rises as the sun sets; and sets acronyca, when it sets as the sun rises. The Greek poets designated these different positions of a star, at its rising or setting, with respect to the sun, by the terms *acronyca*, *cosmica*, and *heliaca*; and thereby indicated, in a rude way, the position of the sun in the ecliptic, or the season of the year. [HELICAL.]

Acropodium (Gr. ἄκρος, and πούς, foot). In Zoology, the upper surface of the whole foot.

ACROPOLIS

Acropolis (Gr. *ἄκρος*, and *πόλις*, *city*). The upper town or citadel of a Grecian city. It was usually the site of the original settlement, and was chosen by the colonists for its natural strength. The most celebrated were those of Athens, Corinth, and Ithome. That of Athens was especially remarkable for its buildings and works of art, the Parthenon, Erechtheion, &c. (*Edinburgh Review*, July 1859, art. 'Acropolis of Athens.')

Acrospire (Gr. *ἄκρος*, and *σπείρα*, a curved line). When seeds begin to grow, the part of the germ which afterwards produces the stem shoots forth in the form of a delicate curved thread, and, gradually bursting the outer covering, makes its appearance at the end of the seed. Multsters, especially, call this the acrospire of barley.

Acrostic, or **Acrostich** (Gr. *ἀκρόστιχον*, from *ἄκρος*, and *στίχος*, *line* or *rank*). A short poem, in which the first or last letters of every line form a name or a sentence. Great labour and ingenuity have been exercised in inventing varieties of this and similar curious trifles. Such, for example, is the pentacrostic, in which the initial letter of each verse is repeated five times in the verse, so as to form five repetitions of the same acrostic in different columns.

Acrostolium. [POOP.]

Acrotarsium (Gr. *ἄκρος*; *ῥαρός*, *tarsus*). In Zoology, the upper surface of the tarsus.

Acroteria (Gr. *ἀκροτέρια*, *extremities*). In Architecture, the small blocks, or pedestals, which are placed at the apex and at the extremities of pediments, to receive statues, trophies, or other emblematic sculpture.

Acrydium. [ACRIDUM.]

Acryl. The hypothetical radicle of which acroleine is the hydride.

Acrylic Acid. Oxidised acroleine. It bears the same relation to acryl and acroleine that acetic acid does to acetyl and aldehyde.

Act (Lat. *actus*). In Dramatic literature, a division of a drama, subdivided into scenes. The Greek dramas of the old model were naturally divided into separate portions by the stasima, or choricodes, which occur at intervals, during which the stage was left to the sole occupation of the chorus. Nevertheless, the Greek writers do not notice this division in express terms; nor do we know the origin of the famous rule of Horace, that every dramatic piece should be restrained within the limits of five acts, neither more nor less. The division into acts must be in great measure arbitrary, although rules have been laid down, by various writers, to define the portion of the story or plot which should be contained in each of them. Thus, Vossius lays it down as a rule, that the first act presents the intrigue, the second develops it, the third is filled with incidents forming its knot or complication, the fourth prepares the means of unravelling it, which is finally accomplished in the fifth. [DRAMA.]

Act. In the Universities, an exercise performed by students before they are admitted to degrees. The student proposes certain ques-

ACTINOCRINITES

tions to the presiding officer of the schools, who then nominates other students to oppose him. The discussion is syllogistical and in Latin, and terminates by the presiding officer questioning the respondent, or person who is said to keep the act, and his opponents, and dismissing them with some remarks upon their respective merits. The practice has fallen into disuse at Oxford.

Act of Grace. In Scotch Law, an act passed in 1696, which provides maintenance for debtors while in prison at the suit of their creditors.

Act of Parliament. [STATUTE.]

Acta Diurna (Lat. *daily proceedings*). Among the various important improvements effected by Julius Cæsar may be ranked that of his furnishing the Romans with a species of newspaper. He was the first to order that the *acta diurna* of the senate and the people should be drawn up in a regular form and published. This publication must consequently have, in many important respects, closely resembled a modern newspaper. (Sueton. *In Cæs.* cap. xx.)

Actian Games (Lat. *ludi Actiæ*). Games celebrated in antiquity at Actium in honour of Apollo, hence surnamed *Actius*. The temple of the god was repaired, and the games restored and celebrated with increased splendour, by Octavius, afterwards the Emperor Augustus, in memory of his victory over Mark Antony off Actium.

Actinia (Gr. *ἀκτίς*, a ray). A genus of *Anthozoa* with very numerous tentacles, which extend, like rays, from the circumference of the mouth. They are amongst the most highly organised of the class, having the alimentary sac distinct from the parietes of the body; feeding on shellfish and other marine animals, which they draw into their mouth with their tentacula, and in a short time rejecting, through the same aperture, the shells and indigestible parts. They are of a soft gelatinous texture, and they assume various forms when the tentacles are all expanded, having the appearance of full-blown many-petalled flowers; whence they are called 'sea anemones,' 'sea sunflowers,' &c. (*Phil. Trans.* lxiii. p. 361.)

Actinism (Gr. *ἀκτίς*, a ray). A name recently given to that property of the sun's rays which effects chemical combinations and decompositions, as shown in the processes of photography, in contradistinction to their heating and illuminating powers. [LIGHT.]

Actinocamax (Gr. *ἀκτίς*, a ray, and *καμάξ*, a pale). A name applied by Miller to the fossil shells of an extinct genus of cephalopodous mollusks, apparently connecting the *Belemnites* with the existing *Scipia*. The remains of the *Actinocamax* appear as yet to be peculiar to the chalk formations of England and Normandy.

Actinocrinites (Gr. *ἀκτίς*, a ray, and *κρίνον*, a lily). The name of a subgenus of extinct crinoidan radiated animals, or crininites, characterised by the numerous rows of angular plates, which, being articulated by their margins, constitute the body.

ACTINOGRAPH

Actinograph (Gr. *ἀκτίς*, a sunbeam, and *γράφω*, I write). An instrument for the purpose of registering the variations of chemical influence in the solar rays, the intensity of which has been found to bear no direct relation to the quantity of light, but to vary at different periods of the day and year. The instrument, as contrived by Mr. Hunt, and described to the British Association, 'consists of a fixed cylinder, on which is placed a prepared photographic paper. This is covered by another metal cylinder, which revolves once in twenty-four hours. In this there is a triangular opening divided by fifty bars, through which the paper is exposed to the sunshine. As the time during which the smallest part of the opening allows the paper to be exposed is one hundred times less than the time during which it is exposed by the largest opening, different effects are produced on the paper, and consequently a register for every hour of the day may be numerically kept of the actinic radiation associated with light.' (*British Association Reports* for 1845 and 1846.)

Actinolite (Gr. *ἀκτίς*, a ray, and *λίθος*, stone). A name under which are comprehended the glassy, asbestiform, and granular varieties of Hornblende.

Actinometer (Gr. *ἀκτίς*, a sunbeam, and *μέτρον*, measure). An instrument invented by Sir John Herschel for measuring the force of solar radiation. It consists of a hollow cylinder of glass soldered at one end to a thermometer tube terminating at the upper end in a hollow ball drawn out to a point, and broken off so as to leave the end open. The other end of the cylinder is closed by a silver, or silver-plated, cap cemented on it, through which a screw, working in a collar of leather, passes into the interior of the cylinder, and gives the means of increasing or diminishing the hollow capacity of the cylinder to a small extent at pleasure. The cylinder is filled with a deep-blue fluid (the ammonio-sulphate of copper); a graduated scale is applied to the stem, or thermometer tube, and the instrument is defended from currents of air by being enclosed in a case having the interior of three of its sides blackened, and the fourth, or face, composed of a thick plate of glass.

Before using the instrument for observation, any air-bubbles in the cylinder must be carefully expelled. This is easily effected by means of the screw and the ball at the top of the stem, which serves as a reservoir, and contains a small portion of superfluous liquid. When the ball and stem are both filled, and no air-bubble is left, the fluid is brought down to the zero of the scale by turning the screw.

The general object is to determine the expansion of the liquid produced by the exposure of a given area of the cylinder to the direct rays of the sun during a given interval of time. But as the expansion of the liquid depends not only on the heating power of the sun, but also on the rapidity with which the heat received is radiated away, and on every other circumstance

ACTINOMETER

exerting a thermometrical influence, it is necessary to eliminate those influences. For this purpose the observations are made with the instrument alternately exposed to and screened from the solar rays for intervals of one minute.

On exposure to the sun, the liquid in the stem rises rapidly, and the difference of the readings of the scale at the beginning and end of the interval of exposure shows the combined effect of all the heating and cooling influences. The instrument is then placed in the shade during an equal interval. If during this second interval the liquid remains stationary, then it may be inferred that the rise in the first interval was due to the solar action alone. If the liquid falls during the shade observation, then it is manifest that the solar action is opposed or counteracted by the cooling influences, and the number of divisions through which the liquid falls must be added to the number through which it rose in the interval of exposure, in order to have the measure of the solar action. But if the liquid continues to rise during the shade observation, then it is plain that the action of the solar rays is assisted by other heating influences, and the number of divisions through which the liquid rises in the second interval must be subtracted from the number through which it rose during the first.

The observations are made in triplets; that is to say, the instrument is held in the sun's rays one minute, then one minute in the shade, and again one minute in the sun, an interval of 20 or 30 seconds being interposed at each change for the purpose of noting the readings. The difference of the readings at the beginning and end of each minute interval is taken, and the difference in respect of the second interval is added to or subtracted from the mean of the two differences in respect of the first and third. A complete actinometer observation, however, cannot consist of less than three sun observations and two shade observations intermediate; but the more there are taken the better.

It will be readily seen that the results obtained, as above described, are only relative; some positive determination must therefore be had recourse to before the indications given by any two instruments are comparable. This is a matter of much difficulty. No doubt it is possible to determine for every instrument both the area of the section of the sunbeam which falls on the bulb and is effective in raising the temperature, and also the absolute quantity of liquid in the capillary tube, corresponding to any length on the scale; or, which comes to the same thing, to determine the value of the parts of the scale in water grains, or some other absolute measure. But even this would not be sufficient; for, in so delicate an experiment, the slightest difference in the thickness or composition of the glass would produce discrepancies, and no two plates of glass are ever found to be precisely the same in respect of the proportion of calorific rays they stop or absorb. Hence, the only means of discovering the relation between the results given by two instruments

ACTION

is to make a series of experiments with Loth together, and under precisely the same circumstances. Sir John Herschel proposes to adopt as the *actine*, or unit, that intensity of solar radiation which, at a vertical incidence, and supposing it to be wholly absorbed, would suffice to melt one-millionth part of a *metre* in thickness from the surface of a sheet of ice horizontally exposed to its action in one minute of mean solar time.

In the *Philosophical Transactions* for 1842 Professor Forbes, of Edinburgh, has given an account of some interesting experiments with the actinometer, made by him on the Faulhorn (in Switzerland), for the purpose of ascertaining the difference of solar radiation at the bottom and top of the mountain, and thence the proportional quantity of calorific rays absorbed in passing through a stratum of the atmosphere of a given thickness. This is one of the most useful purposes to which the instrument can be applied. It may also be used for measuring the defalcation of heat in an eclipse of the sun.

The actinometer was first described in the *Edinburgh Journal of Science*, vol. iii. for 1825. For a full description of the instrument, and of the method of using it, see the *Report of the President and Council of the Royal Society on the Objects of scientific Inquiry in Physics and Meteorology*, 1840. [PHOTOMETRY.]

Action. In Mechanics, denotes sometimes the effort which a body or power exerts against another body, sometimes the effect or motion resulting from such effort. Mechanical action is exerted either by percussion or by pressure; in the former case, the effect is instantaneous, in the latter it is continued. In all cases of mechanical action, the effect of the acting body is resisted in an equal degree by the inertia of the body acted upon, which resistance is termed *reaction*; and it is an axiom in mechanics, that action and reaction are always equal, and exerted in opposite directions. Thus, in driving a nail with a hammer, the stroke acts against the face of the hammer exactly with the same energy as against the head of the nail; and in pressing the hand against a stone, the pressure on the hand and on the stone is precisely the same.

Action. In the Military art, an engagement or battle between opposing forces; hence *partial actions*, *general actions*, &c.

Action. In Oratory, the accommodating or suiting of the countenance, voice, and gesture of the speaker, to the matter to be spoken or delivered. This *sermo corporis*, as Cicero calls it, has always been regarded as a most important part of oratory. The ancient masters laid the greatest stress upon it, and Demosthenes asserted that action was 'the beginning, the middle, and the end of the orator's office.'

Action. In Painting and Sculpture, the state of the subject as imagined in the artist's mind at the moment chosen for representation. It must not be confounded with motion, which relates to the mobility of a single figure. Ac-

ACTOR

tion must be true, simple, natural, and connected; and its unity must be preserved, or the action is weakened. In painting, all action represented is supposed to be simultaneous, or the unity of the picture is destroyed.

ACTOR. In Poetry, an event either real or imaginary, forming the subject of an epic poem or play, &c. Thus, the wrath of Achilles forms the action or subject of the *Iliad*, the wanderings of Æneas the action or subject of the *Æneid*, &c.

ACTION. In the stock market in Paris, and other places in France, *action* is the name given to a share of the capital of a joint-stock company.

Actions in Law. Actions in Law were real, personal, or mixed. Actions, real or mixed, for the recovery of real property, were so numerous, prolix, and difficult, that, having practically fallen into disuse, they were almost entirely abolished in 1833. The only case in which (prior to their abolition) they were resorted to in modern times was where, from the machinery of ejectment, one of these four, a simple procedure is now substituted, and the remaining three have been assimilated in practice to personal actions by a recent statute. Actions in common use, i. e. personal actions, are divided into actions of contract and actions of tort, and into local and transitory, in the former of which the place or county where the cause of the action arose must be accurately alleged, for the purpose of the trial taking place there. The allegation is termed the *venue* of the action, from the Norman-French *visne* (Lat. *vicinitas*), *neighbourhood*, because the jury impanelled to try an action came originally from the neighbourhood. In transitory actions it is immaterial. Actions of tort to the person, and all actions of contract, are generally transitory, but under certain circumstances the latter may be local. [PLEADING.]

Active Molecules. [MOLECULES.]

Actor (Lat.), **Actress.** In the flourishing period of the early Greek drama, so long as a certain remnant of religious solemnity was attached to it, there was no degradation in the character of an actor: in fact, the parts of the chorus were often filled by volunteer performers of birth and station. But when the dramatic performers began to form a profession apart, they appear soon to have been regarded with disrespect. In Rome, the first actors were buffoons (known by the Tuscan name of *histriones*), who enacted the grotesque farces imported from Etruria, and the qualification of actor was among the most dishonourable in the period of the republic; nor was any circumstance considered to indicate more decisively the intention of Nero to degrade and subject all classes in the state, than his having persuaded a Roman knight, Laberius, to appear on the stage in the performance of one of his own mimi. Under the dissolute reigns of the first emperors, especially Nero, much favour and countenance was shown to actors. Nero was, however, obliged at last to banish the *pantomimi*, the most popular species of actors, entirely from

Italy, together with their performances, in consequence of the strong party spirit which was excited about them. (Sueton. *Nero*, c. 16.) It seems from Tacitus, that they were soon afterwards restored; again banished by Domitian; restored by Nerva; and finally expelled by Trajan; but, by the time of the reign of the last-mentioned emperor, the dramatic stage was nearly abandoned, and its place wholly occupied by gladiatorial shows and other pageants. In England, the first actors were the servants of great nobles, who performed for their diversion; and when regular theatrical companies were formed, they were long in the habit of putting themselves under the protection of distinguished personages; the companies of the greater theatres, as is well known, retained in modern times the custom of calling themselves servants of His Majesty. Actresses were not known on the English stage until some time after the Restoration: although ladies of quality had frequently, under James and Charles I., performed parts in masques, &c. Kynaston was the last celebrated male performer of female parts: a singular notice of him will be found in Pepys's *Memoirs*. In Roman Catholic countries, actors, even to this time, are under the ecclesiastical restriction of excommunication. [DRAMA.]

Acts of Sederunt. In Scotch Law, statutes made by the Lords of Session sitting in judgment, by virtue of a Scottish act of parliament, passed in 1540, empowering them to make such constitutions as they may think expedient for ordering the procedure and forms of administering justice.

Actuary. Originally a public officer in the Roman courts of justice, who drew up writings, contracts, &c., in the presence of the magistrate; whence his name, from *actus*, an instrument. Actuarii also kept the military accounts of the Romans, and distributed the corn to the soldiers. The clerk who registered the acts and constitutions of the convocation, in the assemblies of that body, was termed *actuary*. A calculator of the value of life interests, annuities, &c., is usually termed in England an *actuary*. [INSURANCE.]

Aculeate (Lat. *aculeatus*, from *aculeus*, a prickle). In Botany, anything covered with prickles; that is, with sharp prominences which originate in the cellular system and have no connection with wood.

Aculeates. In Zoology, a tribe of hymenopterous insects, in which the females and neuters are provided with a sting, generally concealed within the last segment of the abdomen.

Acuminate (Lat. *acuminatus*, from *acumen*, the point of anything). When a leaf or any other body is very much tapered to a point; it is thus distinguished from *acute*, which means sharp-pointed without any tapering.

Acupuncture (Lat. *acus*, a needle, and *punctura*, a puncture). Pricking with a needle. In the East this is a common remedy for painful affections of different parts of the body. It has lately been extensively practised for

the cure of chronic rheumatism, a long and sharp needle being thrust into the affected muscles.

Acute (Lat. *acutus*, sharp). In Music, the height or pitch of a sound or tone, in respect of another. It is opposed to *grave*.

Acute Angle. An angle less than a right angle. [ANGLE.]

Ad libitum (Lat. *at plensure*). In Music, a term applied to an accompaniment which is not essential, and may or may not be performed without interfering with the composition.

Ad quod Damnum (Lat. *to what damage*). A writ sued before the grant of certain liberties and franchises, as a fair, market, &c., which may be prejudicial to the king who grants, or the public; by it the sheriff is directed to inquire what damage may accrue from the grant in question.

Adactyle (Gr. $\acute{\alpha}$, priv., and $\delta\alpha\kappa\tau\upsilon\lambda\omicron\varsigma$, a digit). In Zoology, signifies a locomotive extremity without digits.

Adage (Lat. *adagium*, a proverb). The proverbs of antiquity are collected by Erasmus in a work entitled *Erasmii Adagia*. [PROVERB.]

Adagio (Ital. *leisurely*). In Music, a slow time.

Adamantine Spar. A variety of crystallized alumina, resembling the sapphire in composition, and of extreme hardness. The finest specimens come from India and China. At Bombay it is called *Corundum*.

Adamites. In Theology, a sect in the early ages of the Christian Church, who are said to have professed an exact imitation of the primitive state of innocence. They reappeared in the 15th century in Bohemia.

Adam's Peak, called *Hamalell* by the Sinese, and *Al-rahoun* by the Arabs. A mountain in Ceylon, chiefly noticeable from the veneration with which it has been regarded for ages by Brahmans, Buddhists, Chinese, Gnostics, and Mohammedans. The people make a grand pilgrimage to the summit once a year, and worship near the fabled print of the foot of Buddha. It was first called by the Portuguese the 'Pico de Adam.' (Tennent, *Ceylon*, vol. ii. pp. 132, 133.)

Adamsite. An ash-grey variety of Mica, found in small scales forming lamello-granular masses at Derby in Vermont.

Adansonia. A remarkable African tree, named after Adanson, a celebrated French botanist and traveller. It is called by the negroes *Baobab*. Miscalculations, founded upon the huge diameter of its trunk, have led to the belief that individuals may now exist some thousands of years old. [BAOBAB.]

Adapis. A name originally applied by Gesner to the hyrax or coney of Scripture, and adopted by Cuvier to designate another small pachydermatous, probably artiodactyle, quadruped, now extinct, but the existence and nature of which that great naturalist detected and deduced from three fragments of the head, which were discovered in that immense depository of fossil bones, the gypsum quarries of Montmartre.

The dentition of the *Adapis* is as follows:—each jaw has four trenchant incisors; two conical canine teeth, the upper ones straight, the lower inclined obliquely forwards; and apparently fourteen molar teeth, of which the first is trenchant, and the three or four posterior ones, on each side, like the posterior molars of the *Anoplotherium*. Cuvier supposes the animal to have been about the size of a rabbit, and to have closely approximated the *Anoplotheria*.

Adar (Heb. perhaps fire). The twelfth sacred and sixth civil month of the Jewish year. The leap year was the Veadar (or second *Adar*).

Adder. [VIPER.]

Addiction (Lat. addictio). In Roman Law, the making over of goods or slaves from one to another, by sale or legal sentence.

Addition. In Arithmetic, the first of the four fundamental operations, by which a number is found equal to several others taken together. In Algebra addition includes arithmetical subtraction; by its means several algebraical quantities are incorporated into one expression.

ADDITION. In Law, the personal description whereby a man is distinguished in addition to his name (gentleman, squire, and so forth).

Additive. Something to be added, in contradistinction to *subtractive*, which denotes something to be taken away. The terms additive and subtractive are sometimes applied to algebraic quantities. [POSITIVE QUANTITY and NEGATIVE QUANTITY.]

Adorsed (Lat. ad, to, and dorsum, the back). In Heraldry, that which is placed back to back.

Adductor (Lat. adduco, *I draw towards*). The adductor muscles are opposed to the abductors: they draw together the parts to which they are attached.

Adelphia (Gr. ἀδελφός, a brother). A collection of stamens into a bundle. Linnæus employed this term for those plants in which the stamens, instead of growing singly, combine into one or more parcels, or brotherhoods; thus, Monadelphina signified stamens all connected into one parcel, Diadelphina into two parcels, and so on.

Adelpholite (Gr. ἀδελφός, a brother, and λίθος, a stone). A niobate or tantalate of iron and manganese, with about ten per cent. of water, found at Rajamäki in Finland.

Adenography (Gr. ἀδήν, a gland, and γράφω, *I write*). In Anatomy, that which treats of the glands.

Adenostylem (Gr. ἀδήν, a gland, and στίλος, a column or style). A subdivision of composite plants, comprehending *Tussilago*, *Liatris*, *Eupatorium*, and some other genera, in which the branches of the style are covered with long glandular hairs.

Adophagans, Adephaga (Gr. ἀδωπάγος, voracious). A family of carnivorous and very voracious coleopterous insects.

Adept (Lat. adeptus, from adipiscor, *I obtain*). A distinctive term applied to those alchemists who were supposed to have attained

the great object of their researches, or to have discovered the philosopher's stone.

Adhesion (Lat. adhesio, from adhaereo, *I adhere*). In Botany, a property of vegetable matter by which contiguous parts grow together, and one of the causes of the great diversity of appearance in the organs of plants. Two opposite leaves grow together and form apparently one, through which the stem passes; several in a whorl adhere, and form an involucre; a number of petals adhere, and thus constitute a monopetalous corolla; several stamens adhere, and an adelphia is the result; some carpels contract an adhesion with one another, and form a compound fruit; finally, the calyx adheres to the sides of the ovary, and then seems as if it grew from the apex of it. Irregularity in flowers and fruit is also in many cases produced by the unequal manner in which adhesion takes place between similar parts: of the calyx, two of the sepals adhere into one parcel, and three into another, the result of which is a two-lipped calyx; the same thing occurs in the corolla and elsewhere.

ADHESION. In Physics, a term used to denote the force with which different bodies remain attached to each other, when they are brought into contact. The adhesion of solid bodies is exemplified in the force required to separate two pieces of glass or marble whose polished surfaces have been brought into contact. The elevation of water above its level in capillary tubes, or between two plates of glass very nearly in contact, shows the adhesion of a fluid to a solid body; and an instance of the adhesion of two liquids is obtained by covering a plate of glass with oil, and bringing it into contact with the surface of water; a very sensible force is required to raise it perpendicularly from the water.

The adhesion of the polished surfaces of solid bodies is proportional to the extent of the surface, or to the number of points brought into contact. It was formerly believed that the resistance to separation in this case arises solely from the pressure of the atmosphere; but the difference of its amount in different substances proves this opinion to be erroneous; besides, it is found to be the same in a vacuum. [CAPILLARY ATTRACTION.]

Adiantum (Gr. ἀδίαντος, dry). A genus of thin-leaved ferns, having their fructification in short marginal lines attached to the recurved portion. The leaflets are usually wedge-shaped and placed upon slender black shining petioles. *A. Capillus-veneris* was formerly employed in the manufacture of syrup of capillaire; it is slightly tonic and fragrant.

Adiaphorites (Gr. ἀδιάφορος, indifferent). A name given to Melancthon, and the party that agreed with him, in submitting, in things indifferent, to an imperial edict. The controversy which gave rise to this name had its origin in the imposition by Charles V., in 1548, of an edict styled the Interim, because it proposed to accommodate for a time the differences of the Papists and Protestants, until the whole matter

ADIPIC ACID

could be set at rest by the authority of a council. In the debate which followed there were two principal questions: first, whether it is lawful to yield to the enemies of truth, even in matters which are not of themselves essential; and, secondly, whether, granting the affirmative, the points in which the Interim required compliance, and in which Melancthon yielded it, are properly indifferent. Those points related chiefly to the doctrine of justification by faith, in which Luther and his genuine followers went to a great extreme; while Melancthon, although ostensibly the head of the Lutheran church, after the death of the great Reformer, adopted much more moderate views. Out of this controversy a great variety of other debates were engendered, and from these quarrels many schisms and divisions among Protestants derived their origin.

Adipic Acid. A solid fat resulting from the action of nitric acid on various oily matters.

Adipic Ether. A compound of adipic acid and ether. Its odour is that of rennet apples.

Adipocere (Lat. *adeps* and *cera*, *fat* and *wax*). A fatty substance produced by the decomposition of the flesh of animals in moist situations, or under water, resembling, in some of its properties, a mixture of fat and wax.

Adipose (Lat. *adeps*, *fat*). Unctuous, or containing fat. Adipose membrane is the cellular membrane in which fat is deposited.

Adit. In Mining, a level or tunnel driven either on a vein or bed, or through barren rock, nearly horizontal, but rising slightly as it proceeds, and always sloping sufficiently to enable water to run along it from the furthest point in the interior to the adit mouth. The principal drainage of every mine is carried on by the adit. In the early works of a mine, an adit of moderate length is preferred, so that the expense shall not be inordinately great. As the mine becomes more important, it is often worth while to drive another deeper adit through a much greater distance of rock, rather than lift the water ten, twenty, or thirty fathoms. This is a practical matter of great importance, depending on the quantity of water to be raised, and the probable cost of driving the adit, as well as on the prospects of the mine.

Adits are often made subservient to discovery in a mine, the course selected being such as shall cross the greatest possible number of lodes, and those believed to be most important. It thus becomes what is called a *cross cut*.

Sometimes the adit is driven upon a cross course or vein at right angles to the general direction of the right running veins.

In coal mining, where the beds are nearly level, the selection of an adit, if one be required and can be conveniently constructed, has little or nothing to do with discovery. In Cornwall and elsewhere a few great adits connect several mines, and are many miles in length.

Adjacent Angle. In Geometry, an angle immediately contiguous to another, so that one side and the vertex are common to both angles. The term is more particularly used when the

ADJUTANT-GENERAL

two angles, besides having a common side, have their other sides in the same straight line. In this case, the adjacent angle is the same as the supplemental angle.

Adjective. In Grammar, that part of speech, denoting quality, which is annexed to nouns substantive to define more accurately the conceptions intended to be denoted by them. [GRAMMAR.]

Adjective Colours. Colours which require to be fixed by some base or mordant, in order to be applied as permanent dye-stuffs.

Adjournment (Fr. *ajournement*). In Parliamentary language, means a postponement of the sittings or proceedings of either House of Parliament, and differs from prorogation in this, that the latter is an act of royal authority, whereas the power of adjournment is vested in each house respectively, no definite limits being prescribed to it by the constitution. [PROROGATION.]

Adjudication (Lat. *adjudicatio*). In Bankruptcy Law is the act of the Court declaring the person to be bankrupt.

Adjudication in Implement. In Scotch Law, a form of adjudication for the completion of defective titles to landed property.

Adjudication, Special. In Scotch Law, a mode of dealing with part of a debtor's lands, in the power of the lords of session.

Adjustment. In Marine Insurance, the settlement of a loss incurred by the insured.

Adjutage (Lat. *adjuto*). A term applied, by modern authors upon Hydraulics, to express the additional tubes added to the sides of an orifice in a vessel, for the purpose of obviating the resistance to the discharge by the contraction of the fluid vein. This resistance may become as great as 0.46 of the whole theoretical delivery of an orifice made in the bottom of a large sluice, and it is therefore a matter of great delicacy to determine the form of adjutage best fitted to obviate it. Venturi has made the most elaborate experiments upon the form of these tubes; and he arrived at the conclusion that it is best to make them of a divergent form, in which the dimensions of the orifice of delivery were about 0.0338, and the orifice at the entry 0.0406; the angle of the sides of the external tube was 50.6, and the length nine times the diameter of the effective opening. Venturi ascertained that the result of the application of these divergent adjutages was to increase the discharge by the orifice to about 1.46 times the theoretical discharge, and 2.4 times the discharge which would have taken place had the orifice been in a thin plate.

Adjutant. An officer appointed to each battalion of a regiment. His duty generally is to assist the commanding officer.

Adjutant-General. The chief staff officer of the army. His department is charged with the execution of all orders relating to the recruiting and equipment of the troops, their strength, instruction, and efficiency. There are also assistant and deputy-assistant adjutant-generals of divisions and districts.

Adjutant-General of the Jesuits. A title given to certain fathers who resided with the general of the order.

Adjuvant (Lat. *adjuvare, to help*). In Medicine, a substance which assists and promotes the operation of others.

Administration. In Law, if a person die intestate as to his personality, letters of administration are granted by the ordinary (now by the Probate Court) to such person as is pointed out by the statutes 31 Edw. III. and 21 Hen. VIII. These empower the ordinary to grant these letters to the widow, if there be one, or next of kin, at his discretion. Of persons equally near in degree, the ordinary may grant to which he please. If none of the kindred take out administration, a creditor may do it. When the will

made without the nomination of any executor, the ordinary grants administration cum testamento annexo. Where a person dies intestate, his personal property descends (subject to his debts) as directed by the Statute of Distributions, 22 & 23 Ch. II. c. 10, explained by 29 Ch. II. c. 30. One-third goes to the widow; the residue in equal proportions to the children, or, if they are dead, to their representatives, i. e. their lineal descendants. If there are none of these, then the widow takes a moiety, and the next of kin in equal degree, and their representatives, take the other; if there be no widow, they take the whole. But of representatives, none are admitted among collaterals, farther than the children of the intestate's brothers and sisters. The order of nearness of kin, with reference to the distribution of intestates' estates, is thus arranged according to the rules of the civil law—children, parents, brothers, grandfathers, uncles or nephews (and the females of each class respectively), and, lastly, cousins.

ADMINISTRATION. In Politics, in its general sense means the conduct or management of any affair; but in this country the term is usually applied to the management of the public or national affairs by the government, which is thence called *the Administration*.

Admiral (a word of doubtful origin). A great naval officer, who has the same power and authority over the maritime forces of a state that a general has over its land forces; and who also tries, or appoints officers to try, maritime cases. There are three ranks of Admirals, the Admiral (or full Admiral), Vice Admiral, and Rear Admiral. Each of these again has three gradations, of red, white, and blue, the colours of the flags they bear. The Admiral carries his flag at the main, the Vice at the fore, and the Rear at the mizen mast.

ADMIRAL, Lord High. The ninth great officer of state in England. The office has been usually given, at least since the reign of Henry IV., to some of the king's youngest sons, near kinsmen, or of the higher nobility. Since the reign of Charles II. it has been, with occasional exceptions, always in commission, and the commissioners are styled 'Lords of the Admiralty.' It was held by the late sovereign

William IV., when Duke of Clarence, from 1827 to the following year.

Admiralty. The Board of Commissioners for executing the Office of Lord High Admiral, and having authority over naval affairs generally.

ADMIRALTY, Court of. In Law, is a court of record, of which the proceedings are principally carried on according to the course of the civil law; although, as the judge may have in some cases the assistance of a jury, it has also a resemblance to the courts of common law. It has jurisdiction principally for the determination of private injuries to private rights arising at sea, or intimately connected with maritime subjects; and in most cases to which its authority extends it has concurrent jurisdiction, either with the common law courts, or those of equity. Suits may be instituted in this court for assault and battery at sea; for collision of ships; for the restitution of goods piratically taken not under colour of war. It has also an equitable jurisdiction between part owners of a ship. It adjudicates in suits for mariners' wages, and for pilotage. It has a peculiar jurisdiction in cases of bottomry bonds, and other deeds in the nature of a mortgage of the ship; having an exclusive power to grant warrants to arrest the ship itself. It has also jurisdiction in cases of salvage, and incidentally of wreck. See the Act 24 Vict. c. 10 (1861) to extend the jurisdiction and amend the practice of this court.

The prize court, which decides prize causes in time of war, is a separate tribunal, although usually presided over by the same judge as that of admiralty.

Admission (Lat. *admissio*). In Law, that which a party, in pleading, admits against himself, and thereby relieves the adversary from the necessity of proving. Such an admission, technically styled 'on the record,' may be either actual or constructive. It is common to speak also of admissions made by agreement between the parties.

Admonition (Lat. *admonitio*). The first step of Ecclesiastical censure, which always precedes excommunication. (Hook, *Church Dictionary*, s. v.)

Admonitionists. Certain Puritans, who in 1571 sent an 'admonition' to the Parliament, condemning everything in the Church of England which was not in agreement with the doctrine and practice of Geneva. (Hook, *Church Dictionary*, s. v.)

Adnate (Lat. *adnatus*, from *adnascor, I grow to anything*). An organ is said to be adnate when it grows to the face of another, and not to its apex, in which latter case it would be innate. The term is chiefly employed in botany in speaking of anthers.

Adonic (Gr. *Ἀδωνίς*). A verse consisting of a dactyl and a spondee, as in the last line of every Sapphic Stanza, as, *viscere montes*, Horace, *Od. i. 2*.

Adonis. (Gr.) In Mythology, a beautiful youth beloved by Aphrodite or Venus, and slain by a wild boar, or, according to other versions,

ADOPTER

by Apollo or Artemis. Adonis is the father of Priapus, and is identified with the Eastern Thammuz. A river of the same name in Phœnicia was supposed yearly to express its sympathy for his death by changing the colour of its waters to red. (Milton, *Paradise Lost*, i. 416.)

Adopter. A vessel with two necks placed between a retort and a receiver, serving to increase the length of the neck of the former.

Adoptians. In Ecclesiastical History, the name given to the followers of Elipand, Archbishop of Toledo, and Felix, Bishop of Urgel in Spain, who maintained, that, as to his humanity, Christ was only the adopted Son of the Father. (Milman, *History of Latin Christianity*, book v. ch. i.)

Adoption (Lat. *adoptio*). In the Civil Law, signifies the admission of a stranger to the rights and privileges of a son. Adoption was a common custom among the Romans, by whose law a relation, nearly resembling that of master and slave, was constituted between father and son; so that a child, adopted from one family into another, passed, in effect, from the power of his parent to that of his adopter. Adoption is said, in Justinian's Institutes, to be of two sorts: the one, also called arrogation, where a person, independent of parental control, is adopted into a family by virtue of an imperial rescript; the other, where, by the authority of a magistrate, a child passes from one family to another. But unless the adopter possessed a certain right by blood over the person adopted (as a grandfather), the parental power of the father was not extinguished. Adoption exists in the jurisprudence of various countries, where derived from the civil law; as in the German states and in France. In the latter country, the person adopting must be one having neither children nor other legitimate descendants.

Adoration (Lat. *adoratio*). This word, derived by many from the expression *ad os* (to carry the hand to the mouth), was applied originally to religious ceremonies, in which the worshipper kissed his hand and then held it out towards the statue of the god whom he was reverencing. It was afterwards used to signify prostration before kings, a custom apparently Persian in its origin. The attempt of Alexander the Great to exact it from his officers caused great dissatisfaction. It was introduced into the Roman court by Diocletian, and the practice was afterwards regulated by an elaborate ceremonial. (Gibbon, *Roman Empire*, ch. liii.)

Also a term used for a mode of electing a pope. The cardinals rush hastily, as if by an internal impulse, and proclaim some one pope.

Addressed. In Botany, when one part lies close to another throughout its length, as hairs to the surface of a leaf. The same as APRESSED.

Adragant. Gum Tragacanth.

Adrianople Red. A term applied by dyers

ADULTERY

to the red obtained from madder: it is also called *Turkey red*.

Adrift. Not fastened; as a ship that has parted from her anchor, a boat that has broke from her ship, a gun from the ship's side, &c.

Adularia. A transparent or translucent variety of Orthoclase or potash-felspar, which is found in colourless crystals, with a strong vitreous lustre, at St. Gothard in Switzerland; the finest specimens being procured from one of the highest peaks, called Adula: whence the name Adularia. It is also met with in the United Kingdom in the slate of Tintagel in Cornwall; on Snowdon with quartz; in the Isle of Arran in Buteshire; and on Slieve Corra, one of the Mourne mountains, in Ireland. It is sometimes used as a glaze for the finer kinds of pottery.

Adulteration (Lat. *adulteratio*). The partial substitution of inferior, cheaper, useless, or other undesirable material, for professedly genuine merchantable articles. Individual greed has always been an incentive to the practice of adulteration by traders, but of late years the public demand for cheap goods, and the competitive supply occasioned by it, has greatly contributed to increase this practice. The adulteration of tobacco, beer, tea, coffee, bread, and a few other articles of general consumption, has for some time been punishable by law. But although by the aid of the chemist and microscopist, it is generally an easy matter to detect adulteration, it is difficult to prove by whom the sophistication has been practised; convictions, consequently, have seldom been effected. The same obstacle to successful legislation in the matter has also been one of the chief causes of the failure of the 'act for preventing the adulteration of articles of food and drink,' which was passed in 1860: moreover adulteration is still allowed, provided the sophisticated material be neither injurious to health, nor stamped or warranted 'genuine.'

Adulterine. In Law, properly the children begotten by adultery of the father or mother, who were excepted by various laws and usages from that legitimization of natural children which in the civil law takes place by subsequent marriage.

Adulterine Guilds. Persons acting as a trading corporation without a charter, and paying a fine annually for permission to exercise their usurped privileges. (Smith, *Wealth of Nations*, b. i. c. 10.)

Adultery (Lat. *adulterium*, a word of very uncertain derivation). The sin of incontinence committed by a married person: adultery between two married persons is termed *double* by some jurists. By the law of Moses, adultery was punished by death, Lev. xx. 10, Deut. xxii. 22; and passages in Proverbs (c. vi.) and Ezekiel (xvi. 38, 40) prove that the law was observed in this respect down to the overthrow of the Jewish monarchy, as we know it to have been in the time of our Saviour. The mode of punishment was by stoning; but it is observable that this mode is not ordained in Deuter-

onemy as it is for various other offences. The test or ordeal of adultery is detailed in Numbers v. 11. 81. Under the Grecian and Roman republics adultery was variously treated; but the celebrated Lex Julia de Adulterio, under Augustus, punished it with banishment (*deportatio vel relegatio*).—Tacit. lib. ii. *Annal.* It was not until the reign of Constantine, when some tincture of Judaism had been introduced into the state, along with the establishment of Christianity, that the punishment of death was formally enacted for it. This penalty was again mitigated under Leo and Marcian; and by the laws of Justinian the adulterer was punishable with death, the adulteress with flagellation, imprisonment, &c. But about the same period the gradual increase of episcopal authority in civil cases, seems to have drawn crimes of incontinence almost wholly within the cognisance of the ecclesiastical courts; and the canons contain a variety of directions on the subject of adultery. On the other hand, the jurisprudence of the Northern nations, which visited this as well as other crimes of freemen with very little severity, as mere offences against individuals, reduced the penalty in most of the Western kingdoms to a mere pecuniary one, sometimes attended with public disgrace or corporal punishment. Such penalties fell rapidly into disuse; and in the sixteenth century we find it observed by a French civilian (quoted by Thuanus), that 'it was never heard that anybody had been punished for adultery in France.' This observation is quoted by the historian when relating an event which created great sensation at the time, namely the capital punishment at Orleans of two offenders by St. Cyr, the governor, a rigid Calvinist. The protestants of that sect, in France as well as in Scotland and England, made it their endeavour to introduce primitive severity of manners by severity of punishment. De Thou appears also to have made some efforts toward putting in force the laws against adultery: but from the time of the religious wars, penal cognisance of adultery may be said to have nearly ceased in France, although, by various *arrêts* (1637, 1701, &c.), besides the civil consequences of an action of adultery by husband against wife, the latter might be condemned to seclusion in a house of correction for two years, or more; and the punishment of imprisonment still subsists, and has been in some recent cases inflicted. In Geneva, Strasburg, and other places where the reformed religion prevailed, a temporary strictness of law was introduced about the same period, but with little permanent effect. In England, by the old common law, mutilation was the punishment of this as well as other offences; but under the Plantagenets it became matter of ecclesiastical cognisance (except so far as civil consequences were concerned), and visited only by the spiritual censure of the church. 'The rules of the canon law,' says a recent writer, 'have manifested an indulgence towards this offence which is chiefly to be accounted for by reference to

the constrained celibacy of its early compilers.' But in 1660 the Puritans, under Cromwell, succeeded in obtaining an ordinance by which adultery, as well as simple fornication, was made felony, without benefit of clergy; an absurd decree, which was soon repealed. [For the civil consequences of Adultery, see DIVORCE; MARRIAGE, LAW OF.]

Advent (Lat. *adventus*). The holy season, comprising four Sundays before Christmas. It begins on St. Andrew's day, the 30th of November, or on the Sunday next before or after it, according to the day of the week on which the 25th of December falls.

Adventitious (Lat. *adventitius*, *foreign* or *strange*; hence, *extraordinary*). In Botany, when anything appears out of the ordinary course of nature: if a bud appears where buds do not usually appear, it is adventitious. This term must not be confounded with abnormal, which is used when anything is *constructed* out of the ordinary course.

Adverb. A word annexed to an adjective or verb, to define more closely the modifications of the quality or action denoted. [GRAMMAR.]

Adversa (Lat.). A medallic term, applied to two heads facing each other.

Adversaria (Lat.). In Philology, a classical title used for books of miscellaneous remarks or discussions.

Adverse (Lat. *ad*, *to*, and *verto*, *I turn*). In Botany, leaves are so called when they present their under-surface to the sun.

Advertisement (Lat. *adverto*, *I attend to*). In its general sense, means any information as to any fact or circumstance. But it is more particularly used to designate notices made by competent authority in the daily papers, and otherwise, of events of local or general interest, as the publication of new books, sales of estates and produce, meetings of creditors, formation and dissolution of partnerships, &c. Such notices, when inserted in the *Gazette*, or in newspapers and literary works published in numbers, formerly paid a duty, which was abolished by an act passed in 1853.

Advocate (Lat. *advocatus*, *he who is called in to plead in a court of law the cause of another*). The original pleaders of causes at Rome were the patricians, who defended their clients gratuitously; but even before the downfall of the republic, the class had degenerated into a profession, (its members receiving rewards for their services,) although still among the most honourable of employments. But from the original gratuitous character of advocates arose the peculiar custom by which, among ourselves, the fees of barristers are still regarded as honorary, and cannot be recovered at law. In the later ages of the empire the *advocati* appear to have formed a distinct class from the *jurisconsulti*, or chamber-counsel, and to have much declined in reputation. In France the *avocats*, or counsel, form a separate order, of which each member is attached to a particular local court. The Lord Advocate, in Scotland, is a public officer, who prosecutes

crimes before the court of judicatory. The Queen's Advocate, in England, conducts the business of the crown in the Ecclesiastical and Admiralty Courts, and has precedence of the Attorney- and Solicitor-General. The Judge-Advocate acts for the prosecution in court-martial, and is the military law adviser of the crown.

Advocates, Faculty of. The bar of Scotland in Edinburgh is so called.

Advowson (Lat. *advocatio, a calling*). Properly the relation in which a patron (*advocatus*) stands towards the living to which he presents, i. e. the patronage of a church. The earliest provision for divine worship, in England and in other countries, was derived from the offerings of the laity, which were distributed by the bishop of each diocese among his clergy, whom he sent from place to place to preach and administer the sacraments. By degrees he was enabled, by the bequests of the faithful, and the customary offering of tithes, to subdivide his diocese, or *parochia*, as it was originally called, into various districts, and to build churches and establish permanent ministers in each. At the same time it became a common practice among the nobles to build and endow churches for the benefit of themselves and their own dependants; in which case they were allowed to present to the benefice, subject to the licensing power of the bishop and the canons of the church. Advowsons, in legal phraseology, are either appendant, where immemorially annexed to a manor; or in gross, where they form separate subjects of property. If the patron of a rectory fails to present within six months after the vacancy happens, the right falls to the bishop, and by similar neglect on his part, to the archbishop, and thence to the king. The presentation is by letter to the bishop; institution, by an instrument registered in the bishop's court; and induction, which completes the incumbent's title, is performed by the archdeacon.

Ady. A palm tree growing on the Island of Thoné, on the coast of Malabar. The aromatic kernel of its fruit contains an oil from which a kind of butter is made.

Adytum (Gr. *ἄδυτον*, from *ἀ*, neg., and *δύω, to enter*). The shrine, or holy of holies, in temples where oracles were given or where the worship was connected with mysteries. To this shrine only priests had access. The *seios* of the Egyptian temples seems to have answered to the adytum of the Latins. The Greeks introduced into their religious edifices a treasure-chamber, or *opisthodomos*, which had its entrance in the back-front of the temple. The adytum of the small temple of Pompeii is one of the best preserved examples of these chambers. It is raised some steps above the level of the body of the temple and is without light.

Adze. A carpenter's tool, used as an axe, but of which the blade is made curved, and with its edge, not like the axe, parallel to the handle, but placed at right angles to it. The

adze is used to dress timbers in such situations as the plane will not reach with any advantage, especially in dressing the posts, &c., in ship building, and in floors, &c.

Adchalotarch (Gr. *αἰχμαλωτάρχης*, taken with the spear, and *ἔρχω, I rule*). The title of the governor of the captive Jews residing in Chaldee, Assyria, and the adjacent countries. He was called by the Jews themselves *Rosch-galuth*, chief of the captivity.

Ædelforsite. A neutral silicate of lime, occurring massive, and fibrous or feathery, of a white or greyish colour, at Ædelfors in Sweden. The name Ædelforsite has also been given by Retzius and Nicol to the red zeolite of Ædelfors. [REZZIUS.]

Ædes. The Latin term for a dwelling of any kind, but more especially applied to large town dwellings, or palaces, in contradistinction to *domus*, a small private dwelling, or to *villa*, a country house. The small temples dedicated to the service of the gods by the piety of private individuals, and which were not consecrated by the augurs, were also called *ædes*, and were so far from being considered sacred edifices that they were frequently devoted to profane uses, as in the case of the *Ædes Saturnii*, which was made to serve as the *Ærarium*. In the later periods of the Roman Empire this distinction between the *ædes* and the *templum* was lost sight of; and at all times the form and distribution of the two classes of monuments were analogous.

Ædicula (Lat). In the singular, a room; in the plural, a small house; at other times, a small temple. In the latter sense it is applied to the shrines for the reception of the statues of the deity, as for instance, in the *ædicula* of the Pantheon of Rome, or to the domestic shrines in which were placed the statues of the Lares, Penates, or the protecting divinities of the house or city, ranged round the courts of the *ædes*.

Ædile. The title of certain Roman magistrates, so called from their care of buildings (*ædes*). They were divided into two classes, distinguished by the epithets *plebeian* and *cureule*. The two plebeian *ædiles* were, as their name imports, elected from the commonalty (*plebs*), and were subordinate to the tribunes of the commons, having jurisdiction over lesser causes, submitted to them by those magistrates. The two *cureule ædiles*, so called from their privilege of giving judgment on ivory seats (*selle curules*), were originally elected from the patricians, but afterwards from both plebeians and patricians promiscuously. This magistracy was one of the most dignified in the state, and was allowed the use of the robe of honour (*toga prætexta*), and a certain precedence in the senate. The peculiar office of the *ædiles* was the superintendence of public works, markets, &c., in the city. They had also, particularly the *cureule ædiles*, to exhibit public games, which they often did at a vast expense, in order to court popularity. Julius Cæsar added two plebeian *ædiles*, called *Cæroal*, to inspect the public stores of provisions. (Smith, *Dictionary of*

Greek and Roman Antiquities, s.v. For the doubtful points connected with the origin of these offices, see Sir G. C. Lewis, *On the Credibility of Early Roman History*, ch. xii. xiii.)

Ægicereæ (Gr. αἴ, goat, κέρας, horn). A division of Myrsinaceous plants, the type of which is the genus *Ægiceras*. It is distinguished by the absence of albumen; the species grow in maritime swamps in tropical countries, and have the embryo germinating within the pericarp, after the manner of mangroves.

Ægilops (Gr. αἴ, a goat, and ὤψ, an eye). A sore in the inner angle of the eye, frequently terminating in fistula lachrymalis. Goats were supposed to be very subject to this affection.

Ægilops. A genus of grasses, which there is reason to suppose may have been once the mother of wheat.

Ægirine. A black or greenish variety of Pyroxene, allied to Arfvedsonite, found at Brevig, in Norway.

Ægis (Gr. αἰς). The mythological shield of Zeus (or Jupiter), which was covered with the skin of the goat Amalthea, and given by him to Athena (or Minerva), who, by fixing on it the head of Medusa, gave it the power of petrifying all persons who looked at it. In some works of art it is represented as a metal breastpiece, wrought in scales.

Ægle (Gr. Αἴγλη, one of the Hesperides). A genus of the orange family, containing the bluel fruit, *Æ. Marmelos*, which is of exquisite flavour. The rind furnishes a yellow dye, and in the unripe state possesses astringent properties, on which account it is used in India in cases of dysentery. The genus is known from that of the orange by the stamens being separate, not united in bundles.

Æneid. The epic poem of Virgil, relating the wanderings of Æneas after the capture of Troy, and his settlement in Italy.

Æoliople (Lat. Æolus, the god of the winds, and pila, a ball). An hydraulic instrument, contrived for the purpose of exhibiting the convertibility of water into steam. It consists of a hollow ball of metal, having a slender neck or pipe, with a very small orifice inserted into it. The ball, having been filled with water, is placed over the fire, and the heat gradually converts the water into vapour, which rushes out of the pipe with great violence till the whole is discharged. The experiment is not unattended by danger, for should the small orifice by any accident be stopped, the steam would burst the ball. The æoliople was known to the ancients, being mentioned by Vitruvius. Descartes and others have used it to account for the natural cause and production of the wind; hence its name, Æoliople. The æoliople is sometimes filled with alcohol, and the jet of its vapour being inflamed, it serves the purpose of a blowpipe.

Æolus. In Mythology, the god of the winds, who was fabled by the early poets to have his seat in the floating island of Æolia; but the Latin and later Greek poets placed him in the Lipari isles. Here the winds were pent

up in vast caves, and let loose or restrained by Æolus at the bidding of Jupiter. See a fine passage in Virgil, *Æneid*, i. 62.

Æolus' Harp, or **Æolian Harp**. An instrument, which produces a pleasing combination of sounds by the action of the wind. Its construction is very simple, consisting of merely a number of catgut or wire strings, stretched in parallel lines over a box of thin deal, with sounding holes cut in the top. The strings being tuned in unison, the effect is produced by placing the instrument in a current of air. The invention of the Æolian harp is generally given to Kircher, by whom it was first described.

Æon. [Gnostics.]

Æpyornis (αἰψός, high, and ὄρνις, bird). A colossal genus of cursorial birds, which has left its remains in pliocene strata in Madagascar. One of the fossil eggs of this species has been estimated to contain as much as six ostrich eggs, or 148 hens' eggs.

Æra, or **Æra** (Lat.). In Chronology, the term æra denotes the account of time reckoned from some particular date or epoch, chosen for the commencement of the æra.—Thus the Christian æra began at the birth of Christ; the Mohammedan æra at the flight of Mohammed from Mecca to Medina; the æra of Diocletian at the coronation of that emperor, &c.; and the period of the occurrence of any event is ascertained by reckoning from one or other of these epochs. When, for example, it is said, that Queen Victoria ascended the throne of Great Britain in 1837, it is meant that this event took place in the 1837th year of the Christian æra, or of that æra which began with the birth of Christ. It is plain that the epoch, or point of time selected for the commencement of an æra, is necessarily arbitrary; and different nations have adopted different epochs coincident with some important event in their civil or religious history. Some chronologers reckon from the creation of the world; and this event, were its date well ascertained, would be the best epoch that could be selected. The Greeks used to reckon by the æra of the Olympiad [which see] which began at the summer solstice, anno 776 n. c. The Romans reckoned from the building of the city, generally held to be April 24th, n. c. 753. The Julian æra dates from the reformation of the calendar by Julius Cæsar, n. c. 45. All Christian nations now adopt for their æra the birth of Christ, supposed to have taken place in the middle of the fourth year of the 194th Olympiad, and the 753rd year of the building of Rome. The æra of most Mohammedan nations is that of the Hegira, or flight of Mohammed to Medina, corresponding with July 16th, A. D. 622. The æra of Sulwanah, in common use in a great part of India, corresponds to A. D. 78. The æra of Yezdegird, used in Persia, began June 16th, A. D. 632.

Suljoined are the names of some of the principal æras, with the year of the Christian æra in which they began, and the abbreviations by which they are commonly distinguished.

ÆRARIAN

Commenced | Abbreviations

Year of the World :—	
Constantinopolitan account	5509 A.M. Const.
Alexandrian account	5492 A.M. Alex.
Jewish account	3760 A.M.
Æra of Nabonassar	747 Ær. Nab.
Olympiads	776 Olymp.
Year of Rome	753 A. U. C.
Julian Æra	45 Jul. Ær.
Christian Æra	— A. D.
Æra of Sulwanah	A. D. 78 Sacra.
Æra of Diocletian	284 Ær. Dioc.
The Hegira	622 A. H.
Æra of Yazdegird	632 A. Pers.

The term *æra* is frequently used as synonymous with *epoch*, but it would seem incorrectly. (Scaliger, *De Emendatione Temporum*.)

Ærarian. The term applied to a Roman citizen who had been degraded to the lowest rank compatible with personal freedom, and who had become, therefore, a mere payer of money (*as, æris*) for the support of the state. He still paid taxes, but enjoyed no privileges, and could not serve in the army, or, consequently, participate in the distribution of land granted to such classes as did.

Ærarium (Lat.) The public treasury of the Roman plebs, the care of which was vested in the quaestors. After the fall of the republic the ærarium was kept distinct from the treasury of the emperor, which was called *fiscus*. The ærarium sanctius, or more sacred treasury, was appointed to provide for cases of extreme emergency, and might not be opened on other occasions.

Ærated Waters. Waters charged with gas under pressure. The gas is usually carbonic acid, derived from bicarbonate of soda or from carbonate of lime by the action of a dilute acid. Ærated waters commonly contain dissolved salts, and are then termed *mineral waters*. All natural water is more or less ærated, and the flat mawkish taste of recently boiled water is due to the absence of dissolved carbonic acid and of atmospheric air. The term is, however, commonly restricted to water artificially charged with gas, and which on exposure to the ordinary pressure gives off a part of its gas with effervescence. Wine and beer are rendered 'sparkling,' or effervescent, by internal decomposition after bottling.

Ærial (Gr. *ἀήρ*, *air*). In Painting, a term applied to the diminishing intensity of colour on objects receding from the eye. Ærial perspective is the relative apparent recession of objects from the foreground, owing to the quantity of air interposed between them and the spectator, and must accompany the recession of the perspective lines.

The degree of ærial gradation required depends upon climate and the time of day, the effects varying with the degrees of moisture in the atmosphere. It is scarcely indicated in the backgrounds of the early Italian painters.

Ærial Acid. [CARBONIC ACID.]

Ærial Images. In Optics, the name given to images of objects produced by reflection or

AERO-DYNAMICS

refraction when they appear suspended in the air. For example, a spectator standing before a concave mirror, at a somewhat greater distance from it than its radius of curvature, sees an inverted image of himself, hanging as it were between him and the mirror. For examples of ærial images produced by refraction, see *FATA MORGANA*; *MIRAGE*.

Ærial Plants, or Aerophytes (Gr. *ἀήρ*, and *φυτόν*, *a plant*). Plants which grow in air only, as distinguished from terrestrial plants or those which grow in earth. The epiphytal orchids, and many lichens, are ærial plants, deriving sustenance from atmospheric moisture. They are to be distinguished from parasites, like mistletoe, which feed on and not merely grow on trees, &c.

Aëro-dynamics (Gr. *ἀήρ*, and *δύναμις*, *power*). The science which treats of the motion of the air, and of the mechanical effects of air in motion. This is a branch of experimental science, and there are two ways in which it may be investigated. The first consists in ascertaining the effects which air moving with a certain velocity, that is, wind, produces on a body against which it strikes; and the second, in measuring the resistance which air at rest offers to a solid body passing rapidly through it. The problem is exactly the same, whether the body is considered as moving against the air at rest, or the air is supposed to move against the body with the same velocity.

When a solid body is moved out of its position, the space which it occupied is not filled with air instantaneously, but only after a sensible, though very short time. Theory, confirmed to a certain degree by experience, shows that air, under the ordinary atmospheric pressure, rushes into a vacuum with a velocity of between 1300 and 1400 feet in a second of time.

Now, conceive a body, for example a cannon ball, to be moving rapidly through the air, but with a less velocity than 1300 feet per second. The air in front of the ball will remain in its natural state, because the condensation produced every instant by the contact of the ball, is propagated more quickly than the ball moves (the velocity of the propagation being equal to that with which air enters a vacuum). But there is a certain space behind the ball in which the air has not entirely recovered its equilibrium, but remains more or less rarefied, the ball having passed through it in less time than is required for the surrounding air entirely to fill it. In addition, therefore, to the resistance which arises from the communication of motion to the particles of air, an effect proportional to the square of the velocity, there is a pressure on the front part of the ball, not counterbalanced from behind; in consequence of which, we may infer that the resistance will increase in a quicker ratio, and this deduction is confirmed by practical experience.

The resistance of the air on the motion of projectiles was first examined experimentally by M. Robins (see his *Principles of Gunnery*),

AEROLITE

and afterwards by Dr. Hutton, of Woolwich (see his *Tracts*, vol. i. ff., and *Math. Dictionary*). [PHOBOTILES; WIND.]

Ærolite (Gr. *ἀήρ*, air, and *λίθος*, a stone). The origin of these singular substances is involved in the greatest mystery. Some philosophers, among whom is Laplace, the illustrious author of the *Mécanique Céleste*, suppose them to be ejected from volcanos in the moon; others suppose them to exist ready formed in the celestial space, circulating about the sun with great velocity, like planets, and falling to the earth when its attraction upon them preponderates; others regard them as fragments of rocks which have been propelled by terrestrial volcanos to an immense height above the limits of the atmosphere, and again descend after having described several revolutions about the earth.

On examining and comparing ærolites, the first circumstance that strikes us as remarkable is their resemblance to one another in their composition, whatever be their form or magnitude. Their exterior surface is black, as if they had been exposed to the heat of a furnace. Internally they are of a greyish white. Their specific gravity varies between 3.362 and 4.281. Their chemical analysis gives, in almost every instance, the same substances, combined in nearly the same proportions. They are composed of silica, magnesia, sulphur, iron in the metallic state, nickel, and some traces of chrome. Sometimes they are of a spongy or cellular texture, the cavities being filled with a stony substance. They have occasionally been found without nickel. These common and constant characters indicate a common origin, and their composition renders it probable that it is to be sought elsewhere than in the earth. Iron is scarcely ever found (if, indeed, at all) in the metallic state in terrestrial substances; volcanic matter contains it only in the state of oxide. Nickel and chromium are also rare, and not found on the surface of the earth.

The fall of the ærolites is accompanied by meteors, named bolides, or fire balls. They are, in fact, inflamed globes, which appear instantaneously in the atmosphere, and move through it with extreme velocity, sometimes even equal to that of the earth in its orbit. The direction of their motion is inclined to the horizon. After shining with great splendour for a few instants, they explode with a loud noise, and often at a great height, thirty or forty miles above the surface of the earth. They do not affect any peculiar direction with respect to the motion of the earth, but seem to come from all points of the heavens indifferently.

With regard to the hypothesis which explains the origin of the ærolites, by supposing them to be propelled from lunar volcanos, it may be remarked that no improbable amount of mechanical force would be required. As there is no atmosphere about the moon sufficient to offer a sensible resistance to the motion of a solid body, the force required is only that

AEROSTATION

which would be sufficient to overcome the moon's attraction, which is found by calculation to be about four times the force with which a ball is expelled from a cannon with the ordinary charge of gunpowder. A body projected with a velocity of about 7770 feet per second from the lunar surface would be detached from the moon, and be brought to the earth by terrestrial gravitation. But philosophers seem now disposed to assign the ærolites a different origin. From the phenomena of comets there is reason to believe that portions of chaotic matter are dispersed in the planetary regions in detached parcels, or perhaps in considerable masses. The earth in describing its orbit may meet with such masses directly, or pass so near to them as to carry them along with it by virtue of its attraction. On plunging into the atmosphere with the velocity due to the height from which they have fallen, which is that of their distance from the earth when they begin to obey its attractive force, an enormous heat is evolved by the rapid and powerful condensation of the air; the matter becomes inflamed, and the ærolite is the product of the combustion. In the same manner shooting stars, and other igneous meteors of frequent occurrence, are explained. The chaotic matter may be entirely consumed long before it reaches the earth, in which case the appearance of the bolide will not be accompanied with the fall of an ærolite. [FIREBALLS; METEORITE.]

Philosophers were long inclined to disbelieve in the fall of stones through the atmosphere. The fact, however, is now placed beyond all doubt by numerous and well-authenticated instances which have occurred in almost all quarters of the world, even within the present century. A very complete list of the falls of stony or earthy matters, with the times and places of their occurrence, and the appearances they exhibited, is published in the *Edinburgh Philosophical Journal*, from a work by Chladni, in German, in which the whole subject of meteoric stones is ably and fully treated.

Ærology (Gr. *ἀήρ*, and *λόγος*, a discourse). The doctrine of air, generally applied to medical discussions respecting its salubrity.

Ærometer (Gr. *ἀήρ*, and *μέτρον*, a measure). An instrument for making the necessary corrections in pneumatic experiments, to ascertain the mean bulk of gases.

Æronautics (Gr. *ἀήρ*, and *ναυτικός*, of or belonging to ships). The art of sailing in and navigating the air. [BALLOON.]

Ærophytes (Gr. *ἀήρ*, and *φυτόν*, a plant). Plants which live exclusively in air; in distinction to hydrophytes, which live as constantly under water.

Ærostatics (Gr. *ἀήρ*, and *στατική*, (sc. *ἐπιστήμη*), the science which determines the properties of bodies at rest). A term sometimes used to denote the science which treats of the equilibrium of elastic fluids. [PNEUMATICS.]

Agrostation. Means simply the weighing of the air: but is sometimes employed in the same sense as æronautics.

ÆSCHYNITE

Æschynite (Gr. *αἰσχύν, disgrace*). A titanate of zirconia and cerium, found in Felspar, in the Ilmen range of mountains, near Miask in Siberia. It occurs in oblique rhombic prisms, terminated by four-sided pyramids, which are generally striated and imperfect. The crystals are nearly black and opaque, or inclining to brownish-yellow when translucent. The name was given by Berzelius, in allusion to the inability of chemists, at the time of the discovery of the mineral, to separate the titanic acid and zirconia which enter into its composition.

Æsculaceæ. A natural order of exogenous plants, consisting of the horse-chestnut, *Æsculus hippocastanum*, and other nearly allied species. They are all either shrubs or trees inhabiting temperate regions, and nearly corresponding with the horse-chestnut in the structure of the flowers. Their seeds contain starch mixed with the detergent matter called saponine, and their bark is in some cases bitter and astringent.

Æsculapius (Gr. *Ἀσκληπίδης*). In Mythology. He was the son of Apollo and the nymph Coronis. He was worshipped as the god of surgery and medicine; but the older poets, as Homer and Pindar, mention him only as a hero well skilled in these arts. The chief seat of his worship was Epidaurus, where he was represented as an old man, with a mantle and staff, round which a serpent is twined.

Æsculine. A peculiar substance contained in the bark of the horse-chestnut tree (*Æsculus hippocastanum*): it appears in the form of a white crystalline powder, and when dissolved in very minute quantities in water, communicates a blue opalescence to it.

Æsthetic (Gr. *αἰσθητικός, having the power of perception by means of the senses*). In the Fine Arts, that which derives the first principles in all the arts from the effect which certain combinations have on the mind, as connected with nature. The æsthetic quality of a work of art is that which is apprehended by the perceptions or feeling, irrespective of the understanding.

Æthna. A name applied by Fabricius to a genus of dragon-flies, characterised by having the wings expanded when at rest, and the divisions of the lip equal.

Æstivation (Lat. *æstivus, of or belonging to summer*). A figurative expression, employed to indicate the manner in which the parts of a flower are arranged before they unfold. Botanists speak of the æstivation of the calyx, of the corolla, and of the stamens.

Æstuary, or Estuary (Lat. *æstuarium*). In Geography, was anciently understood to be any creek, frith, or arm of the sea, in which the tide ebbs and flows (Plin. *Epist.* lib. ix. ep. 33); but it is now applied to designate those parts of the channels of certain rivers contiguous to the sea, in which the water is either salt or brackish, and in which the ebb and flow of the sea is distinctly perceptible, and there is little or no current.

Æsymnetes (Gr. *ἀσύμνηται*). A class of

ÆTHUSA

Greek tyrants, who acquired their power from having been invested by the citizens with supreme authority, and placed in command of the military force, but only for a given time, and to deal with some definite emergency, but who became practically despots for life. (Grote, *History of Greece*, part ii. ch. ix.)

Æthæogamous (Gr. *ἄθῆος, unusual, and γάμος, marriage*). A name contrived to express more clearly the nature of what are called Cryptogamic plants; it being the opinion of the author of the name that the mode of propagation among such plants was not hidden, but only of an unusual nature. It has been confined by De Candolle to such as have vessels, as well as cellular tissue, in their organisation. In this sense it includes ferns, lycopodiums, and their allies.

Æther. [Æther.]

Æthogen (Gr. *αἶθων, brilliant, γίγνομαι, I become*). A compound of nitrogen with boron, remarkable for the intense luminosity which it exhibits in the flame of the blowpipe.

Æthroscope (Gr. *αἶθρος, clear, and σκοπέω, I view*). An instrument invented by Sir John

Leslie for measuring the relative degrees of cold produced by the pulsations from a clear sky. It consists of a differential thermometer, adapted to the cavity of a spheroidal cup of metal, the interior of which is highly polished, in such a manner that one of the balls occupies a focus of the spheroid; while the orifice of the cup is formed by a plane passing through the other focus, perpendicular to the axis. A lid of the same metal is fitted to the mouth of the cup, and only removed when an observation is to be made. Suppose the cup exposed to a clear sky; the cold pulses darted from the upper regions of the atmosphere, which enter the orifice of the cup, are reflected from the polished surface upon the ball A in the focus, while the ball B, lodged at the side of the cup in its widest part, is nearly screened from them, or receives only the small number which fall obliquely upon it. The two balls are thus exposed to different degrees of cold, the effect of which is immediately apparent, by the rise of the liquor in the stem of the thermometer, in consequence of the contraction of the air in the ball A. The effect may be augmented by covering the ball B, which is out of the focus, with a coat of gold or silver leaf. It is evident that the instrument is equally adapted to measure the effects of the radiation of heat, which will be manifested by the descent of the liquor in the stem. When applied to this purpose, however, the metallic cup becomes unnecessary; the hot pulses being mostly thrown back from the bright surface of the gilt ball, while they produce their full effect on the naked or sentient one. The æthroscope is thus converted into a pyroscope. (*Encyc. Brit.*, art. CLIMATE.)

Æthusa (Gr. *αἶθουσα, part. of αἶθε, I burn*).

AËTIAIOI

A genus of the Umbelliferous family, containing one common species, a weed in most cultivated ground. This plant, *Æ. Cynapium*, or fool's parsley, is an acrid poison, and from its resemblance to common plain-leaved parsley should be carefully discriminated. When in flower it is readily known by the presence of a few deflexed narrow involucrel leaflets on the outer side of each partial umbel. A safe mode, however, of avoiding at all times unpleasant consequences from its being mistaken for parsley, is to cultivate and use only the curly-leaved varieties of the latter: the leaves of the fool's parsley being perfectly flat.

Aëtialoi (Gr. from *æterós*, a pediment). In Architecture, the name given by the Greek architects to the slabs forming the face of the tympanum of a pediment. This word occurs in the Athenian inscription now in the British Museum, brought to England by Dr. Chandler, and relating to the survey of some temple at Athens.

Ætiology (Gr. *aitia*, a cause, and *lógos*, discourse). The doctrine of the causes of disease.

Ætites (Gr. *æterós*, an eagle). A term given by Pliny to hollow stones composed of several crusts one within another. By Kirwan the name is used to denote those kinds of iron-ore (clay-ironstone), which are composed of a reniform or globular crust of oxide investing an ochreous kernel. The name originated in the ancient belief that such stones formed part of an eagle's nest.

Affectation (Lat. *affectatio*). In the Fine Arts, an artificial show arising from the want of simplicity either in colouring, drawing, or action. Also, the over-charging any part of a composition with an artificial or deceitful appearance.

Affected, or Adaffected (Lat. *affectus*). A term used in Algebra. When applied to an equation, it signifies that two or more powers of the unknown quantity enter into the equation: thus, $x^2 + ax + b = 0$ is termed an *affected* quadratic, to distinguish it from $x^2 + c = 0$; which is a *pure* quadratic. When the term is applied to a quantity, it implies that the latter has a coefficient, or a proper sign: thus, in the quantity $+2x$, x is said to be affected with the coefficient 2, and with the sign $+$. Dr. Hutton thinks the term affected was introduced into Algebra by Vieta.

Afferent (Lat. *afferens*). The term, in Anatomy, applied to those lymphatic vessels which enter the lymphatic glands, subdivide, and form tortuous plexuses therein, whence other vessels proceed, converge, and unite into two or more efferent vessels which are larger than the afferent ones, and proceed towards the main trunk called 'thoracic duct.' The term *afferent* has also been applied to those nerves which convey impressions to the central axis, and which Hartley called 'sensory' nerves, in contradistinction to the efferent or 'motor' nerves.

Affetto, or **Affettuoso** (Ital.). In Music,

AFFINITY

a term prefixed to a movement, showing that it is to be performed in a smooth, tender, and affecting manner, and, therefore, rather inclining to slowness than the reverse.

Affidavit (Low Lat. *affido*, *I confirm by oath*). In Law, an oath in writing, sworn before some person who has authority to administer it. Affidavits, though once common in private matters, are now used in legal proceedings only.

Affiliation (Lat. *affilio*, *I adopt*). In Law, the assignment of a child to a parent by legal authority; as where the father of a bastard child is designated on the testimony of the woman, and the expenses of maintaining it cast upon him. By the Poor Law Amendment Act, s. 72, this can now only be done, after sufficient notice to the party intended to be charged, by an order of the court of quarter sessions, on the testimony of the woman, corroborated as to some material fact by other evidence. [BASTARD.]

Affiliated Societies, in Politics, are local societies, depending on a central society with which they correspond, and from which they receive directions. Such were the provincial Jacobin clubs, founded on the model of the Jacobin club of Paris. Such, also, were the Corresponding Societies in England, for the suppression of which the statute 39 G. 3, c. 79, was chiefly passed.

Affinity (Lat. *affinitas*). A relation of animals to one another, in the similarity of a greater proportion of their organisation: thus, a porpoise is said to have an affinity to man, because of its resemblance to him in the respiratory, circulating, and generative systems, in the brain, eye, ear, &c.; while it is said to have an analogy to a fish, because the resemblance is confined to external form. In short, affinity is that degree of relationship by which, in forming a concatenated series of animals, we pass from one to another by the closest gradations.

AFFINITY. In Botany, when the relation which plants or groups of plants bear to one another is very close, and depends on some striking resemblance between important organs. The term is used in contradistinction to analogy, when the resemblance lies between organs of less importance. Thus the foliage of *Lathyrus Nissolia* resembles that of a grass; but there is no affinity between the dicotyledonous *Lathyrus* and the monocotyledonous grass.

AFFINITY. In Law, as distinguished from consanguinity, signifies the relation which a man and woman by marriage contract towards the kindred of each other. From early times in the Christian church, this kind of relationship was esteemed to have the same effect as relationship by consanguinity in causing impediments to marriage; a rule chiefly founded, or alleged to be so, on the received interpretation of the eighteenth chapter of Leviticus. Until 1835, marriages of this class were valid only in England. In that year an act passed (5 & 6 Will. 4, c. 54) which prohibited

AFFINITY, CHEMICAL

them absolutely for the future, at the same time rendering valid those which existed.

Affinity, Chemical. The attractive force by which dissimilar substances combine with each other to produce chemical compounds. All natural and artificial substances are either simple or compound. The metals, for instance, are simple substances—no one of them having been as yet decomposed: water is a compound; it may be resolved into oxygen and hydrogen gases, which are therefore called its component parts. To enable substances to exert their mutual affinities, or to act chemically upon each other, the opposing powers of matter must be overcome, and they must be placed under circumstances favourable to the exertion of their mutual chemical attractions. Two solid bodies seldom combine, in consequence of their imperfect contact, and the immobility of their particles; hence the old axiom, *corpora non agunt, nisi fluida*. But to this there are exceptions: ice and salt, for instance, run down into liquid brine; dry oxalic acid and dry lime unite; and when sulphur and chlorate of potash are rubbed together, they act violently on each other. Even when one or both substances are fluid, heat is often requisite to diminish cohesion, and promote affinity: thus, mercury and iron combine with melted sulphur; and oxygen and hydrogen, and oxygen and carbon, require heat to effect their union. In some cases the action of the solar rays excites and increases affinity, as in the combination of hydrogen and chlorine.

The investigation of the relative proportions in which bodies combine, forms the basis of the atomic theory, or doctrine of chemical equivalents.

Many substances seem to unite in all proportions; but these are not strict cases of chemical combination: thus, water and sulphuric acid, and alcohol and ether, mix together in any quantities. Others unite indefinitely, up to a certain point: water, for instance, dissolves salt, in variable quantity, till the solution is saturated: we thus find that a given quantity of water is only able to retain a certain weight of salt in permanent solution. In these cases of indefinite combination, the affinities of the combining substances are usually feeble; but where their affinities or attractive powers are energetic, there is a remarkable tendency to combine in certain proportions only. Thus, sulphuric acid and lime unite in the proportions of 40 of the acid to 28 of the lime, and in no other or intermediate quantity: in such cases the acid and the base are said to neutralise each other; and such compounds are often called neutral salts, that is, salts in which the leading characters of the component parts are no longer perceptible, which are neither acid nor alkaline. When bodies combine in more than one proportion, which is often the case, the second, third, &c., proportions are simple multiples of the first: thus, 16 parts of sulphur combine respectively with 8, 16, and 24 of oxygen; in

these compounds the relative proportions of oxygen being as 1, 2, and 3. Again, 14 parts of nitrogen combine with 8, 16, 24, 32, and 40 of oxygen, forming five distinct compounds, in which the relative proportions of the oxygen are as 1, 2, 3, 4, and 5.

Where the combining substances are either naturally gaseous, or where they may be hypothetically so considered, it is obvious that, as their weights bear these simple relations to each other, their bulks or volumes will do so likewise: thus, in the case of the compounds just noticed, 1 volume of nitrogen will combine respectively with $\frac{1}{2}$, 1, $1\frac{1}{2}$, 2, and $2\frac{1}{2}$ volumes of oxygen; or, what amounts to the same thing, 2 volumes of nitrogen will combine with 1, 2, 3, 4, and 5 volumes of oxygen.

As bodies thus combine with each other in definite proportions; it is obvious, that if we select any one substance as unity, or = 1, all other substances may be represented by numbers equal to the weights in which they respectively combine with each other, and with the unit. Upon this principle of numeric representation, hydrogen, which is the lightest known substance, is assumed as unity; the compound of hydrogen with oxygen is water, in which 1 part by weight of hydrogen is combined with 8 of oxygen, to form 9 of water; hence, in a table of atomic weights, definite proportionals, or chemical equivalents, (for all these terms have been applied to such numbers), we have—

Hydrogen represented by 1	
Oxygen	" " 8
Water	" " 9

And in the above series of nitric compounds we have, in the first of them, 14 of nitrogen combined with 8 of oxygen; and, accordingly, calling 14 the equivalent of nitrogen, and 8 the equivalent of oxygen, we have the following equivalents of their compounds; and it may be presumed that these numbers represent the weights of the combining atoms of those bodies:—

Atoms of nitro- gen	Equivalents, or combining weights, of nitro- gen	Equivalents of the compounds
14 + 8	=	22 nitrous oxide
14 + 16	=	30 nitric oxide
14 24	=	38 hyponitrous acid
14 32	=	46 nitrous acid
14 40	=	54 nitric acid

This table also shows the nomenclature commonly applied to the compounds; the termination *ous* indicating the minimum of oxygen, the termination *ic* the maximum; the term oxide implying generally all those combinations of oxygen which are not sour, such being called acids. More frequently the relative proportions of oxygen in the oxides are designated by the first syllable of the Greek ordinal numerals: thus we have protoxides, deutoxides, tritoxides, &c.; and when the base is saturated

with oxygen, the compound is termed a peroxide. When the same substance forms three or four acids, the term hypo is conveniently introduced with the termination *ous* or *ic*, as shown in the following table of acids of sulphur:—

sulphur	of oxygen	Equivalents of sulphur	Equivalents of the acids
1 + 1	16 + 8	= 24	hyposulphurous
1 + 2	16 + 16	= 32	sulphurous
1 + 3	16 + 24	= 40	sulphuric

There is also an acid of sulphur intermediate between sulphurous and sulphuric, composed of 1 atom of hyposulphurous acid and 1 of sulphurous acid; ($24 + 32 = 56$) or of 2 atoms of sulphur and 3 of oxygen: this is appropriately called the hyposulphuric acid. The terms *aequi* and *bi* are sometimes used to designate intermediate and double compounds of acids, or other bodies with bases: thus, we have three compounds of carbonic acid with ammonia, in which 1 proportional or atom of ammonia is respectively combined with 1, $\frac{1}{2}$, and 2 of carbonic acid, and these we call the carbonate, sesquicarbonate, and bicarbonate of ammonia. For a table of the equivalent numbers of the simple substances, see EQUIVALENTS.

Change of form and change of properties are the common consequences of chemical affinity. We observe, 1. Solids forming liquids (ice and salt). 2. Solids forming gases (explosion of gunpowder). 3. A solid and a liquid producing a solid (lime and water). 4. A solid and a liquid producing a liquid (all common cases of solution; as of salt and sugar in water). 5. Liquids producing solids (solution of carbonate of potassa mixed with muriate of lime). 6. Liquids producing gases (alcohol and nitric acid). 7. Gases producing solids (ammonia and muriatic acid). 8. Gases producing liquids (chlorine and olefant gas).

The density of bodies is also materially affected by chemical combination; the density of a compound is very rarely the mean of its components, but generally increased: thus, almost all gaseous compounds occupy less bulk than their elementary gases in a separate state; there are, however, cases in which 1 volume of one gas, combined with 1 volume of another, produce exactly 2 volumes of a compound gas, the density of which is, of course, the mean of that of its components; and again, in the combinations of some of the metals with each other, and with sulphur, the density of the compound is below the mean of its elements. When certain liquids are mixed, great and immediate increase of density ensues, and much heat is evolved (sulphuric acid and water). Change of form and of density are often attended by remarkable changes in other qualities: thus, tasteless bodies produce active compounds (oil of vitriol is composed of oxygen, sulphur, and water), and active substances produce inert compounds (sulphuric acid and caustic potash produce the inert salt, sulphate of potash); so that it is

utterly impossible, by any *à priori* reasoning, to determine what will be the consequence of chemical combination: useless elements produce useful compounds, and useless compounds yield useful elements.

Another important and curious consequence of chemical action is change of colour: the vegetable blues are generally reddened by acids, and rendered green by alkalis; the alkalis render many of the reds purple; and of the yellows, brown: chlorine destroys most colours; so does the joint action of light, air, and moisture. [NOTATION, CHEMICAL.]

Affirmation (Lat. *affirmatio*). In English Law, a solemn declaration made, in cases authorised by law, by persons statutorily relieved from the necessity of taking oaths. This relief, early granted to Quakers and members of some other persuasions, was extended by the Common Law Procedure Act, 1854, to all persons having conscientious objections. A false declaration or affirmation is punishable as perjury.

Affirmative. In Logic, this term denotes the quality of a proposition which asserts the agreement of the predicate with the subject.

Affirmative Quantity. [POSITIVE QUANTITY.]

Affirmative Sign or Positive Sign.

The sign of addition, marked +, meaning plus, or more. Dr. Hutton observes, that the early writers on algebra used the word plus in Latin, or piu in Italian, for addition, and afterwards the initial *p* only as a contraction, as they used minus or meno, or the initial *m* only, for subtraction; and thus their operations were denoted in Italy by Lucas de Burgo, Tartalea, and Cardan, while the signs + and — were employed much about the same time in Germany by Stifelius, Scheubelius, and others, to denote the same operations.

In Grammar, a syllable attached to the end of a class of words, determining their meaning. Thus, a class of adverbs in English is determined by the affix *ly*; strongly, weakly, &c. A prefix is a syllable so attached at the beginning.

Affrontée (Fr. *affronter*, to face). In Heraldry, a term applied to animals placed to face each other.

Afrancesados (Span.). In Modern History, a denomination given in Spain to the party which attached itself to the cause of the French, or of the intrusive king Joseph, during the war of independence, 1808—1814.

Africa. The continent of Africa is about 5300 miles in length from north to south, and nearly as much in extreme breadth from east to west; but its shape is triangular, and its area does not exceed twelve millions of square miles. The total length of its coast line is less than 16,000 miles, showing an amount of deviation from a straight line, and a smallness of indentation, extremely remarkable. It has few navigable rivers, and the interior is therefore reached with difficulty. The mouths of its rivers are all swampy, and extremely subject to malaria. Its lakes are numerous and perhaps occasionally

AFRICA

connected, but generally mere large ponds with no defined margin. Its deserts are large and for the most part are without water courses. In many important respects, the interior of Africa is totally unlike the interior of Europe or Asia, or either of the two Americas. It bears a kind of analogy to the interior of Australia, but there are points of essential difference.

Till within the present century, the interior of Africa was very imperfectly known to the inhabitants of Europe, although its northern part has been traversed from time immemorial by Arabs.

As now known, the northernmost part of this continent, consisting of the Atlas mountains, more properly belongs to the European land. The rest between the Atlas chain and the equator consists of the GREAT SAHARA [which see], terminated eastwards by the Nile and Abyssinia, which is a mountain country. The southern portions are for the most part vast tracts of nearly level land, enclosed by coast ranges, and watered by rivers which carry little water into the sea. The coast range is a wide table land, on which are lakes at high levels. An extensive desert occupies the whole of the southern district within the table land for a considerable distance, but it is only barren during the dry season.

Africa abounds with large quadrupeds, and is chiefly peopled by various tribes of black or coloured men. These for the most part are low in the scale of intellect, especially when inhabiting the low swamps and unhealthy lands of the coast. The vegetation is peculiarly interesting.

Africa contains much mineral wealth. Gold has been found abundantly in the coast range on the west side, and exists also on the east. Copper also abounds, and has been worked in the mountains of the Lesser Atlas, in the coast range on the west coast near the Cape of Good Hope, and elsewhere on the south coast; and also on the east coast in various places iron would seem to abound.

The greater part of the African coast being within the tropics, and the rivers and streams for the most part choked before entering the sea, the climate of the coast is generally very unhealthy. Fevers and miasms also abound in many parts of the interior that have been visited. The country near the Cape of Good Hope is generally healthy.

Lake Systems.—The lake systems of Africa are strictly connected with the physical structure of the country, and are of great importance to a right understanding of its physical geography. They are of two classes:—those of the one occupying depressions in the steps of table land, which surround the whole of the continent south of the equator, and those of the other forming mere pools or expansions of the rivers in the central districts.

Of the former the lake Tanganyika is an example occupying a depression of a thousand feet in a plateau of three thousand feet and

receiving the drainage of a large area. It is about 600 miles from the coast. A little to the north, but nearer to the coast, is the great lake Nyanza, at a higher level, and running northwards towards the equator, connecting with the Nile. South of this, at some distance, but probably part of the same chain, is the lake Shire, partially explored by Dr. Livingstone. All these, and probably many other lakes on the east side of Africa, occupy similar depressions in the great plateau, and are more or less parts of one system.

The lakes on the western side and in the north of Africa near the equator are in the lower lands, and consist of expansions of rivers or of pools enlarged by annual or occasional rains. Such are lake Tchad, lake Ngami, and the Bahr-el-Gazul, an occasional expansion of the Nile recently explored by Consul Petherick. There are probably others in the course of the Zambesi.

Mountain Chains.—Contrary to the opinion long entertained, there seems no reason to suppose that the mountain systems of Africa at all resemble those of Asia, Europe and America. Except the Great Atlas, a chain which may be regarded as part of the great mountain axis of the Old World, branching off on the south of the Mediterranean basin, there is no transverse chain in Africa, unless the reports and statements made by M. du Chaillu, on the west coast, possess more value than the evidence warrants us in supposing. On the east side indeed, in and near Abyssinia, is a very lofty mountain district extending from near the equator towards the north, but this seems rather the termination westwards of the great Asiatic high lands than part of a separate axis. All the rest of the African high lands appear to be rather plateaux than chains: African land therefore consists of a triangular plain of low elevation surrounded and enclosed by high table land rising at intervals into mountains.

Rivers.—In accordance with the peculiar condition of the mountain chain and table land of Africa, and in connection with its lakes, the river systems are few in number, and, with the exception of the Nile, and perhaps the Orange river, have little resemblance, in the mode of their passing through and collecting the drainage of the land, to the streams of most other countries. The Nile probably drains only the north-eastern extremity of Africa; for although some of its affluents take their rise south of the equator, these probably connect themselves with the great chain of lakes of which the Nyanza is the largest. Some of the actual sources of the Nile near the equator have lately been traced by Capt. Speke, but it has not yet been decided whether or not there is an important branch coming in from the west. Of the other rivers of Africa, the Zambesi and the Niger or Quorra are the largest and most important. The Orange and the Ogobai are also of considerable interest. The latter is supposed by M. du Chaillu to take its rise in the far interior of the continent.

The Nile is one of the principal rivers of the world, both in the direct length of its course, which is more than two thousand miles, and in the vast area it drains, which is estimated at three quarters of a million of square miles, and may be much larger. Belonging to the Mediterranean system of drainage, it penetrates Africa south of the equator; and no other stream of any kind carrying off water from the eastern half of Africa in north latitude can be even named. The Quorra or Niger is perhaps little inferior either in drainage area or in length of course to the Nile, though much less known. It drains the western part of Africa north of the equator, but south of the desert.

The Zambesi, whose course has been clearly indicated by Dr. Livingstone, is, however, yet more remarkable. Rising near the table land of the west coast near Loanda, about 12° south of the equator, and fed by numerous streams draining (if the term can be properly applied in this case) a vast irregular oval area, part of the central plateau of Africa, this remarkable stream continues its course sometimes smooth, wide and deep, sometimes broken by waterfalls of great beauty, sometimes breaking up into a multitude of streamlets; and at length the whole body of water, after coursing for two or three thousand miles in the interior, is almost lost, or at least has only an obstructed and dangerous channel to the sea on the south-east coast, oozing through a wide indentation of the table land without dignity or grandeur. Close to the coast it receives a large tributary, connected with the great chain of lakes on the plateau parallel to the east coast.

The rivers of Africa thus afford matter for study not less interesting and exceptional than the lakes and mountains. Everything in this continent is indeed unlike the corresponding phenomena in Europe, Asia, and America, and the interior more resembles a depressed basin than a range of land brought up by a mountain axis. As we have already remarked, the condition of Australia presents some analogy, but the differences are marked and characteristic.

Africa is almost without evidences of volcanic action, except on the north-east coast in the lofty mountains near Abyssinia.

Aft. A relative term used on board ship to signify position behind or near the stern.

After-damp. This is chiefly carbonic acid gas. It is the invariable product of combustion of coal, fat, gas, &c., but under ordinary circumstances is so rapidly diffused into, and diluted by, the air, that its suffocating action on the system does not obtain. In coal mines, however, it is produced during an explosion at the expense of the oxygen of the air of the mine, and then generally contains carbonic oxide, thus forming with the residual nitrogen an atmosphere in which animal life cannot possibly be sustained.

Aftermath. In Agriculture, grass which is mown after the first crop of hay has been taken away, instead of being eaten off by stock.

Age. A title of dignity among the Turks

and Persians, given to various officers, as the aga of the janissaries, &c. It is also a common epithet of respect in addressing a distinguished person.

Agalmatolite (Gr. *εἰδωλον*, an image, and *λίθος*, stone). An altered clay or clay-slate, which is carved into images, &c., by the Chinese. It occurs massive, of various shades of greenish-grey, passing into yellowish-grey and yellowish-brown, &c.; translucent; feels rather greasy, is sectile, and yields to the nail. It is found in Cornwall at the Restormel Iron Mines, of a pale flesh colour; at Glyder Bach, in Caernarvonshire; Lugganure Mines, Co. Wicklow; also in China, Saxony, Transylvania, Norway, &c.

Agama. The name of a lizard, employed by Cuvier to designate the first section of the Iguanian sauria, or *Agamidae*; which section is characterised by the absence of palatal teeth. The Agamoid lizards include several genera, which are numerous in species, and they are distributed over the warmer parts of America, Africa, Asia, and Australia.

Agamous (Gr. *ἀγαμος*). A term substituted by some writers for *cryptogamic*, because such plants were supposed to have no organs analogous to sexes: it is, however, usually limited to such groups as Conferve, Lichens, and Fungi.

Agapæ (Gr. *ἀγάπη*, love). Love feasts, in use among the primitive Christians. After the celebration of the communion, the oblations which had been made in the temple, consisting of meat and bread which the rich had brought from their houses, were consumed at a common feast. There is some dispute whether in the apostolic times this feast did not take place before the communion, in more exact accordance with the circumstances attending the institution of the sacrament. The *agapæ* or feasts in churches were prohibited by the Council of Laodicea, A.D. 361, and the third of Carthage, A.D. 397.

Agapetæ (Gr. *ἀγαπητός*, beloved). Among the early Christians, women under vows of virginity who undertook to attend on and serve the clergy. The practice was condemned by St. Cyprian as well as by the acts of several councils.

Agaphite. [TURKISH.]

Agaric (Gr. *ἀγάρικον*). A genus of Fungi comprehending many hundred species, among which are, *A. campestris*, the common mushroom, and some others, which are delicate articles of food; *A. muscarius* and others that are dangerous poisons; many of the disgusting deliquescent fungi called toad-stools; and numerous beautiful little ephemeral species, which appear to be harmless. *A. olearius* is remarkable for being phosphorescent. These plants uniformly grow in decaying animal or vegetable matter, among which their stem, or spawn, as it is commonly called, ramifies. After the spawn has arrived at the proper age, it ceases to branch, collects into parcels, and generates from those parcels the fructification, which forces its way into the light under the

AGARIC MINERAL.

form of the agaric. The cap is the part where the spores or seeds for reproducing the species are generated; they are formed within the plates or gills that lie on the under side of the cap, and are little variously coloured round bodies which, when they are collected in great quantities upon a sheet of white paper, have the appearance of exceedingly fine dust. 'Fairy rings' are caused by the underground stems of agarics, which branch from a common centre, and only protrude their fructification at the circumference.

Agaric Mineral. A soft and friable kind of nearly pure native carbonate of lime, found in the clefts of calcareous rocks, in limestone caverns, and at the bottom of certain lakes, the waters of which are charged with lime.

Agastries, Agastria, Agastrica (Gr. ἀγαστήρ, a stomach; stomachless). A term which has been applied to certain animalcules, on the erroneous supposition that they were devoid of internal digestive cavities. [POLYGASTRICS.] The term is still applied to a family of Medusæ.

Agate (Gr. ἀγάθης). A siliceous mineral of which the base generally appears to be chalcedony; but carnelian, jasper, amethyst, and other allied minerals, often enter into its composition. Owing to its hardness, which makes it take a fine polish, the variety of its colours, and the beautiful manner in which these are mixed and arranged, the Agate is much used for making ornaments. Most of the Agates of commerce are brought in a polished state from Oberstein, in Saxony, but they are also found in Scotland (SCOTCH PEBBLE), Siberia, Arabia (MOCHA STONE), India, Surinam, and many other countries, in the form of rounded nodules and hollow geodes embedded in trap rocks and serpentine. The various kinds of Agate, *Fortification Agate*, *Ribbon Agate*, *Moss Agate*, *Brecciated Agate*, &c. are described under their respective names. The name is said to be derived from that of the Achates, a river in Sicily.

Agathodæmon (Gr. ἀγαθὸδαίμων). The good Genius or spirit, originally, perhaps, only an epithet of Zeus. (Pausanias, viii. 36, 3.) [DÆMON.]

Agathotes (Gr. ἀγαθότης, goodness). A genus of the family of Gentians, the dried stems of a species of which, *A. Chirayta*, the chiretta, a native of Northern India, furnish a very pure bitter, very similar to gentian, and used medicinally.

Agave (Gr. ἀγανός, admirable). A genus of plants found in the temperate parts of America, resembling aloes in their mode of growth and general appearance, but differing in having an inferior ovary, and in their sensible properties. The best known species is *Agave americana*, called the American aloe, which has been naturalised on the coasts of the Mediterranean, where it assists, with *Opuntia vulgaris*, the palmetto, and date palms, to give a tropical air to European scenery. It is many years preparing the materials for its gigantic pyramid of

AGE

flowers, and is so exhausted by the effort that it quickly afterwards perishes. A sweet sap flows from its inward stem, and upon fermentation becomes an intoxicating beverage, yielding by distillation a powerful ardent spirit. Hemp of considerable strength is manufactured from its leaves. The genus *Agave* is the type of one of the subdivisions of amaryllidaceous plants.

Age (Fr. *âge*). Means generally a definite period or length of time. For the origin and history of this word, see Max Müller, *Lectures on the Science of Language*, First Series, p. 279, (1861).

AGE. As applied to man, ago may either mean the whole of his life, or a portion of it. It is usual to divide the whole period of human life into four parts or ages. The first, or infancy, extending to the fourteenth year; the next, or youth, from the fourteenth to about the twenty-fifth; manhood, from the twenty-fifth to the fiftieth or sixtieth; and the last, or old age, filling up the remainder. Ovid ingeniously compares these four ages to the four different seasons of the year. — *Metamorph.* xv. 200. These divisions are, however, in a great degree arbitrary; and very frequently they have been extended to six, the first being divided into infancy and childhood, and the last into old age and extreme old age. Sometimes, also, the life of man is supposed to be divided into seven ages, the leading characteristics of which have been most admirably depicted by Shakespeare, *As you like it*, Act ii. scene 7.

For a scientific discussion of this subject, see MORTALITY.

AGE. In Chronology and History, age is sometimes used as synonymous with a century, and sometimes also with a generation. Writers differ in respect to the period included under what is called the *middle ages*; but they are commonly understood to begin with the reign of Constantine, and to extend to the fifteenth or the early part of the sixteenth century. The æra of the invention of printing may perhaps be most fitly assigned as their termination. The characteristics which distinguish the middle ages from more modern times are examined by Dr. Arnold, *Introductory Letters on Modern History*, p. 93, &c.

AGE. In Law, is the period at which individuals are qualified to undertake certain duties and offices. By the common law of England, a man at fourteen is at the age of discretion, and may then appoint guardians, and marry with their consent: at twenty-one he is of full age, and may, consequently, exercise any civil privilege to which he may otherwise be entitled, that is, he may elect or be elected to parliament, be appointed a judge, alienate lands, make valid contracts (not voidable, as those of infants are in general), &c. But no person can be admitted in England to deacon's orders till he be twenty-three years of age, nor to priest's till he be twenty-four. At twelve years a woman may marry, provided she have the consent of her parents or guardians; and at twenty-one she is her own

AGE

mistress, and may dispose of herself and her estates.

Infants under seven years are held by the law of England to be incapable of committing felony. If persons above that age, and under fourteen, commit felony, they are *prima facie* entitled to an acquittal; but if it appear to the court and the jury that the accused was *doli capax*, or clearly understood the nature of the crime he was committing, they may proceed on the principle that *malitia supplet aetatem*, and subject the offender, as, in point of fact, has been repeatedly done, to the extremest penalty of the law. Persons above fourteen are treated in this respect as if they had arrived at full age. (*Blackstone*, book iv. cap. 2.)

At Rome, the *consular age*, or the age at which a person became capable of holding the consular dignity, was fixed at forty-three, though in extraordinary cases this rule might be set aside. In France, a man is not allowed to exercise the elective franchise till he be twenty-five years of age; in some of the American states judges are obliged to retire when they have attained to a certain age, which is sometimes as early as sixty. The same age (sixty) is fixed by the English superannuation law of 1857 as that at which public servants may be permitted to retire on pension. According to Aristotle, thirty-five is the age at which the human body attains its perfection; forty-nine that for the mind—a notion which seems connected with the mystical properties of the number seven, the multiples of which form most of the received epochs in the age of man.

Age. In Literature, age is a period usually bearing the name of some powerful sovereign, or other prominent person, who flourished during that period. Of these ages, the most memorable are the age of Pericles, the Augustan age, the age of Leo X., &c.

Age. In Mythology, age means one of several periods through which the poets supposed the world to have passed. In Hesiod the Golden, Silver, and Brazen Ages are followed by the Heroic, after which comes the Age of Iron, which still continues. (*Grote, History of Greece*, vol. i. ch. 2.)

Agenda (Lat. *things to be done*). Small books are now published under this title, in which may be set down under their proper heads the things to be daily attended to.

AGENDA. In Divinity, articles of moral practice, in opposition to *credenda*, articles of faith. Also, the ritual of a church, and the books containing it.

Agent (Lat. *agens*). In Law, is a person authorised to do some act or acts in the name of another, who is called his *principal*. An agent may, in general, be appointed by bare words, or his appointment will be inferred from circumstances; but for some purposes specified by the Statute of Frauds, his appointment must be in writing. The agent of a corporation must, in general, be appointed by deed. If an agent has engaged to perform certain duties for a consideration, the performance may be enforced

AGGREGATE ANIMALS

in law. But against an unremunerated agent, the principal can only recover damages for misconduct in the performance, and cannot compel him to proceed. With respect to the dealings of third parties with an agent, some general rules of law are, that the extent of an agent's authority is, as between his principal and third parties, to be measured by the extent of his usual employment; that the representation of an agent about the subject-matter of a contract which he is negotiating for his principal will, if made during the course of the negotiation, bind the latter; that payment to an agent, in the course of his employment, is payment to the principal; that the principal is, under many circumstances, responsible in civil actions for the negligence or fraud of his agent, but not criminally liable for his acts, unless done under an express command.

AGENT. In Diplomacy, a general name, comprising several ranks:—as, 1. Ambassadors. 2. Envoys extraordinary and Ministers plenipotentiary. 3. Ministers resident. 4. *Chargés d'affaires*. 5. Secretaries of legation, &c. In common language, however, the highest officer employed by one power at the court of another is usually termed the agent of that power at the court in question. [*DIPLOMACY.*]

Ageratum (Gr. *ἀγρίπαρον*). The name of this genus of *Compositæ*, which is adopted by the moderns from Dioscorides, was, it is supposed, applied by him to plants such as we now designate 'everlastings.' The modern genus contains but few species, one or two of which are cultivated for ornament, but none have any useful properties. Some of the plants once included in *Ageratum* are now referred to *Eupatorium*, *Stevia*, *Colestina*, *Piqueria*, and others. *Piqueria trinervia*, formerly called *A. febrifugum*, a Mexican herbaceous plant with white flowers, is used in Mexico as a remedy in intermittent fevers.

Agglutinate Languages. In Grammar, a term applied to the Turanian family of languages, to express the character of their formation. In the Aryan and Semitic languages conjugation and declension are the result of *gluing on* pronouns to verbs and nouns; but in them these terminations have coalesced so as to form practically a single word, and have, therefore, in greater or less degree, lost their original and independent force. In the Turanian languages the declension and conjugation can still be taken to pieces, and the affixes are so to be distinct from the roots to which they are appended, as in Mongol, Turkish, &c. (*Max Müller, Lectures on the Science of Language*, First Series, Lect. viii.)

Aggregate Animals. This term is applied to those animals which are collected together in a common enveloping organised substance containing numerous compartments, from each of which a distinct occupant sends forth a circle of organs to collect food, which, after assimilation, is carried by a common and continuous system of vessels for the support and enlarge-

ment of the common dwelling. Examples of animals so associated or aggregated occur in the class Polypteri, where they form most of the orders; also in the class Acalephæ, forming the Polytoma; and in the Acephalous Mollusca, forming the genera Botryllus, Pyrosoma, and Polyclinum.

Aggregated (Lat. *adgregatus, associated with*). In Mineralogy and Geology, a mineral or rock is said to be aggregated, when the several component parts only adhere to each other to such a degree as to be separable by mechanical means. Thus, in the case of granite, which is an aggregated rock, the Quartz, Felspar, and Mica, of which it is composed, may be separated mechanically.

Aggregated Glands. Those secreting organs in which a number of compound vesicles or *acini* are arranged in groups, forming lobules. [CONGLOMERATE.] Such are the so-called mucous glands of the mouth, trachea, and vagina; the tonsils, salivary, pancreatic, and mammary glands; the lachrymal and Brunonian glands; Cowper's glands; and the prostate gland.

Agilia (Lat. *agilis, swift*). A family of Rodents in the system of Illiger, including squirrels and dormice.

Agio (Ital. *aggio*). A mercantile term, denoting the percentage difference existing between the values of the current and standard moneys of any place. Also, the rate of premium which is given, when a person having a claim which can only be legally demanded in one metal, chooses to be paid in another. Thus, in countries where silver is the only legal standard, a large payment in silver is so inconvenient, that the receiver will often pay a small premium for the convenience of receiving gold: this premium constitutes the *agio* on gold.

Agiotage. A term employed to designate the sort of manœuvres by which speculators in the public funds contrive, by disseminating false rumours, or otherwise, to lower or enhance their price. It is sometimes also, though less commonly, applied to the machinations of those who endeavour, by similar artifices, to raise or depress the prices of commodities.

Aglossymandrum (Gr. *ayos, holy*, and *σημαίνω, I show by a sign*). A wooden instrument used in Christian churches in countries under the dominion of the Turks, who forbade the use of bells.

Agistment. In Law, from the old French word, *agister*, which signifies a licence granted for cattle, viz. to be harboured, or, in legal phrase, *levant and couchant*, on the land. A contract by which A.'s cattle are taken into B.'s ground, to remain there at a stipulated sum, paid periodically. Agistment is also used for the profits of such feeding. The 'Tithe of Agistment,' or of cattle and other produce of grass lands, demanded by the Irish clergy, was resisted, in 1720, by the landlords, and in effect abolished by a resolution of the Irish house of commons (1735). By the act of

union, this resolution was passed into law; and thus the tithes of Ireland have, in effect, been thrown on the owners and cultivators of arable land. (*Ed. Rev.*, vol. xxxiv.; Wakefield's *Ireland*, vol. ii.)

Agminate Glands (Lat. *agmen*). The glands of Peyer, in the small intestines, where they are aggregated in groups, are so called: these groups are of various sizes, and usually of an oval form.

Agnate (Lat. *agnatus*). In Roman Law, *agnates* are those who descend through males from a common ancestor; in opposition to *cognates*, i.e. all the descendants of a common ancestor, whether through males or females. Thus, in France, by Salic law, the hereditary crown passes by right of *agnation*, females being excluded.

Agnesite. An earthy steatitic mineral found at Iluel Coates, near St. Agnes, in Cornwall. It is probably an impure kind of bismuth-ochre.

Agnoetæ (Gr. *ἀγνοῦν, I do not know*). In Ecclesiastical History, a sect of the sixth century, who maintained that Christ, in His human nature, was ignorant of many things, and particularly of the day of judgment. An earlier sect, so called, questioned the omniscience of God.

Agnomen (Lat.). Besides the *prænomen*, *nomen*, and *cognomen*, the Romans sometimes had a fourth name (*agnomen*), which was derived from some illustrious action or remarkable event. Thus, two Scipios had the name *Africanus* given them, on account of their victories over the Carthaginians in Africa. The younger of these celebrated generals had a second *agnomen*, viz. *Æmilianus*, because he was the son of L. Paulus *Æmilius*, and adopted into the family of the Scipios.

Agnon. A name applied by Fabricius to a genus of dragon-flies, having the wings erect when at rest, the eyes distinct, and the outer divisions of the lip bifid.

Agnostus (Gr. *ἀγνωστος, unknown*). A name devised to express the obscure nature of genus of Trilobites (fossil Crustaceans), to which it is attached; the genus is characterised by the semicircular or reniform shape of the body, which in all other Trilobites is ovate or elliptical.

Agnus Dei (Lat. *Lamb of God*). 1. A prayer of the Roman Catholic church, which begins with the words, 'Agnus Dei qui tollis peccata mundi.' 2. Images of wax, impressed with the figure of the Lamb, consecrated by the pope, and distributed to the faithful.

Agomphians (Gr. *ἀγρομφιος, without grinder-teeth*). A term applied by Ehrenberg to those Rotifers of which the jaws are deprived of teeth.

Agonalia (Lat.). A Roman festival celebrated several times a year, in honour of the guardian deities of the state.

Agora (Gr. from *ἀγείρω, I gather*). The market place of a Greek town, which was generally used also as the place where the assembly

AGORANOMUS

blies of the people met. It answers to the Latin term forum. From agora is derived

Agoranomus (Gr. ἀγορανόμος). The title of an Athonian magistrate, forming one of a body of ten, or, as some say, fifteen, persons, whose duty it was to superintend the markets, and collect the customs imposed on certain articles.

Agrarian Laws (Lat. agrariæ leges, from ager, a field). Under this term are comprehended the enactments which were carried, or attempted to be carried, at Rome by the plebeians and their partisans, in opposition to the patricians, touching the distribution made of the public lands accruing to the state by conquest. These were leased out to the patricians by the state at a moderate or nominal rent, while the plebeians gained nothing by them. The object of the agrarian laws, which did not interfere with private freehold property, was to obtain for the plebeians a share in these lands, to restrict the quantity occupied by individuals, and to cause a real rent to be paid from them for the support of the army. The most celebrated movers of these laws were, Sp. Cassius, Licinius, and the two Gracchi. For a more impartial investigation of them than can be found in ancient writers, (for Cicero, from his aristocratic partisanship, has much misrepresented the objects of these reformers, and the character of the laws they sought to introduce,) see Niebuhr's *Roman History*, and Sir G. C. Lewis *On the Credibility of Early Roman History*. In consequence of the misrepresentations here referred to, the term 'Agrarian law' in Politics now generally serves to denote a law for the spoliation of individuals, by reducing landed property in private hands to a fixed amount.

Agreement (Fr. agrément). In the *Fine Arts*, a certain degree of resemblance between the parts, in style and character, so that they may seem to belong to each other.

AGREEMENT. In Law, that which is consented to by two or more parties. Agreements are divided into executed and executory. By the Statute of Frauds, 29 Car. 2. c. 3, no action can be brought to charge a defendant on any agreement upon consideration of marriage, or on any contract or sale of lands, &c., or any interest therein, or any agreement not to be performed within one year, unless such agreement, or some memorandum or note of it, be in writing, signed by the party to be charged therewith, or some other person by him thereto lawfully authorised.

The remedy which law affords for the breach of an agreement is only by way of damages. But equity will in general compel the specific performance of any contract or agreement for the non-performance or breach of which a court of law could have awarded damages. The principal exception to this rule is, where the agreement is of such a nature that its breach can be or was intended to be compensated by damages.

Agricultural Chemistry. That part of

AGRICULTURAL GEOLOGY

chemical science which relates especially to agriculture. It more particularly demands a knowledge of the composition of the atmosphere, the soil, and the plant, and their action upon each other in the presence of moisture; and enables the farmer to manure, in the broadest sense of the word, that is, renew impaired soil, and improve land that naturally is unfertile, to the greatest advantage. The successful and economical operations on farm produce depend also to a large extent on chemical principles, and can only be fully appreciated and best carried out by individuals possessing some knowledge of chemistry.

Agricultural Geology. To the agriculturist geology is chiefly valuable as teaching the probable resources of a district in soil, subsoil, and mineral manure. So far as relates to DRAINING and WATER-SUPPLY, they will be found explained in those articles.

A geological map explains (by referring to the index of colours) the kind of rock that may be expected to underlie any particular district. It is quite possible that the rock near the surface may differ widely from the soil, for the fine particles of the latter may have been conveyed by water from a distance. The map therefore teaches what the soil conceals, and may lead to important practical results. Thus, if a geological map should indicate the probability of limestone or sand beneath a stiff clay, it might be worth while to bore to prove the existence of the limestone or sand, and afterwards to sink a quarry to obtain material for liming the clay or converting the clay into loam. Many such illustrations of the use of geology to the agriculturist will readily suggest themselves.

Generally speaking, the subsoil is derived directly from the underlying rock, and the soil is derived from the subsoil; a certain amount of disintegration and decomposition, always going on under the ordinary influences of weather, tends to perpetuate this condition, and thus in most cases the soil indicates the rock. In any estimate of the value of property, the nature of the underlying rock comes into consideration, for both the depth and texture of the soil are almost sure to depend on the rock beneath, and the fertility is evidently dependant on these. The mechanical condition of a soil may often be greatly altered by mixture with a favourable rock, out of sight, but whose existence in the neighbourhood is learned by geological investigation.

In the valuation of estates the importance of geology is especially felt, inasmuch as the resources of the land cannot be fairly estimated without including this element.

To the farmer it is often desirable that he should know the probable result of deep draining and deep ploughing. These depend greatly on the nature of the rock, the dip and compactness of the strata, and the form of the surface in reference to the stratification. Thus, in all respects some knowledge of geology is necessary for agricultural purposes.

Even the fossils that are found in, and are

AGRICULTURE

characteristics of, rocks are occasionally valuable for practical work. Thus the *Corporalls* recently discovered and worked in the east of England have greatly increased the value of the lands where they occur, and shells are sometimes very valuable. Certain rocks seem especially rich in phosphates, and others, owing to the presence of other mineral phosphates, are of extraordinary fertility. Such are the *Tchor nozem* or black earth of the Aralo-Caspian hills, and the *Regur* or cotton-soil of India.

Agriculture (Lat. *agricultura*, from *ager*, a field, and *colo*, I till). This art may be defined to be that of cultivating land in fields, or in large quantities, as opposed to horticulture, which is the art of cultivating land in gardens, or in small quantities: or, agriculture may be defined as the art of cultivating land with the plough, and horticulture that of cultivating it with the spade. The restricted meaning of the word agriculture, therefore, is simply the art of cultivating fields but its more extensive and general meaning includes the whole business of the farmer, which comprehends, in addition to raising corn and other crops, the management of live stock. As a general term, the word agriculture is also frequently considered as including every description of territorial improvement; thus it is made to comprehend embanking, road-making, draining, planting, and sometimes even horticulture. In this sense the word agriculture is used by the French writers on the subject.

We shall here consider the term agriculture in its general acceptance in Britain, and in other countries where the English language prevails, as only including the culture of field crops, and the rearing and managing of domestic animals, on a large scale; and we shall give a very concise outline of its origin, history, theory, and practice.

The origin of Agriculture must doubtless have been coeval with that of fixed property. In the primal state of society, the sole riches of the husbandman consisted of flocks and herds, which were kept in a state of movement from one point to another, in search of pasturage and water; but as population increased, mankind adopted a fixed abode; this could only be done by bestowing on the site a certain degree of labour and care, which became, as it were, the price paid for constituting it private property. At this point in the progress of civilisation agriculture may be said to have commenced. Previously, the natural products of the soil were merely consumed where they were found; but now man sought to increase them by culture.

History of Agriculture. The culture of the land will be found to have depended, in every country, principally on its climate and its civilisation; though partly, also, on its government and population. In the warmer climates, where nature produces fruits in the greatest abundance for the food both of men and animals, and where very little care is required to procure shelter or clothing, agriculture has

made little progress; because it is comparatively unnecessary for the prosperity of the inhabitants. In climates of a directly opposite character, agriculture has made equally slight progress, from the natural obstacles opposed to it. In such countries, for example, as Greenland and Kamschatka, only one or two kinds of corn crops can be cultivated, and perennial grasses can scarcely exist, because the ground is covered with snow for eight months in the year: and in these countries agriculture is but little practised, as the chief resources of the inhabitants for food are found in the sea and the forest. In intermediate climates, such as those of the south of Britain, the middle of France, and the north of Italy, the soil admits of labour by man throughout the whole year; and there is scarcely any limit to the kind of crops that may be raised on it. In such climates, agriculture is calculated to attain the highest degree of perfection; and comparing the different parts of the zones with this description of climate in both hemispheres, we may perhaps assert that the best agriculture in the world is to be found in Britain, Belgium, and North Italy. The kind of agriculture practised in different countries is also of course adapted to the difference of climate. Thus, towards the north, the great art of the cultivator would consist in supplying heat; or, rather, in adopting such measures as would best guard plants and animals against cold, rains, and the vicissitudes of the weather. Towards the south, on the other hand, the art of the cultivator would be chiefly directed to moderating extreme heat, and supplying moisture. It thus appears that the agriculture of any country necessarily depends on its latitude; and that in high and low latitudes, where there are greater extremes of temperature and climate to contend with, agriculture must be of a more difficult and hazardous description than in intermediate or temperate climates, such as that of Syria, where the art is supposed to have originated, or in Europe, where it may be considered as having attained its highest degree of perfection.

In tracing the progress of this art in civilised countries, we have only to follow the chronology of general history. As the Greeks and Romans appear to have arrived at as great a degree of perfection in legislation as the moderns, so they appear to have attained nearly equal excellence in the practice of agriculture. Till within the present century very little difference existed between the most approved agriculture of climates analogous to that of Italy, and the agriculture of the Romans as described by *Jato*, *Columella*, and other ancient writers. The chief superiority of the moderns consists in their machinery, and in their knowledge of the science of the art; the last being of very recent date, and by no means general among practitioners. By science, improved breeds, both of plants and animals, have been originated; and by improved machinery, a more perfect tillage has been produced, and also a

AGRICULTURE

more complete separation of the produce from the soil, from the refuse of the plants and other impurities.

The history of agriculture in Britain begins with that of the Roman conquest. Julius Cæsar found the inhabitants in a state of semi-barbarism; but Agricola left them in possession of all the arts of civilisation then known. Agriculture declined with the invasion of the Saxons; but was preserved through the dark ages after the establishment of Christianity, by the intelligence of the members of the religious establishments, who gradually became possessed of the greater part of the landed property of the country. Agriculture revived in the reign of Henry VIII., and in that of Elizabeth, during the long period of peace which then prevailed, and the consequent security of property. It afterwards declined during the civil wars, but again revived during the reigns of William and Mary, Queen Anne, and George I., in consequence of the introduction of the Flemish husbandry, which included the culture of turnips and clover. A still greater stimulus to the art was given during the reign of George III. by the introduction of ploughs drawn by two horses, instead of four or six, of the drill system, and its application to the culture of turnips and potatoes; and by the improvement made in the breeding and rearing of live stock. Early in the present century, the threshing machine was an important addition to agricultural machinery; the reaping machine, the frequent drain system, and the subsoil plough, are improvements now coming into use; and the next grand step will be the general application of steam, instead of horses or cattle, to tillage and other field operations.

The literature of Agriculture commences with the works of the Romans, of which Columella's work, *De Re rustica*, may be considered the most comprehensive. In the dawn of modern agriculture, the principal writers were, Crescentius in Italy, Herrera in Spain, Olivier de Serres in France, Hereshbachius in Germany, and Fitzherbert in England. At the beginning of the present century the most comprehensive author on agriculture in Italy was Filippo Re; in France, Tessier; in Germany, Thayer; and in England, Marshall. The best work from which a general idea may be obtained of the agriculture of France and corresponding climates is, *Maison Rustique du dixième siècle; ou, Encyclopédie d'Agriculture pratique*, complete in one thick volume, 8vo.; and the corresponding works in Britain are London's *Encyclopædia of Agriculture*, Stephen's *Book of the Farm*, Morton's *Cyclopædia of Agriculture*, and Wilson's *British Farming*.

The theory of Agriculture is founded on a knowledge of the nature of plants and of animals, of soils and manures; and of the climate, the seasons, and the weather. Plants are organised beings, which take up their food, by roots from the soil, and by leaves from the air: animals are organised beings which select their food from vegetables growing on the surface

of the soil, or from other animals, and this food is prepared, before being absorbed into the system, by means of a stomach. The climate of a country determines both the plants and the animals which can be produced in it, while the seasons and the weather mark the time when the plants and animals of the given climate are in particular states of vigour or torpidity, and when certain operations of culture can be performed on them or on the soil.

The nature of the elementary materials being understood, even though imperfectly, certain improvements can be effected in them by art, which are greatly conducive to the increase of agricultural produce. The kinds of plants and animals suitable to any given climate, soil, or season, are determined by the laws of nature; but from among these kinds it is in the power of man to make a selection; and with the plants and animals so selected to originate others, adapted to his purposes in a superior degree. Hence the importance of selecting certain breeds of animals rather than others; and of making choice, not merely of one kind of bread-corn rather than another, but of particular varieties of that corn. Thus, in the case of wheat, there are some kinds the grains of which, under no circumstances, weigh more than sixty pounds a bushel; while there are others which never weigh less than sixty pounds a bushel. The nourishment of plants has been found to depend chiefly on inorganic matters contained in the soil, either originally present in it, or supplied by the decay of vegetable and animal matters. This is a law of nature, which, followed up by man, has led to the use of manures; just as the fact, everywhere observed, that no plant can live without water, has led to irrigation; and as the observation that the excess of water is injurious, has led to surface and under draining. The influence of temperature and shelter over the growth of plants and the thriving of animals, is everywhere observable in wild nature; and though the temperature of a climate cannot be changed, yet that of most localities may be improved by shelter from cold winds, and by diminishing the evaporation from the surface, by means of surface and under draining, to draw off the superfluous water. The most important principles in the theory of agriculture are those which relate to the improvement of plants and animals, and of the soil.

The improvement of the soil may be comprised under two heads—the improvement of its earthy part, and the increase of the fertilising matters added to this earth. The improvement of the soil, considered as a mixture of different earths, consists in rendering it more or less retentive of water, by diminishing or increasing the size of the particles of which it is composed: for example, by the addition of clay in some cases, and sand in others; and by improving the earthy composition of the soil by the addition of such earths as may be in too small quantities, or wanting altogether. It has

AGRICULTURE

been found, from experience, that those soils which are composed of several primitive earths are naturally more productive than such as consist of only one earth, all other circumstances being the same; and it has also been found that no soil will maintain its fertility for any length of time that does not contain a certain portion of calcareous earth in its composition. Hence one of the most common means of improving all soils not calcareous is, by the addition of lime; and of all other soils, by mixing them with such as are of an opposite description.

All soils whatever are rendered more productive by the addition of what are called *manures*. Manures may either be composed of animal or of vegetable matter, or of such mineral and inorganic substances as are found in the ash of plants. Organic manures may be applied either separately or mixed, and in a fresh state, or in a state of decay. It has been found from experience, and explained by chemical experiments, that they are ineffective until they undergo putrefactive fermentation; and this process is carried on either slowly in the land itself, or previous to application, with solid manure in heaps or dunghills, and with liquid manure in tanks or wells. In the application of manure to soils, the great object of the cultivator is to apply enough for the ensuing crop, and as little more as possible; because that which is applied and not immediately used is liable, to a certain extent, to have its particles carried off by evaporation into the atmosphere, or by rains into rivers or the sea. But, even if this were not the case, to apply manure to a soil where it would not be immediately turned into a crop, would be an expenditure of capital without interest.

The operation of freeing a soil from superfluous water is of equal or perhaps more importance than supplying it with manure; because, though without manure plants will not grow with great luxuriance and vigour, yet with too much water they will not grow at all, or will become sickly. The excess of water may proceed from three causes: an extremely moist climate; a soil very retentive of moisture, so as to hold it like a sponge; and, lastly, a soil lying over a subsoil which abounds in springs, or which has the substrata charged with water, which is continually oozing out through the surface soil. The remedy for this last evil is by under drains of considerable depth, so directed as to collect the water from the substrata, and carry it off before allowing it to reach the surface soil.

A soil, after being drained and rendered of a proper texture and composition by the admixture of such earthy ingredients as may be wanting, requires, both for the fertilising effect of atmospheric exposure, and to render it fit for being penetrated by the roots of plants, to be frequently stirred and comminuted. This is done by the mechanical operations of ploughing, harrowing, &c., which, aided by the alternate action of droughts and rains, frosts

and thaws, and summer and winter, have the effect of pulverising the soil. To maintain a soil in a fertile state, it is not only necessary to supply it with manure in proportion to the crops which have been carried from it, but to vary the crops which it is made to produce. It has been found from experience that crops of plants belonging to the same natural family do not succeed as well after each other, as when crops of a different family are made to intervene. Thus, the several grasses alternate better with root or herbage crops than with one another; or, one of those grasses of which the seed is ripened, will alternate better with another in which the herbage only constitutes the crop, than with one of the same kind as itself.

Thus, the *principles of Agriculture* may be comprised under the selection of breeds of plants and animals; the improvement of the soil and subsoil; the culture or movement of the soil; the improvement of the local climate by shelter and drying; and the succession of crops. All these principles have been derived from experience; and they are only in part accounted for by chemistry or natural philosophy. They are not, however, on that account, the less true and useful. It is singular that they should all have been known to the Romans, and, to all appearance, almost as fully so as they are to modern cultivators.

The *practice of Agriculture* in Britain may be included under the heads of the choice, hiring, and stocking of a farm; and its general culture and management. In the choice of a farm in any given country, the object of greatest importance is the nature of the soil; because, though this may be improved by art and expense to such a degree as almost to render a bad soil equal to a good one, yet in practice this would be so expensive as rarely to answer the purpose of the farmer. It may be thought that the vicinity of good roads, of a canal, a railroad, or a market-town, are objects of more importance than the nature of the soil; but this is not the case, because, supposing the roads to be bad, and the market at a distance, it is only necessary to change the system of cultivation and management, and to turn the produce of the farm into some description of live stock which may be driven to a distance, even over a country without roads. If it be alleged that the nature of the climate is of paramount importance to the soil in the choice of a farm, we allow that in an extended sense it is; for example, if a cultivator had the choice of any part of Europe, there are doubtless many districts where the climate is far more favourable for all the operations and products of agriculture than others; and even if he had the choice of every part of Britain, he would find some localities much more favourable than others. In general, however, the actual choice of any cultivator lies within a given locality, where the climate, in a practical point of view, is everywhere the same. Next to soil and climate in the choice of a farm, the state of

AGRICULTURE

the buildings and fences on it, the state of the roads, and the distance from a market-town, are of importance. Without buildings of a sufficient extent, properly situated, and of the proper kinds, the business of a farm cannot be carried on; and in general, fences are as necessary as roads. The last circumstance which we shall mention in this cursory glance is, the nature of the tenure by which the farm is to be held, and the covenants and conditions of the lease. No cultivator, who calculates on the employment of a considerable capital, will risk it on the lands of another without some security for having it returned; and this security is a lease for a fixed number of years. On the other hand, no proprietor of lands will delegate the possession of them to another for a fixed number of years, without a valuable consideration; and this he reserves to himself in the lease, under the denomination of rent. As lands in a state of cultivation, and buildings and fences in a state of repair, are liable to be injured and deteriorated in value by bad management or neglect, the proprietor guards against these accidents by certain conditions in the lease.

The kind of culture and management adopted in any farm depends jointly on the soil and climate; and on the kind of produce most in demand, or reckoned most profitable. In the mountainous districts of Great Britain, where the climate is cold, almost the only kind of farming practised is that of breeding and rearing different kinds of live stock; such as sheep or cattle, which are sold for being fattened in more favourable districts; or horses, in order to supply the demand for these animals for the purposes of draught or for the saddle. The mountainous districts of Scotland and Wales are chiefly devoted to the breeding and rearing of sheep and black cattle; which are sold to the farmers of the low country in both kingdoms, in order to be fattened for the shambles. The hilly districts of Yorkshire and Lancashire are chiefly employed in the breeding and rearing of horses. In the low country of the east coast of Great Britain, the climate, being dry, is favourable for the culture of corn; while on the west coast, and in Ireland generally, the climate, being moist, is more favourable for pasture. The farm products most universally in demand are corn and butcher's meat; and these may be produced on every farm the fields of which admit of being kept alternately in tillage and in grass. The butcher's meat may, however, be produced in much greater abundance on such soils as admit of the culture of root and herbage crops, such as turnips, potatoes, clover, &c.; while corn may be produced most abundantly in strong loamy soils, within reach of extensive sources of manure. The most profitable description of crop will frequently be found to be different from that which is most generally in demand: for example, in the neighbourhood of a large town, the culture of culinary vegetables on a large scale, in what are called farm-

gardens, is generally far more profitable than the raising of corn or butcher's meat. Even the raising of food for cattle in such situations is found to yield more profit than common farming. There are also particular crops which may be occasionally cultivated, which yield extraordinary profits; such as plants used in dyeing, or in some specific manufacture; plants of some new and improved variety of the kinds in general cultivation for their seed, &c.

A farm being fixed on, all preliminary matters settled, and the farmer in possession, his first business will be to fix on the general system of cultivation that he means to adopt. In this, as already observed, he will be guided by what the farm is capable of producing, and what he can dispose of. One of the first points that he will determine after this, will be the quantity of land that he can have under each particular kind of crop that he intends to grow; and next, the order in which these crops are to succeed one another. No point, indeed, in the whole system of farm management, is of more importance than the succession, or, as it is usually called, the rotation, of crops. The principle on which the succession of crops is founded has been already hinted at; and in here treating it practically, it may be sufficient to state, that all agricultural crops whatever may be reduced to three kinds—exhausting crops, restoring crops, and cleaning crops; and that the perfection of a rotation consists in always having an exhausting crop followed by a restoring or a cleaning crop; or, what is best, by both combined. All crops which are allowed to ripen their seeds, or which are carried wholly off the ground, are considered exhausting, though in different degrees. Thus, the most exhausting crops in general cultivation are those of corn; but clover, tares, or even hay cut green, are also exhausting, though in a much less degree. Restoring crops are those where the produce is suffered to decay on the ground, or is consumed on it; as in the case of pasture, crops of tares, turnips, &c. Cleaning crops are such as are grown in drills, sufficiently wide to admit of hoeing and other operations of cleaning between. Some of these are at once cleaning and exhausting, as where corn is sown in drills; while others are cleaning and restorative, such as where herbage plants, as clover and lucerne, or roots, as turnips, are drilled, and the plants are to be eaten off on the spot. Other principles which enter into consideration in fixing on a rotation of crops are, that plants which are nearly allied should not succeed each other; because, whether from exhausting the soil of one particular kind of nutriment, or by depositing in it one injurious kind of secretion, certain it is, that the same kind of plants cultivated without intermission on the same soil so become sickly. Thus three or four crops of any kind of corn in succession will not only unfit the soil for that variety or species of corn, but in a great measure for every other.

The farmer having determined on the crops which he is to grow, and the order of their succession, his next business is to calculate the quantity of *stocking* which will be required for his farm. By stocking is to be understood the number of horses, cattle, and other live stock; and the kind and number of machines, implements, and tools that will be required. In addition to these, he must take into calculation the number of male and female servants which it will be necessary for him to keep, either permanently by the year, or to hire occasionally by the week. Lastly, he will have to take into consideration the sum of money which he will require to lay out for servants' wages, house-keeping, rent, and all other expenses, before he receives any return from his farm produce. The sum total is the amount required for what is called stocking a farm; and it amounts, in different parts of the country, to from 6*l.* to 10*l.* per acre. Poor soil under pasture requires the smallest sum per acre; and rich soil under tillage the largest sum.

The farm being entered on, and the system of culture determined, the future business during the lease is one uniform routine of preparing, sowing, reaping, threshing, and marketing; including, where the breeding or fattening of live stock enters into the system, their purchase, fattening, and sale; or, their rearing, breeding, and sale.

The agriculture of Britain, and especially of the low country of Scotland and the eastern counties of England, excels that of most other countries having similar climates, from the superior skill, intelligence, and capital of the farmer; the considerable length of lease which is granted by the landlord, or the prevalence of a liberal tenant-right agreement; the superiority of the machines and implements employed; and the improved breeds of animals and plants which are reared or cultivated. Perhaps the nearest approach to perfection in the culture of arable land in any part of Britain, is made in some parts of East Lothian, where, in consequence of deep ploughing, substituting under-drains for furrows, regularly supplying manure, and alternating cleaning and restoring crops with exhausting crops, as great an amount of produce is obtained as can stand on the surface at one time. The agriculture of Britain is most defective in the southern and western districts of the island, and wherever the farmers are less wealthy and intelligent and less enterprising, owing to the want or the shortness of leases and to the restrictive clauses in those leases, by which the tenant is prevented from exercising his own judgement and is obliged to follow the routine prescribed in the leases of a former age. The adoption of so-called 'artificial' manuring; the large imports of guano and the enormous manufacture of superphosphate of lime; the extended use of steam power, not only in preparing crops for market, but in the tillage of the land; the adoption of the reaping machine and mower, and that of turnip cutters, chaff cutters, pulp-

ing machines, and steamers in the preparation of food for the live stock of the farm, have made a great change in the character of English agriculture since the publication of the first edition of this work.

Agrimonia (Lat.). A wild plant of the Rosaceous family, with saw-edged pinnated leaves, and a long spike of yellow flowers, followed by bur-like fruit. It has had the reputation of keeping old age away from those who persevere in the use of it in decoction. At least, it has the merit of being harmless, and from its slightly tonic qualities it would probably form a good kind of diet drink.

Agrionidae. The name of a family of Neuropterous insects, including the various kinds of dragon-flies (*Libellula* Linn.; see that word). The blue dragon-fly (*Agrion puella*) frequents the rushy sides of ditches, and is one of the commonest of the British species of this family.

Agrostemma (Gr. ἀγρός, a field, and στέμμα, a crown). The name of a few Caryophyllaceous plants, closely related to *Lychnis*, and distinguished by the elongated segments of the calyx-limb, by the absence of scales on the claw of the petals, and by the capsule opening by valves which alternate with the calyx segments. The corn cockle, *A. Githago*, is a representative species.

Agrostis (Gr.). A common genus of grasses, occurring on damp pastures, and dry waste ground. *A. alba*, the marsh bent grass, is the Florin grass of agriculturists. In this genus the flowers are single within the glumes.

Agrostology (Gr. ἀγροστis, a grass, and λόγος, a discourse). That part of botany which comprehends what relates to the grasses.

Agrypnia (Gr. ἀγρυπνία). In Medicine, the name applied to a state of watchfulness or restlessness.

Ague (Anglo-Sax. ege, shivering). An intermittent fever, which comes on at certain intervals, leaving the person in the intermediate periods in apparent health. The febrile attacks are often remarkably regular, whence the division of agues into quotidian, which are daily attacks; tertians, which appear every third day, having an intermission of forty-eight hours; and quartans, the intermission of which is about every seventy-two hours. The period during which the fever continues is called the paroxysm or pyrexial period; and the intermission, the apyrexial period. The febrile paroxysm consists of three stages, which follow each other in regular succession; namely, the cold, the hot, and the sweating stage: during the latter, the febrile symptoms abate and disappear.

Ague Cake. An enlargement of the liver or of the spleen produced by the ague.

Aguti. The Indian name of some South American herbivorous Rodent quadrupeds, now included in the genus *Dasyprocta*.

Ahriman, or Arimanius (East. theology). One of the chief deities of the ancient Persians. Their philosophers entertained the opinion

subsequently held by the Manicheans, that there were two principles, one of good and one of evil to the latter of which they gave the name of Ahriman. The two principles were not, however, supposed to be co-eternal or alike powerful; at least such was not the orthodox belief but it was supposed that in the end, the principle of good, Oromasdes, (Ahuromasda,) would finally prevail over and utterly destroy the principle of evil. (Bayle, arts. ARIMAN, MANICHEANS, and ZOROASTER; Milman, *History of Christianity*, book iii. ch. v.)

AI. A word which is a pretty close imitation of the plaintive cry of the three-toed sloth (*Acheus tridactylus* F. Cuv.), of which it is the trivial name.

Aich's Metal. An alloy of iron, copper and zinc, said to be greatly superior to gun-metal in tenacity and ductility. It is also called *Sterro Metal*.

Aid (Fr. aide, from Lat. *adjuvare*, to help). A pecuniary tribute paid by feudal vassals to their lords in certain cases of emergency. [FEUDAL SYSTEM.]

Aide-de-camp (Fr.). An officer appointed to attend a general officer in the field, in winter-quarters, and in garrison, to receive and carry orders. A field-marshal is entitled to four, a lieutenant-general to two, and a major-general to one. The king appoints as many as he pleases, and this situation gives the rank of colonel.

Aigrette (Fr.) in Botany. [PAPPUS.]

Aikinite. A mineralogical synonym for acicular bismuth. [NEEDLE-ORE.]

Air, Atmospheric (Gr. *ἀήρ*, air). The air which surrounds our globe to a height of about forty miles, and which is essential to all living beings, was one of the *elements* of the ancient philosophers: its weight and several of its mechanical properties were discovered by Galileo and Torricelli about the middle of the seventeenth century; but its composition was not accurately determined till more than a century afterwards.

The air is transparent, colourless, inodorous, and tasteless, essential to the respiration of animals and vegetables, and to the support of combustion. It is 816 times lighter than its bulk of water; 100 cubic inches, at mean temperature and pressure, weighing about 30·9 grains, according to Regnault.

The air is a mixture of nitrogen and oxygen gases, with a small portion of carbonic acid gas and of the vapour of water. In particular situations, other substances exist in it; as, over marshes, miasmata; over sulphureous springs, sulphuretted hydrogen; over and near the sea, in dry weather, muriatic acid, either free or combined; and a substance, probably of organic origin, which, aided by light, reddens solution of silver; peculiar organic combinations, sometimes infectious, where people, especially the sick, are confined; sulphurous acid and ammonia, in London and other places where large quantities of coal are burned; and traces of nitric acid during severe thunder

storms. A modified condition of oxygen, called *Ozone*, is also occasionally present.

The leading constituents of the air are nitrogen and oxygen, which are to each other in the relative bulks of about 79 and 21, or 80 and 20; and these proportions are probably not liable to any appreciable change, either dependent on season, wind, weather, situation, or height from the surface. Berthollet found 21 per cent. of oxygen in Cairo and in Paris; Saussure, the same in Geneva; De Martyr, in Catalonia, in all winds, weather, seasons, and states of the barometer, in wet and dry, and in inhabited and uninhabited places; Davy, in Bristol and other places in England and upon the coast; also in air brought from the coast of Guinea; Brande, in air from Behring's Straits and from Otaheite; Berger, in the Jura and in the mountains and valleys of Savoy; Confagliachi, on the Simplon and Mont Cenis (20·8 of oxygen over rice-fields); Gay Lussac and Humboldt, in Paris, in all seasons and weathers, and at 6,636 mètres above the surface, from 20·9 to 21·5; Dalton, in England, from 20·7 to 20·8; Selden, 21: on January 8, 1835, the barometer being 30·9 inches and a north-east wind, 21·15. In crowded and confined places, the relative proportion of oxygen may be a little below the proper standard, but is soon again restored. Air collected at the back of the upper gallery in Covent Garden Theatre, on a full night, gave 20 oxygen, and rendered lime-water more than usually turbid.

The relative proportion of carbonic acid is more variable; yet this gas is found in air from the most elevated regions and purest sources. Saussure and Beauvais found it on the top of Mont Blanc, and in the same proportion in the streets of Paris and at 650 oises above the city. At sea, carbonic acid as sometimes not been discoverable. Saussure found it vary with the seasons, and no doubt vegetation may affect it. In August, over a meadow, the air contained 0·000713, in January, 0·000425. Dalton estimates the mean proportion of carbonic acid at 1 in 1000; Confagliachi, the maximum at ·8, and Humboldt it from ·5 to 1·8: this is probably in excess.

The aqueous vapour is the most variable constituent of the atmosphere. It is more abundant with a south and west wind in summer and in warm weather, than with a north and east wind in winter and cold weather. In this climate it usually fluctuates between 1 and 1·5 per cent.

Dr. Prout, (*Bridgewater Treatise*, p. 350), has suggested the possibility of the occasional existence of extremely minute portions of deleterious matters in the air during the prevalence of epidemic disorders; and, in reference to this subject, a remarkable observation occurred during the prevalence of the cholera. For more than six weeks previous to the appearance of cholera in London, he had been almost every day engaged in accurately determining the weight of a given quantity of air under precisely the same circumstances of

AIR

temperature and pressure. On February 9, 1832, the sp. gr. of the air suddenly rose above the usual standard, and it continued so for six weeks. On February 9, the wind, which had been west, veered round to the east, and the first cases of epidemic cholera made their appearance.

Without reference to the occasional presence of foreign matters, the average ordinary constitution of the atmosphere may be stated as follows:

	By measure	By weight
Nitrogen . . .	77.50	75.55
Oxygen . . .	21.00	23.32
Aqueous vapour . . .	1.42	1.03
Carbonic acid . . .	0.08	0.10
	100.00	100.00

AIR. In Music, signifies the *melody*, or most prominent part of a musical composition. In part music it is generally the soprano, or treble. The word, or the Italian, 'Aria,' is also used for a song, or piece for a solo voice.

AIR. In Painting, the medium in nature through which every object is viewed, and hence to be transferred to the imitation on canvass. The effects which it produces are an indispensable part of the knowledge of every artist. It affects the sizes and colour of objects according to their distance.

AIR-BLADDER. An organ situated in the abdomen of most osseous fishes, which, by altering its dimensions, and the quantity or density of its contents, regulates their relative position to the surface of the water, and is supposed to represent the rudimental condition of the lungs of the higher vertebrates.

AIR-CELLS. In Botany, cavities in the stems and leaves of plants, constructed of cellular tissue, and rendering the part in which they reside buoyant in water.

AIR-CELLS. In birds, are membranous receptacles communicating with the lungs, eight of which, of large size, occupy the interspaces of the thoracic and abdominal viscera; the smaller ones extend around the principal joints of the four extremities, penetrate the substance of the bones, insinuate themselves between the skin and subjacent muscles, and enter the quills of the feathers, so that the whole body of the bird is permeated by the atmosphere; whereby its specific gravity is diminished, its respiration extended, its circulation accelerated, and its muscular energies increased, and thus it is finally adapted to wing its way through aerial space. In the flying insects the air-vessels are more or less dilated into air-cells at different parts of their course, in order to diminish the specific gravity of the general mass of the body.

AIR-GUN. An instrument for projecting bullets or other missiles, the moving power being the elastic force of condensed air. A strong vessel of metal is constructed, into which air is forced by means of a condensing syringe. The air vessel may be of any form, but it is most conveniently disposed of by placing it within

AIR-PUMP

the stock. The bullet is placed near the breech, and should fit the barrel very exactly, so as to leave no windage. On pulling the trigger the condensed air escapes through the valve, and rushes with violence into the barrel, propelling the bullet before it; and the instant the finger is withdrawn from the trigger the valve is closed by the pressure of the air in the magazine, which remains in a somewhat less condensed state for the next discharge. Thus the same supply of air in the magazine will serve for several successive discharges, but the force becomes weaker and weaker after each. The force with which a projectile is propelled from an air-gun is much less than that produced by an ordinary charge of gunpowder.

Air-plants. A name given to plants of any kind which grow without their roots penetrating the earth. They have been so called, from its being supposed that they derive their nourishment exclusively from the atmosphere; but as they are usually found in places where they are in contact with at least minute quantities of vegetable matter, or even with the juices of the plants upon which they grow, it is probable that their existence is in part maintained much in the same way as that of other plants. The most extensive natural order in which air-plants are found is *Orchidaceæ*, hundreds of species of which literally crowd the forests of some of the damp and hot parts of the world. Next to these range Bromeliaceous plants, some of which will live for months suspended freely in the air, or tied to iron or stone balconies. Various species of *Ficus*, and some *Gesneraceæ*, have similar habits.

Air-pump. A pneumatic machine for removing the air out of a vessel. The principle of this instrument is very simple. The essential part of the machine consists of an exhausting syringe (*a*), closed at one end with the exception of an orifice, to which a valve (*b*), opening inwards, is attached. An air-tight piston is worked up and down in the barrel by a rack and pinion turned by a winch. The piston has also an orifice with a valve (*c*) which opens upwards, or in the same direction as the valve of the barrel. The syringe communicates, by means of a pipe (*d*), with a vessel (*e*) called the receiver, from which the air is to be extracted.

The receiver is placed on a brass plate (*f, g*), and in order that the contact may be air-tight, its ground edge is previously rubbed with a little pomatum.

Suppose the piston at the bottom of the tube. As it begins to be drawn up, the valve *c* of the piston is immediately shut by the pressure of the exterior atmosphere, so that no air can enter the barrel, and a perfect vacuum would be left under it, were it not that the valve at the bottom of the barrel is forced open by the pressure of the air in the receiver, which rushes into the barrel till its density becomes the same

both in the receiver and barrel. When the piston has been drawn to the top of the barrel, the whole of the air which occupied the barrel has been removed, and the receiver and barrel are now both filled with the air which was previously contained in the receiver alone.

Suppose the capacity of the receiver to be six times that of the barrel, the air which at first occupied six measures now occupies seven, and is consequently reduced to $\frac{6}{7}$ ths of its former density. Let the piston now be returned to its first position. The instant it begins to descend, the valve *b* shuts, so that no air can enter the receiver. As soon as the piston has descended through one-seventh of the barrel, the air in the barrel is restored to the density of the exterior atmosphere; and as it descends further, the air in the interior of the barrel is condensed, till it acquires an elasticity sufficient to open the valve *c* in the piston, when it rushes out, and continues to do so till the piston has quite returned to the bottom of the barrel. Thus by one stroke of the piston the density of the air in the interior of the receiver is reduced to $\frac{6}{7}$ ths of its previous density; and it is evident that each succeeding stroke will produce the same effect, or remove $\frac{1}{7}$ th part of the remaining air. Consequently, after the second stroke, the density of the air in the vessel will be reduced to $\frac{6}{7}$ ths of $\frac{6}{7}$ ths = $\frac{36}{49}$ ths of the exterior air; after the third stroke it will be reduced to $\frac{6}{7}$ ths of $\frac{36}{49}$ ths = $\frac{216}{343}$ ths, and so on. After twenty-one strokes, it will be reduced to about $\frac{1}{25}$ th of its first density; after one hundred strokes, to $\frac{1}{5,000,000}$ th part. But so high a degree of rarefaction cannot in practice be obtained; for as soon as the elasticity of the air in the receiver is reduced so far that it has not sufficient force to lift the valves, no more air can escape from the receiver into the tube, and the exhaustion cannot be carried further.

What has now been said applies to all air-pumps, though the form of construction admits of great variety. The better sorts have two exhausting barrels, and the pistons are worked by a rack and pinion, so that when the one piston is ascending in the barrel, the other is descending, by which means an uninterrupted discharge of the air is kept up. The receiver is placed on a smooth plate of brass, having a small hole in the middle to receive the end of a pipe communicating with the syringe. Various contrivances have been employed to continue the exhaustion after the air has been rarefied to that degree that it does not retain sufficient elasticity to lift the valves. In order to determine the degree to which the rarefaction is carried, a barometric tube is adapted to the machine, the upper end of which communicates with the receiver, while the lower end is plunged into an open basin of quicksilver. As the receiver is exhausted, the air is withdrawn from the tube at the same time, and the external air presses up the mercury in the tube to a height proportional to the degree of rarefaction.

This is called a *gauge*; but the following form is more frequently employed. A tube six or eight inches in length, sealed at one end and filled with mercury, is inserted in a basin of the same liquid. The mercury is of course supported by the pressure of the atmosphere, and continues to fill the tube. This apparatus is placed beneath a second receiver, communicating with the pipe *d*. During the first stages of the exhaustion, the mercury still remains supported; but so soon as the tension of the contained air becomes less than is sufficient to support the column of mercury, the liquid begins to fall, and the height at which it stands above the level of that in the basin is the measure of the tension of the remaining air. This is called the short Barometer Gauge.

Otto Guericke, a magistrate of Magdeburg, was the first who conceived the idea of rarefying the air in a vessel by means of a pump, about the year 1654. The machine which he constructed was of a very rude kind, but it enabled him to exhibit experiments which at that time were regarded as astonishing. The air-pump was afterwards greatly improved by Hooke and Boyle; and has attained its present state of perfection through the successive inventions of Hawksbee, Smeaton, Cuthbertson, and others.

Air-vessels. In plants, are minute tubes composed of an exceedingly fine transparent membrane, closed at each end, and furnished internally with a delicate elastic thread twisted spirally, whence they are now commonly called spiral vessels. They occur in the medullary sheath, the veins of leaves and of flowers, in the stamens, the ovary, and the seed: their office is to convey air. In the genus *Nepenthes* spiral vessels are found in the bark and wood in vast quantities.

Air-vessels. In insects the atmospheric air is conveyed through all parts of the body, for the purposes of respiration, chiefly by means of air-vessels, or *tracheæ* (which see).

Aisle (Lat. *ala*, a wing). In Architecture, a term used by the English more especially to signify the side divisions of a church, which are usually separated from the nave or centre portion by pillars or columns. In Egyptian architecture, the Romans denoted by this term the side walls of temples. In that of the Greeks, the *ptera* (a name answering to the Latin *alæ*), were the rows of columns ranged along the sides of temples. The monopteral temples were always circular, the outer wall forming a continuous pedestal for the columns. These buildings had no cella. The peripteral had one row of columns round the cella, the dipteral two; the pseudo-dipteral differed from the peripteral or hexastyle temples in having the side columns moved outwards over the space of one column and intercolumniation, and so had eight columns at each end. The term is also applied to the sides of a building which are subordinate to the principal or central division, and are vulgarly called 'wings.'

Aits or Eyots (A.-Sax. *cy, an island*). *given to the finest varieties of massive granular Islets, commonly planted with osiers, and which are then called willow aits.* Gypsum or sulphate of lime, which bear the same relation to other kinds of Gypsum that marble does to ordinary limestones. The purer kinds are made into statuettes, vases and other ornamental articles, and the commoner sort is converted, by burning, into plaster of Paris. The snow-white translucent Alabaster found at Volterra and Castellina, in Tuscany, is largely manufactured in Florence into works of art, which are exported to all parts of Europe. The alabaster of this country is chiefly met with in the New Red, or Keuper Marl, principally at Ashton-on-Trent, and Chellaston Hill, in Derbyshire, where it is largely worked for ornamental purposes. It is also found in large quantities in Glamorganshire, at Penarth, and other places; at Newark, in Nottinghamshire; Fauld Hill, Tutbury, and near Burton-on-Trent, in Staffordshire; Syston in Leicestershire; Old Chine in Somerset; between Penrith and Carlisle, in Cumberland; and in Monaghan Co., Ireland. [SATIN SPAR.]

Akenium. [ACRINIUM.]

Akshivan. [TANTALUS.]

Al Araf (Arab. *arafa, to distinguish*). In Mohammedan Theology, mentioned in the Koran, a kind of limbo, or place of sojourn for those departed spirits which are received neither into Hell nor Paradise.

Ala (Lat. *a wing*). A Roman military term, signifying the wing of an army: but its meaning varied at different times. Denoting at first the body of horsemen who served with the foot soldiers, when the whole legion consisted of Roman citizens, it was applied, after the admission of Socii, whether Latini or Italici, to the troops of the allies, both horse and foot, which were stationed on the wings. At a still later time, the ala were composed of foreign troops serving with the Roman armies, while under the empire the term was applied to bodies of horsemen raised generally in the provinces and serving apart from the legion.

ALA. In Entomology, the wings, or organs of aerial progression, are tegumentary productions simply, and consist of a double membrane of a tender and generally transparent consistence, inclosing numerous nervures, or branched tubes of a firmer substance.

These organs present considerable differences of form and structure in the different orders of insects, and also vary in number from two to four.

ALA. In Ornithology, the pectoral extremity, the bones of which support broad folds of skin, covered with feathers, and are adapted for flight. The under part of the base of the wing, where it joins the body, is termed the *axilla*; the joint between the antibrachium and carpus is termed the flexure or *plica*. The wing is said to be armed (*ala calcarata*) when the carpus bears one or two horny spurs; to be impennate (*ala impennata*) when provided with equal, lax plumes, unfit for flight; to be elongate (*ala elongata*) when, in the folded state, it equals or exceeds in length the body from the base of the bill to the root of the tail; to be middle-sized (*ala mediocris*) when, in the folded state, the extremity covers the base of the tail; to be short (*ala brevis*) when, in the folded state, the extremity reaches the sides of the coccyx.

Alabandine. The name Alabandine was given by Pliny to the Ethiopian Carbuncles which were cut and polished at Alabanda. By modern mineralogists the name is used as a synonym for Manganblende, or Manganeseglance.

Alabarches (Gr). This name was apparently given to the chief magistrate of the Jews at Alexandria, whose duties lay chiefly in raising and paying the taxes. The word is of very doubtful origin, and many have proposed to substitute the word Arabarches in every place where it occurs. (Smith, *Dictionary of Greek and Roman Antiquities*, s. v.)

Alabaster (Gr. *ἀλβαστρος*). The name

Albite. A mineralogical synonym of Augite and Diopside.

Alamire. In Music, the name of one of the notes in the modern scale of Guido. [Music.]

Alangiacœæ (Alangi, the Malabar name of one species). A natural order of plants closely akin to *Myrtacœæ*. It consists of Indian species, with aromatic roots and eatable fruit. Their long strap-shaped petals afford one of the principal distinctions between them and the *Myrtaceæ* order.

Alanin. A white crystalline substance derived from aldehyd-ammonia, and hydrocyanic acid. Hyponitrous acid converts it into lactic acid.

Alantino. An amylaceous substance extracted from the root of the *Angelica archangelica*.

Alaria (Lat. *ala, a wing*). A genus of sea-weeds found in the colder regions of the North Atlantic and Pacific Oceans. One species, *A. esculenta*, the badderlocks or henware, is found on our own coasts, and is one of the best of the esculent *Algæ*, its midrib and fruit-bearing appendages being the parts most freely used. The name badderlock has been supposed to be a corruption of balderlocks, or locks of Balder, a Scandinavian deity.

Alate (Lat. *alatus, winged*). In Botany, when any solid body is bordered by a membranous or leafy expansion.

Alda (Lat. *a lark*). The name of a Linnæan genus of passerine birds, characterised by the claw of their hinder toe, which is straight, strong, and longer than the others. The birds of this genus are granivorous, and nidificate on the ground. The field-lark (*Alda arvensis* L.) is a well-known example: they appertain to the conirostral division of the passerine order of Cuvier.

Alb (Lat. *albus, white*). A vestment, worn by priests in the Roman Catholic church, which differs from the surplice in fitting more closely

to the body, and being tied with a girdle; it is also commonly embroidered on the breast with crosses.

Albarium Opus (Lat.). In ancient Roman Architecture, this term was supposed by some critics to mean nothing but a species of whitewash, but in the passage of the fifth book of Vitruvius, chap. x., where he recommends the use of the *albarium opus* for the ceilings of baths, he allows *tectorium opus* to be used as a substitute for it, so that it was clearly a species of stucco. Its employment at the baths of Agrippa, knowing as we do the extent to which luxury was carried in the baths of the ancients, seems to prove that it was a superior sort of stucco, and it is by no means improbable that it was susceptible of polish. This opinion is pronounced by Perrault, in his translation of Vitruvius.

Albata (Lat.). The name of a white metallic alloy of brass, with tin or nickel, and sometimes iron. It is largely manufactured at Birmingham, and worked into spoons, forks, dishes, teapots, &c.

Albati (Lat.). Christian hermits, so called from the white linen they wore. They lived and slept in the highways. (Hook, *Church Dictionary*, s. v.)

Albatross. [DIOMEDEA.]

Albert Coal, or Albertite. A variety of bituminous coal, found at the Albert Mine, Hillsborough Co., New Brunswick. It is of a brilliant and lustrous jet-black, very compact and extremely brittle, breaking with a conchoidal fracture. A thin seam of Albertite has lately been discovered near Mountgerald, in Ross-shire, in strata of Old Red Sandstone age.

Albigenses. (From Alby, a town in the south of France.) A sect which arose in the south of France in the latter half of the twelfth century. They have been confounded with the Waldenses, with whom, however, they do not appear to have had any real connection. Their tenets have been very differently described, and probably misrepresented, by their opponents; and great obscurity is thrown upon the subject, by the fact of the appearance of various dissenters from the church of Rome in England and elsewhere, about the same time, whose respective views have not been very accurately discriminated. It is probable that the reformers of the south of France opposed themselves originally to the corruptions in discipline, which began first at that period to draw general attention and animadversion upon the clerical order. Hence a very easy step would lead them to think slightly of many ecclesiastical ordinances, and the ceremonial observances of religion would seduce them into the adoption of mystical notions about an internal light and assurance, and finally betray them into the wildest extravagancies. Thus they are charged with perpetuating the Manichean doctrines; but Bossuet, who accuses them of inclining to that system on certain points, acquits them of holding what is, after all, the distinguishing

tenet of the Oriental heresy—the monstrous doctrine of the two principles.

In the year 1163, Alexander III. published a decree against these sectarians in a council held at Tours, and another in 1179. On neither occasion, however, did he invoke the assistance of the secular arm. At the close of the century, when the sect was still flourishing, and seemed to be more particularly under the protection of Raymond, count of Toulouse, Innocent III. commenced the work of its extirpation. He appointed two legates to go through the country and excite the zeal of the clergy and laity against the innovators: he instituted the Dominican order of friars, purposely to preach them down; and finally, in 1207, he addressed himself to Philip Augustus, king of France, exhorting him to eradicate the heresy with the sword. The contest or ‘crusade,’ which was carried on with more or less vigour for many years, and which furnishes the first evidence of the disposition of the church of Rome to employ extreme violence against those who dissented from its doctrines, ended in the entire destruction of the Albigenses, about the middle of the thirteenth century. (Sismondi, *Hist. des Français*, tom. vi.; Milman, *Latin Christianity*, Book ix. ch. 8; Hallam, *Middle Ages*, Part I. ch. i., and Part II. ch. ix.)

Albin. A white opaque variety of Apophyllite, found at Aussig, in Bohemia.

Albinism. A state in which the skin is white, the hair flaxen, and the iris pink. [ALBINO.]

Albino. A term originally applied by the Portuguese to negroes who were born mottled or disfigured with white spots. It is now generally applied to persons of a preternatural whiteness of the skin and hair, with a peculiar redness of the pupil of the eye, which is so weak as to be of little use in broad daylight, so that albinos sleep in the daytime, and are only capable of seeing distinctly in the twilight or by moonlight. The disease appears to depend upon a deficiency or morbid state of the *rete mucosum* over the whole body. Albino races are frequently observed in domestic animals, e. g. in the cat, rabbit, &c. The ferret (*Putorius furo*) is an albino variety of the polecat (*Putorius fætidus*).

Albite (Lat. *albus*, white). Soda Felspar. A silicate of alumina and soda, in which a small portion of the soda is sometimes replaced by potash and lime. It generally occurs in flat twin-crystals, which vary from translucent to opaque, and are usually white, but sometimes green or brown. It is found in Cornwall, in Ireland, and in the granite of Slieve Corra (one of the Mourne mountains) it is met with in very perfect white translucent twin-crystals. The principal foreign localities are the Tyrol, St. Gotthard, Arendal in Norway, Greenland, Siberia, Sweden, Bohemia, Oisans in Dauphny, Massachusetts, &c. Albite is frequently a constituent of granite, and (as in the rocks round Edinburgh) of syenite and

ALBUGO

greenstone. When it occurs associated with common Felspar in the same granite, it may be distinguished from the latter by its greater whiteness and translucency.

Albugo (Lat.). A disease of the eye, consisting of a white speck in the cornea.

Album (Lat.). Literally means anything white. The term is now generally applied to a book in which persons collect autographs, literary essays, &c. The prator's album was a white board, on which the edicts of that functionary were inscribed.

Album Græcum (Lat.). When dogs are fed upon bones, they digest the animal portion, and the earthy parts (chiefly phosphate of lime) are voided in the form of white excrement. This inert matter was formerly used in medicine under the above title.

Albumen. A peculiar organic principle, entering largely into the composition of animal bodies, such as the blood, muscles, membranes, and most of the soft organs, such as the liver, lungs, kidneys, &c.; also the chief component of white of egg, to which the term albumen was originally applied, and which well and familiarly illustrates its leading peculiarity, namely, that at a certain temperature it coagulates into a soft white solid, no longer soluble in water. It may be obtained pure by coagulating the white of egg by alcohol, washing it thoroughly with that fluid, and then carefully drying it at 120°. It then appears as a yellow, shining, transparent and brittle substance, composed of—

Nitrogen . . .	1 atom	=	14	15.05
Carbon . . .	8	=	48	51.61
Hydrogen . . .	7	=	7	7.53
Oxygen . . .	3	=	24	25.81
	1		93	100.00

The albumen of birds' eggs (ovalbumen) coagulates at a temperature of 145° to 165°; and when dried, shrinks and becomes brittle and semitransparent, in all respects resembling horn. One hundred parts of the albumen of the hen's egg lose, upon careful drying, about 86 of water, and leave 34 of solid residue. Alcohol, most of the acids, and several metallic salts, also coagulate albumen, and some of the latter are very delicate tests of its presence in animal fluids: subacetate of lead, for instance, renders a solution of 1 part of fresh white of egg in 2000 of water turbid, so that it detects 1 part of dry albumen in 10,000 of water. Corrosive sublimate is also an excellent test of albumen, forming with it a white insoluble compound; hence white of egg has been proposed as an antidote in cases of poisoning by corrosive sublimate. Albumen is a proximate principle of many vegetables, found in their sap and in some of their solid products.

ALBUMEN. In Botany, a floury, fleshy, bony, or horny substance secreted in some seeds between the embryo and the seed-skin. It is intended for the nutriment of the young embryo when it first springs into life. The part

ALCARAZZA

that furnishes the flour of corn, the flesh of the cocoa-nut, the great mass of the seeds of coffee, are albumen. Botanists have remarked that this substance is never deleterious, however poisonous the plant may be by which it is borne.

Albumum (Lat. *sap-wood*). The newly formed and soft part of the wood of Exogenous trees, consisting of empty or nearly empty tubes and colls, the sides of which are thin and not indurated; however durable the timber of a plant may be, this part of it is in all cases perishable, the vegetable matter of which it consists having but little power of adhesion, and being readily decomposed by the action of the air. It is only when the tissue of this part becomes consolidated by the addition of resins, tannin, and various other products, which change its colour from a pale yellow to various other deeper colours, that timber really becomes valuable. In some species this is effected rapidly, as in oak, teak, lignum vitæ, &c.; in others, very slowly, or not at all, as in the poplar and willow. Hence the wood of the latter class of trees never acquires any durability. By some writers the albumum is defined to be 'wood only one year old.' But this is erroneous. It is through the albumum principally that the ascending sap of a plant moves; the course of the sap is not, however, confined to the albumum, but is effected wherever the woody tubes are sufficiently open for it to pass.

Alca. The name of a Linnæan genus of Anserine birds, characterised by a short, compressed, vertically extended, convex beak, edged along the upper surface, and generally transversely furrowed; feet toti-palmate, and wanting the hinder toe. Recent ornithologists have divided the Linnæan auks or penguins into the subgenera *Fratercula* and *Alca*.

Alcabala, or Alcauala. A tax formerly imposed in Spain and her colonies, consisting originally of 10, and subsequently of 14 per cent. ad valorem, on all property sold, and payable as often as it changed hands. This monstrous impost, by preventing the sale and transfer of property, necessarily proved in the highest degree injurious.

Alcalde, or Alcaide. A Spanish officer of justice; from the Arabic *kadî*, *judge*. In Portugal, *Alcayde*.

Alcalimeter. A graduated glass tube employed in determining the quantity of real alkali in commercial potash and soda, by the quantity of dilute sulphuric acid of a known strength which a certain weight of these saturates.

Alcamphora. A Brazilian herb, the *Croton perdicipes*, whose leaves are used in decoction against syphilis, and as a diuretic.

Alcantara. ORDER OF: otherwise called the order of Saint Julian, or of the Pear-tree. An order of knighthood, instituted in 1156 at Alcantara, a town of Estramadura, by Hadrian II. king of Leon. The king of Spain is sovereign of this order.

Alcarazza. A porous vessel used in Spain

ALCARSIN

for cooling water by its transudation and consequent superficial evaporation.

Alcarsin. *Cadet's fuming liquor* or *oxide of cacodyl*. A horribly fetid liquid formed when acetate of potash and arsenious acid are heated together. It is volatile and intensely poisonous.

Alcedo (Lat.). The name of a Linnæan genus of Piceæ, characterised by a long, straight, angular and pointed beak; the tongue and tail very short. The feet have the structure which is the basis of Temminck's order Syndactyli, viz. the external toe is nearly as long as the middle one, and is united thereto as far as the penultimate articulation. The kingfisher, *Alcedo ispida*, a familiar example of that genus. The *Alcedo tridactyla*, and some others, are remarkable for the absence of the inner toe; these have accordingly been separated from the Linnæan genus under the sub-generic term *Coryx*. A third subgenus, *Dacelo*, receives the careful laughing kingfisher of New Holland.

Alchemy. An imaginary art, once much practised among modern nations, and even now perhaps not wholly exploded. The name is a mixture of Greek and Arabic; the last syllables being from the same root with *chemistry*. The prefix is the Arabic article *al*, *the*. Whether alchemy was followed as an art among the classical ancients, seems questionable: some suppose it to have originated among the Arabs of the Califfate. Its object was the production of gold and silver. The principle of the alchemists was, that certain of the baser metals were convertible into these two precious substances by a long series of processes. To this fundamental notion the common followers of the art added an infinity of fantastic imaginations respecting the influence of the planets, &c., in hastening or retarding the work. The instrument by which it was supposed that this mighty change was to be effected, was a certain mineral to be produced by these processes, which, being mixed with the base metal, would transmute it; and this was called the *lapis philosophorum* or philosopher's stone. Hence the term *adæpt* (adeptus) for him who was supposed to have attained the secret of alchemy; or, in other words, gained or discovered the philosopher's stone. Innumerable instances are on record of persons who practised on the credulity of former times by professing to possess this stone, and who actually wrought the transmutation required; and it is supposed that the philosopher's stone employed by these personages was nothing more than an amalgam of gold, which, if projected into tin and cupellated, would leave a portion of the precious metal. Dr. Prieß, of Guildford, is said to have been the last person in this country who professed himself able to turn mercury into gold: he destroyed himself in 1782, to avoid, it was supposed, the detection of his deceptions. The alchemists, in the course of their endless experiments, are said to have served the cause of true science in many ways. To various adepts is ascribed the discovery of the concentrated acids and of phosphorus. Another object of

ALCOHOL

the adepts, often pursued by them, together with their research after transmutation, was the discovery of the *elixir vite*, or supposed universal medicine. Alchemy is also denominated the Hermetic Art, from the imaginary sage, Hermes Trismegistus.

Alcohol or **Alkohol**, a term of Arabic origin, implying a spirit or essence in its most perfect state. It is retained in modern chemistry to signify pure spirit of wine. Fermented liquors were known in the earliest ages. The Northern nations were probably acquainted with the art of obtaining ardent spirits before the Greeks or Romans. Albucasis in the twelfth century taught the method of procuring alcohol from wine, and Raymond Lully in the thirteenth century concentrated spirit of wine by carbonate of potash.

The elementary composition of alcohol was first accurately demonstrated by Lavoisier, and its analysis was perfected by Saussure. It consists of—

			Per cent.
Carbon . . .	4 atoms =	24	52.18
Hydrogen . .	6	= 6	13.04
Oxygen . . .	2	= 16	34.78
		46	100.00

It may also be regarded as the hydrate of oxide of ethyle, and in that case represented by the rational formula $C_4H_{10}O.HO$. [EUKK.]

Pure alcohol has never been frozen; hence its value in the construction of thermometers for measuring temperatures below the freezing point of mercury. It burns with a pale flame, producing carbonic acid and water, and without smoke or soot, forming a cleanly and useful lamp, giving much heat, but little light. It boils at 176° , and the density of its vapour is to that of air as 1.6 to 1.0. Alcohol has an agreeable odour, a strong pungent taste, and is a powerful excitant. The specific gravity of *absolute alcohol* is 0.793 at 60° ; that of the *rectified spirit* of commerce is about 0.838, and contains about 16 per cent. of water. What is called *Proof Spirit* has a specific gravity of 0.920, and consists of about 49 parts by weight of absolute alcohol and 51 of water; or by measure of 54 parts of alcohol and 46 of water. When alcohol and water are mixed heat is evolved and condensation ensues, and it is some hours before the two liquids perfectly combine, so as to attain their maximum density.

The strength, or alcoholic value of spirituous liquors, is inferred from their specific gravity, which, for fiscal purposes, is determined by the hydrometer. The following table shows the percentage of alcohol in such mixtures; and in the *Philosophical Transactions* for 1797 will be found an elaborate series of tables founded upon the experiments of Mr. Gilpin and Sir Charles Blagden. Abstracts of these and other similar tables are also given in Ure's *Dictionary of Arts, Manufactures, and Mines*, art. 'Alcohol.' [FERMENTATION; METHYLATED SPIRIT; WINE.]

ALCOHOLATES

Sps. Gr. at 60°	Per cent- age of real Alcohol	Sps. Gr. at 60°	Per cent- age of real Alcohol	Sps. Gr. at 60°

9028	33	8793	67		

Alcoholates. Salts in which alcohol appears to replace the water of crystallisation.

Alcoholmeter. An instrument by which the quantity of alcohol contained in wines and other spirituous liquors is determined by reference to their respective boiling points at given pressures.

Alcohols. Substances resembling common vinic alcohol in constitution; chemically speaking they are hydrated oxides of organic radicals.

Alcoran or Alkoran (Al Koran, or *the Book*, Arabic). The sacred book of the Mohammedans; which, according to their belief, was dictated to their prophet by the angel Gabriel. The Koran consists of 114 chapters; which are distinguished, not by their numerical order, but by certain titles, under which they are respectively known. Every chapter is divided into smaller portions, analogous to the verses of our Scriptures. There are, however, seven principal ancient copies of the Koran; and in all of these the number of verses is not the same. The Koran is written in what may be termed a species of chiming or jingling prose. It is regarded among the Mohammedans as in itself a standing miracle, and a proof of the truth of their religion; and hence the division between those who believe the Koran to be eternal and uncreated (the Sunnites or orthodox), and various sects of heretics.

Alcornine. A crystallizable substance contained in the alcornoko bark of America.

Alcove (Span. *Alcoba*). In Architecture that part of a sleeping chamber where the bed is placed. In Modern Architecture, the alcoves

ALDINE EDITIONS

introduced differ greatly in their manner of decoration, according to the rank or the taste of the proprietor: in England they are rarely used; in France and in Italy they frequently form imposing objects in the decoration of palaces. Generally speaking the alcoves are raised slightly above the floors of the bed rooms, and are roofed at a lower level than that of the latter; they are sometimes separated from the room by a balustrade, through which drapery is passed.

Alcyonites. A collective term for the fruit-like spongiform flint fossils common in chalk formations.

Alcyonium. A Linnean term for an aggregate genus of marine polypes, having a fleshy coriaceous spicular axis, beset with stellate cells, containing each a polype with eight radiate denticulate arms. The axis is fixed to foreign bodies, and in some species rises in short branches or lobes, as in that commonly known by the name of 'Dead Man's Hand.' (*Alcyonium digitatum* Lin.; *Lobularia digitata* Lam.)

Alcyons (Gr. ἀλκυών, *a kingfisher*). The name given by Temminck to an order of birds of which the kingfisher (*Alcedo*) is the type.

Aldebaran. In Astronomy, the Arabic name of a large and bright star of the first magnitude, called the 'Bull's Eye,' and in catalogues α Tauri, in the eye of the constellation Taurus.

Aldehyde (from *alcohol dehydrogenatus*). A pungent volatile liquid, obtained by distilling alcohol with oxide of manganese and sulphuric acid. Alcohol is a compound of 4 atoms of carbon, 6 of hydrogen, and 2 of oxygen; whereas aldehyde consists of 4 of carbon, 4 of hydrogen, and 2 of oxygen.

Alder (Anglo-Saxon *alp*). A native tree (*Alnus glutinosa*) belonging to the natural order *Betulaceæ*. It is chiefly found in damp situations, and is of little value except for hurdle wood, and for the manufacture of charcoal.

Alderman. Originally written *ealdor-man*, meaning elder-man, which was used in the earlier parts of the Saxon period as a name of dignity unconnected with office; it was also the original title of the officer who was subsequently styled earl, whence counties were sometimes called alderman-shires. It seems also to have been the designation of the chief magistrate or judicial functionary of minor districts, in which sense it first appears in connection with boroughs. Its application is now confined to the class of municipal officers in a borough next in order to the mayor. By 5 & 6 W. 4, c. 76, the aldermen are to be in number one-third of the councillors in every borough (London alone being excepted from the provisions of the act), one part to be elected triennially, on November 9, from among councillors or persons qualified to be such; and to form, with the mayor and councillors, the council of the borough.

Aldine Editions. In Bibliography, those which issued from the press of the three

Manutii. Aldo Manuzio was born at Bassiano in the Papal States, and studied in Rome and Florence. He contracted an intimacy with Pico, Count of Mirandola, and with Alberto Pio, Lord of Carpi; and with their assistance set up a printing press at Venice, in 1490. Being a man of great learning and extraordinary zeal in his new profession, he laboured to procure the most correct MSS. of the Greek and Latin classics, and established an academy in his house with the view of obtaining the cooperation of the learned in the superintendence of his works through the press. Bembo and Navagero were among his coadjutors. His first work appeared some time in 1490, but his first dated work in 1494. He was the author of a Greek grammar, a Greek and Latin dictionary (the first of its kind), and many other works. His books have always been prized more for their correctness than for their typographical beauty. They were mostly printed in the duodecimo form. A very rare catalogue of his labours was printed in Venice in 1653 (*Catalog. Librorum Ald.*), and reprinted in Paris in 1709. A complete list is also given in Renouard's *Annales de l'Imprimerie des Aldes, ou Histoire des trois Manieres et de leurs éditions*, Paris, 1803, 2 tom. 8vo., the last edition of which appeared in 1834. The invention of what are now called *italic* types is due to Aldo, who first made use of them in his *Virgil*, printed in 1501. Having observed the many inconveniences resulting from the vast number of abbreviations then in use amongst printers—to such an extent indeed as to render the publication of a treatise on the art of reading a printed book necessary—he hit upon the expedient of using thin italic type, avoiding abbreviations and causing little increase in bulk. These types were for some years afterwards called *Aldine*, but by the Italians themselves *corsivi*. Aldo's son Paolo, a man of learning, an author and a critic, succeeded him in his printing establishment. The family press is said to have been broken up in 1597, although some Venetian publications of the beginning of the seventeenth century are in existence bearing the impress of their colophon (an anchor and dolphin) on the last page.

Ale. [BEER.]

Ale-conners, or-kenners. Those who *ken* or *know* good ale. Ale-conners were annually chosen by the court-leet, and sworn to look at the assize and goodness of the ale and beer in their lordships.

Alectorides (Gr. ἀλεκτωρ, *a cock*). A tribe of rasorial or gallinaceous birds, including the curassow, and the species which, like it, resemble the common fowl in the form of the beak.

Alembic (from the Arabic particle *al*, *the*, and *ambeeg*, corrupted from the Greek word ἀμύξα, *a cup or vessel*). An obsolete form of still: constructed upon a small scale in glass, it is sometimes used in the laboratory.

Alembroth, or Salt of Wisdom. A term

applied by the old chemists to a salt composed of sal ammoniac and corrosive sublimate. It is poisonous.

Alexandrian School. An academy for literature and learning of all kinds, instituted at Alexandria by Ptolemy, son of Lagus, and supported by his successors. The grammarians and mathematicians of this school were particularly celebrated. In the former class occur the noted names of Aristarchus, Harpocration, and Aristophanes; and among the latter were numbered the astronomer Ptolemy and geometer Euclid. The grammarians of Alexandria exercised a universal literary jurisdiction, publishing canons of those who were to be considered standard authors, and revised editions of ancient writers. For some account of the famous collection of books at Alexandria, see LIBRARY.

Alexandrine. The French heroic verse of twelve syllables or six iambic feet. In English poetry it is occasionally used: by Dryden, sometimes as a second line in a heroic couplet, more frequently as a third line in a triplet; and the Spenserian stanza necessarily concludes with an Alexandrine. The lines of Pope, defining the Alexandrine by an example, are well known:

A needless Alexandrine ends the song,
Which, like a wounded snake, drags its slow length
along.

Alexandrite. A variety of Chrysoberyl found in mica-slate, with Beryl and Phenacite, near Ekatherinenberg in the Ural. It was named after Alexander I., emperor of Russia.

Alexipharmic (Gr. ἀλεξιφάρμακος, from ἀλέξω, *I avert*, and φάρμακον, *a poison*). In Medicine, a term applied to things which serve as antidotes to poisons.

Alexiterics (Gr. ἀλέξω, *I avert*). Preservatives against contagious and infectious diseases, and the effects of poisons in general.

Algæ (Lat. *algæ*, *sea-weed*). Plants which are destitute of all signs of sexual organs, and which vegetate exclusively under water. When they grow in salt water they are called sea-weeds, when in fresh water they are named Confervæ. They comprehend, in the division *Zoospermææ*, some of the lowest known forms of vegetable life, plants consisting of simple cells adhering in different degrees, and emitting at maturity spores or seeds having a distinct motion. In the case of *Oscillatorias*, the whole mass of the plant writhes and twists spontaneously; and the *Zygnemææ* actually copulate. It is in this part of the vegetable kingdom that plants approximate to animals in the most striking degree. A general sketch of this group of plants may be found in Berkeley's *Introduction to Cryptogamic Botany*; an excellent account of the salt-water species in reville's *Algæ Britannica*, and Harvey's *Phycologia Britannica*; and of the fresh-water kinds in such books as the *English Flora*.

Algaroba (Arab. *al*, *the*, and *garoba*, *a bean-tree*). A leguminaceous tree found in the southern parts of Europe, and in Palestine,

ALGAROTH, POWDER OF

having pods filled with a sweetish nutritious powder: they are supposed to have been the locusts on which St. John fed in the wilderness. It is the *Ceratonia Siliqua* of botanists. In sandy deserts it is invaluable, because of its roots piercing the soil to such a depth as to be always in contact with water, the effect of which is to maintain perpetual verdure.

Algaroth, Powder of. The white powder which falls when chloride of antimony is dropped into water: it is a compound of chloride and oxide of antimony, virulently purgative and emetic. Named from Algarotti, its discoverer.

Algebra. An important branch of Mathematics, whose name appears to be a contraction of the Arabic phrase *Al jebr e al mokabalah*, the English equivalent of which would be *restoration and reduction*. It is sometimes called a universal arithmetic, but may be more appropriately described as a calculus of symbols. The symbols it employs are of three kinds: (1) those of quantity, known or unknown, which consist of ordinary numbers and letters of the alphabet; (2) those of operation, amongst which are +, -, ×, ÷, √, &c.; and (3) mere abbreviations for ordinary words. [SIGN.] The combination of these symbols according to fixed laws leads to algebraical expressions or formulæ, in which actual computations are indicated rather than performed. The universality of algebra as compared with arithmetic consists in the fact that, in the latter, computations being effected as they arise, all traces of the intermediate steps are obliterated, and the result is applicable to a single case only; whereas, in algebra, the formulæ contain implicitly the answers to an unlimited number of questions. Again, to the equivalence of two algebraical formulæ always corresponds a general theorem, which arithmetic can only *verify* in particular cases. Thus, from the algebraical identity

$$(a + b)(a - b) = a^2 - b^2,$$

we learn that 'the product of the sum and difference of any two numbers is equal to the difference of their squares.'

The systematic notation, to which algebra owes its chief power as an instrument of research, has been of very gradual growth, and is still being extended. In the first known treatise on the subject, by Diophantus, who probably lived in about the fourth century of our era, the few symbols employed are mere abbreviations for ordinary words. The Arabians, who obtained their algebra from the Hindoos, did little or nothing towards its extension, though their treatises, after being carried into Italy by a merchant of Pisa, Leonardo Bonacci (1202 A.D.), gave rise to important improvements. Scipio Ferreus, of Bononia, is said to have solved the first problem of the third degree (1606); but it was Tartaglia, or rather Cardan, who first gave the general solution of a cubic equation, and employed letters to denote the unknown quantities.

ALGODONITE

the *given* ones being still mere numbers. Without extending algebraic notation, Ferrari, a disciple of Cardan, discovered the general solution of a biquadratic equation, and thus, unknown to himself, reached the barrier which, as has since been proved, will ever remain impassable to the searcher for *general* solutions of equations of the fifth and higher degrees. [EQUATION.] Towards the middle of the sixteenth century, algebra was introduced into Germany, France, and England, by Stifelius, Peletarius, and Robert Recorde, respectively. In doing so, our countryman introduced the very convenient symbol of abbreviation =, and Stifelius the far more important symbols of operation +, -, √. In the same century, through her far-famed son Vieta, France contributed still more to the progress of the science. Vieta introduced letters as symbols for known as well as for unknown quantities, and by the increased power thus acquired he laid the foundation of the general theory of equations. In this direction he was followed by Girard, Harriot, Descartes, and others; in short, the science now advanced rapidly towards its present state of perfection. It would be fruitless here to attempt to trace its progress. The reader who wishes to do so may consult with advantage Hutton's *Mathematical Tracts*, vol. ii., Bonycastle's translation of Bossuet's *Histoire des Mathématiques*, or the *History of Mathematics* by Montucla. The last great improvement in algebraic notation, that of determinants, is of quite recent date. [DETERMINANT.]

Algebraic. An expression or equation is said to be algebraic when it consists of a finite number of terms, each of which involves only the operations of addition, subtraction, multiplication, division, and extraction of *given* roots. Expressions; on the other hand, which contain infinite series or quantities, such as $\log. x$, a^x , $\sin. x$, &c., although, strictly speaking, also algebraic, are distinguished by the term *transcendental*.

Algebraic Curve. A curve whose equation is algebraic. [CURVE.]

Algebraic Geometry. The application of algebra to geometrical investigations. The miscalled *analytical geometry*, whose founder was Descartes, and the characteristic feature of which is the determination of a point by means of coordinates, whose magnitudes are represented by algebraical symbols, is a kind of algebraic geometry, though not the only one. Coordinate geometry would be a more distinctive name for Descartes' invention.

Algerite. An altered variety of Scapolite, found in yellowish to greyish slender square prisms, imbedded in Calc Spar, at Franklin, in New Jersey. Named after Alger, the American mineralogist.

Algodonite. A native compound of arsenic and copper, composed of 83.66 per cent. of copper and 16.34 of arsenic. It is of a brilliant silver-white colour when first found, but it soon tarnishes on exposure to the air. It is met with in small white lumps and veins in the

ALGORITHM

silver-mine of Algodos, near Coquimbo, in Chili.

Algorithm (an Arabic word, compounded of *al*, *the*, and the Greek *ἀριθμος*, number). The art of computing in reference to particular subject, or in some particular way; as the algorithm of numbers; the algorithm of the differential calculus, &c.

Alguazil (Arab.). A Spanish officer, answering to the English bailiff. His duty is now confined to the apprehension of criminals, but he was in ancient times executioner also.

Alias (Lat. *otherwise*). In Law, when a defendant sued on a specialty, or a prisoner had more than one common appellation, he was designated in the Latin forms of instruments as 'A. alias dictus B.' When it is necessary for a second writ of the same description with a former one to issue, it is headed 'alias,' as, *alias capias*, &c.

Alibi (Lat. *elsewhere*). A cant Law phrase, used to express the species of defence set up by one charged with a criminal offence, who offers evidence to prove that he was elsewhere at the time when the act was committed.

Alidade. An Arabic name given to the index or ruler which moves about the centre of strolach quadrant, carrying the sights or telescope, and showing on the limb of the instrument the number of degrees and minutes during which the object observed is elevated above the horizon.

Alien (Lat. *alienus*, *foreign*). Generally speaking, is one born in a country out of the allegiance of the sovereign, unless his father were a natural-born subject, in which case he will himself be deemed a natural-born subject to all intents and purposes. By 7 & 8 V. c. 66, various statutory disabilities by which aliens were incapacitated from possessing property in England were mitigated; and they are now enabled, on memorialising the home secretary and taking a prescribed oath, to acquire nearly all the rights of natural-born subjects, with the exception that they cannot become members of the privy council, of either house of parliament, or of a municipal corporation. The 10 & 11 V. c. 83, relates to aliens in the British colonies. [DENIZEN.] **ALIEN PRIORIES** were inferior monasteries in England, belonging to foreign abbeys.

Alien Waters. Any stream of water carried across an irrigated field or meadow, but which is not used for the purposes of irrigation; or any waters which are carried through other properties without being made subservient to their uses.

Alienation. In Law, the act of parting with property, more especially real property. The alienation of real property takes place usually by deed. [REAL PROPERTY.]

Alignment (Fr. *alignement*). A Naval term for a supposed line drawn to preserve a fleet in position.

Alimentary Canal. A cavity in the interior of an animal body in which the nutriment is taken to be digested, before it is conveyed

ALKALI

by the nutritive vessels to the system: it affords the best organic characteristic of an animal, but presents various modifications of structure. Sometimes it is a simple cavity with one opening; sometimes a true canal with an outlet or anus, distinct from the inlet or mouth; this canal may be divided into stomach and intestine, as in the oyster; or a mouth, pharynx, and œsophagus may precede the stomach; the œsophagus, again, may have one or two sacculi appended to it, called crops. The stomach may be subdivided into four bags, as in the Ruminants, or into seven, as in the bottle-nose whale; and the intestines into small, blind, and large, forming, with their subdivisions, what are termed duodenum, jejunum, ileum, cæcum, colon, and rectum. The cæcum, again, may be single, or double as in most birds; or a single cæcum may exist in addition to a double one, as in the Hyrax, a small Pachydermatous quadruped. Lastly, the various glandular organs which communicate with the alimentary canal are to be regarded as cæcal processes of that tube, since these are developed from it, and in this condition they are permanently retained by one or other of the lower animals: thus, in the sea mouse, the liver is represented by long, branched, lateral processes of the intestine; in the cod fish, &c., the pancreas is similarly represented by numerous cæcal processes of the duodenum.

Alimony (Lat. *alimonium*, *sustenance*). In Law, the allowance for which a married woman is entitled to sue on separation from her husband. [MARRIAGE.]

Aliquot Part. A number which divides a given number without leaving a remainder; in other words, a *measure* or *divisor*. Thus, 2, 3, 4, and 6 are aliquot parts of 12, being contained in the latter 6, 4, 3, and 2 times exactly. The term is principally employed in the arithmetical rule of practice. [PRACTICE.]

Alismaceæ (from the Greek *ἄλισμα*). A small natural order of Endogenous plants, marked by the presence of numerous distinct carpels in a tripetaloidous flower. They form a near approach to the *Ranunculaceæ* among Exogens. *Alisma* and *Sagittaria* are the most common genera.

Alisonite. A double sulphide of copper and lead, composed of 53·34 per cent. of copper, 28·88 lead, and 17·78 sulphur. It occurs massive at Mina Grande, near Coquimbo, in Chili, of a deep indigo-blue colour, which quickly tarnishes on exposure. Named after R. E. Alison.

Ali-truncæ, Alitruncus. In Entomology, the posterior segment of the thorax of an insect to which the abdomen is affixed, and which bears the legs, properly so called, or the two posterior pairs, and the wings.

Alizarine. From Ali-zari, the commercial name of madder in the Levant; a peculiar colouring principle obtained from madder.

Alkalest. A term of Arabic origin, applied by the alchemists to a supposed universal solvent.

Alkali, or **Alcali**. Derived from the

ALKALI, FOSSIL.

Arabic article *al*, and *kali*, the name of a plant in the same language. A term originally applied to the ashes of plants, now generally used to designate potash, soda, and ammonia, which are also termed vegetable, mineral, and volatile alkali. These substances have certain properties in common, such as neutralising and forming salts with the acids, reddening several vegetable yellows, and changing some blues to green, and ready solubility in water. Lime, baryta, strontia, and magnesia, have been called alkaline earths, from their analogous action on vegetable colours. Lithia is also one of the alkalis. A singular class of bodies have been discovered in vegetables, which have been termed *alkaloids*, chiefly in consequence of their power of saturating and forming definite salts with the acids. Morphia, quinia, &c., are substances of this description.

Alkali, Fossil or Mineral. [SODA.]

Alkali, Phlogisticated. [FERROCYANIDE OF POTASSIUM.]

Alkali, Vegetable. [POTASH.]

Alkali, Volatile. [AMMONIA.]

Alkalimetry. The process of measuring or estimating the amount of alkali in a specimen of carbonate or caustic potash, or soda, of unknown strength. It is generally accomplished by exactly neutralising such a quantity of pure and dry carbonate of soda as contains exactly one hundred grains of real alkali, with diluted oil of vitriol. A volume of the acid, equal to that used in the experiment, is then farther diluted till it fills a tall narrow glass cylinder divided into one hundred parts. A large quantity of acid being thus prepared, one part or measure of which is equal to one grain of real alkali, it follows that the number of measures of acid used in exactly neutralising one hundred grains of impure carbonate of soda will be the number of grains of real alkali in that crude specimen. The standard acid once prepared, this process of determining percentage values is a very ready one.

Alkaloids. Substances analogous to alkaline bases, but of vegetable origin, and generally possessed of great medicinal activity. Their ultimate elements are carbon, hydrogen, oxygen, and nitrogen. The principal substances of this class, together with the plants from which they are obtained, are the following:—

Aconita	Aconitum napellus
Aricina	A bark from Arica
Atropia	Atropa belladonna
Brucia	Strychnos nux vomica
Cinchonia	Cinchona lancifolia
Coclea	Opium
Conia	Conium maculatum
Corydalia	Corydalis tuberosa
Cynapia	Æthusa cynapium
Datura	Datura stramonium
Delphia	Delphinium staphisagria
Digitaria	Digitalis purpurea
Emetina	Cephaelis ipecacuanha
Hycosyama	Hycosyamus niger
Meconia	Opium
Morphia	Opium

ALLANTOIS

Narcotina	Opium
Nicotina	Nicotiana tabacum
Picrotoxia	Menispermum cocculus
Quinia	Cinchona cordifolia
Sanguinaria	Sanguinaria canadensis
Solanina	Solanum nigrum
Strychnia	Strychnos nux vomica
Thebaia and Narceia	Opium
Veratria	Veratrum sabadilla.

Alkanet (a corruption of the French *orcanette*). A reddish-purple dye, obtained from the roots of *Anchusa tinctoria*. The root of this plant, which is a native of the warmer parts of Europe, contains a red resinous colouring matter which it imparts to alcohol and oils: it is used to tinge some ointments, especially lip-salves, of a red colour.

Alkarsino. A compound of carbon, hydrogen, oxygen, and arsenic; it was formerly called *Cadet's fuming liquor of arsenic*; it is the oxide of *kakodyle* of modern chemistry. [KAKODYLE.]

Alkermes. An old pharmaceutical preparation coloured with kermes, resembling the modern *aromatic confection*.

Alkool. A preparation of antimony used by the women of eastern nations to tinge the eyelids and lashes of a black colour. Dr. Shaw, speaking of the women in Barbary, says, 'None of these consider themselves dressed till they have tinged the edges of their eyelids with alkool.'

Alla Breve (Ital. according to the breve). In Music, the name of a movement each of whose bars or measures consists of the note called a breve, equal therefore to two semi-breves or four minims. It is denoted at the beginning of a staff by a C with a bar drawn through it vertically: thus, C.

Alla Capella (Ital.). In Music, the same as **ALLA BREVE**. The name originates in the circumstance of this time having been principally employed for movements used in the church or chapel.

Allagite (Gr. ἀλλαγή, *change*). A variety of Rhodonite, of a greenish-grey colour, verging upon black, found in the vicinity of Rubeland in the Harz. The name is in allusion to the change of colour which it undergoes on exposure.

Allah. The Arabic name of the Supreme Being. It signifies the True God, as opposed to the deities of idolaters.

Allanite. A silico-ferrous oxide of Cerium and Lanthanum, named after the late Mr. Allan, of Edinburgh, by whom it was first recognised as a distinct species.

Allantoic Acid. A white crystallizable acid, obtained by evaporating the allantoic liquid of the foetal calf.

Allantoine. The substance originally termed *Allantoic acid*. It has been produced artificially by the action of peroxide of lead on uric acid: its formula is $C_4H_5O_5N_3$.

Allantois (Gr. ἀλλὰς, *a sausage*, and *ἔμος*, *form*). A thin membranous sac developed from the termination of the alimentary canal

ALLANTURIC ACID

of the embryo, situated between the amnion and chorion, and organised by the hypogastric arteries and umbilical vein. Its function, as a temporary respiratory organ, is of most importance in those oviparous Vertebrates where the embryo has no branchiæ; in the Mammalia, its use is more or less superseded by the chorion and placenta. In some quadrupeds the allantois has the form of a sausage; whence its name.

Allanturic Acid. A product of the action of heat on allantoin.

Alleghanies. The part of the Appalachian chain of Eastern North America which crosses Virginia and Pennsylvania. The chain is 150 miles long, and includes several very narrow ridges of moderate elevation between which are narrow valleys. The parallelism of the ridges and valleys is very remarkable and characteristic. [APPALACHIAN CHAIN.]

Allegiance (Fr. *allégeance*, from the Latin *alligare*, to bind). The obedience which a citizen owes to his prince or country. The allegiance of a born subject of the English crown is inseparable, and follows him everywhere: nor can he by any act of his own free himself from it. There is also a temporary allegiance, which foreigners incur so long as they reside within the king's dominions. By common law, all persons above the age of twelve years were required to take the oath of allegiance at the court leet; and the oaths of allegiance and supremacy have since been imposed by many statutes. The present form of the oath of allegiance was introduced by the Convention Parliament of 1688. A single oath was substituted for those of allegiance, supremacy, and abjuration, in 1868, by 21 & 22 Vict. c. 48. The American laws require a foreigner to have renounced (as far as possible by his own act) allegiance to his former government two years before he takes the oath of allegiance to that of his acquired country.

Allegory (Gr. *ἀλληγορία*). In Rhetoric and Literature, has been defined, 'a figurative representation, in which the signs (words or forms) signify something beyond their literal or direct meaning.' In this sense allegory may be addressed to the eye, in painting and sculpture, by means of forms intended to convey, besides the notion of those sensible objects which they represent, certain abstract ideas to which these objects are supposed to bear analogy. Allegory differs, 1. from symbolical writing or representation; because in the first, the type and antitype, or thing exhibited and thing intended, have some real or natural resemblance, relation, or analogy: in the latter, the resemblance is merely conventional. Thus, to take an instance from modern literature: if it be true, as is now alleged, that the earlier Italian poets of the middle ages, and Dante in particular, attached a conventional meaning to certain ideas frequently recurring in their poems; as, for example, that Satan signified the papal power,—the three beasts mentioned in the commencement of Dante's poem three

ALLIANCE

states—love, loyalty to the emperor, &c. &c.; then their poems, considered with reference to this occult sense, must be regarded as specimens not of allegory but of symbolical writing. But if, as in the more ordinary interpretation of Dante's poem, Satan represents the abstract idea of eternal misery, the beasts particular vices, &c., which in common acceptation are supposed to have some natural analogy with their representatives, the poem is in this respect to be regarded as an allegory. Thus, also, critics have endeavoured to give a symbolical sense to the sixth book of Virgil's *Æneid*; while, independently of that sense, if it really exist, there is an obvious allegorical meaning running through the whole. (In ancient criticism, however, the words allegory and symbol were not so accurately distinguished; and in our translation of the Bible, St. Paul is made to use the word allegory in the clear sense of type, Gal. iv. 24.) Allegory differs, 2, from parable, only inasmuch as the latter is a species of the former; a parable being a short sententious allegorical narration. And, 3, it is different from metaphor, being in effect a chain of metaphors, or a single metaphor continued and wrought out into a lengthened discourse. 4. Fables may also be mentioned as a species of allegory. [FABLE.] An allegory, or allegorical tale, in the somewhat narrower sense in which the term is used in literature, is generally a tale in which abstract ideas are personified: such (to cite one of the earliest instances of this species of composition) as the *Choice of Hercules*, between virtue and vice, in the shape of two females: an allegory which descends to us from the Athenian sophist Prodicus. Entire poems are sometimes strictly allegorical, as that of Spenser; or entire narratives, as Bunyan's *Pilgrim's Progress*; in which case it requires consummate art to keep up the propriety of the allegory, which is in fact a compound of two opposite, and sometimes scarcely compatible, qualities—consistency running through its several incidents, when considered merely as a narrative and without reference to the ulterior meaning, and consistency of analogy between the thing represented and the thing indicated.

Allegretto, and **Allegro** (Ital. *a little merry*, and *merry*). In Music, the first term is a diminutive of the second, which, prefixed to a movement, signifies that it is to be performed in a brisk and lively manner; not, however, with hurry or precipitation. [TEMPO.]

Allemontite. A mineralogical synonym for the arsenical antimony found at Allemont in Dauphny.

All-hallows. The old English name for All Saints' day (the 1st of November).

Alliaceous Plants. Plants which partake more or less of the qualities of garlic and onions; such as onions, shallots, rocambole, chives, leeks, garlic, &c.

Alliance. In Politics and International Law, a league between two or more friendly powers; which may be either offensive and

ALLIGATION

defensive, or defensive only. Of the former species is the alliance of 1813 against Napoleon, subsequently called the Holy Alliance; and that of 1854 between England, France, and Turkey, against Russia; of the latter, the Quadruple Alliance, concluded in 1833 between England, France, Spain, and Portugal. Alliances are divided by publicists into three classes: 1. Those in which the allied parties agree to prosecute a war with their whole force. 2. Alliances in which auxiliary states pledge themselves to grant to a principal state a fixed contingent of men, money, &c. 3. Such as are constituted by treaties to furnish troops for stated subsidies, to make advances of money, &c.

Alligation (Lat. *alligatio*, from *alligo*, *I bind together*). A rule of Arithmetic, for the solution of questions concerning the compounding or mixing together of different ingredients, or ingredients of different qualities. There are two cases, one of which is alligation *medial*, and the other alligation *alternate*. To the first case belongs a question of this sort: Suppose 4 gallons of wine, at 12s. per gallon, to be mixed with 6 gallons at 17s. per gallon, what is the worth of a gallon of the mixture? But if it were asked, in what proportions wines, at 17s. and at 12s. per gallon respectively, must be mixed in order that the value of a gallon of the mixture may be 15s., the question would belong to alligation *alternate*. Questions of this kind are most easily resolved by algebra; they belong, in fact, to a class of indeterminate problems, admitting in general of an indefinite number of solutions. [INDETERMINATE ANALYSIS.]

Alligator (a corruption of the Portuguese word 'lagarto,' which is derived from *lacerta*, a lizard). In modern Zoology, the term is limited to those species of crocodile which have a wide obtuse muzzle, unequal teeth, the fourth pair of which, counting backwards in the lower jaw, pass into corresponding cavities in the upper jaw, where their points are concealed when the mouth is closed. In the true crocodiles, the corresponding teeth pass into open grooves in the margin of the upper jaw, and are consequently exposed. In the alligators the head is less oblong, its length being generally to its breadth as 3 to 2: the teeth are more numerous than in the crocodiles, sometimes amounting to twenty-two in the lower jaw, and to twenty in the upper. The hind legs and feet are rounded, and have neither crests nor dentations; the interspaces of the toes are only occupied for half their extent by a short membrane. The alligators, so far as is yet known, are peculiar to the New World.

Alliteration. In Composition, the frequent recurrence of the same letter, chiefly at the commencement of different words. This is sometimes resorted to, especially in poetry, for the production of effect. In the Celtic languages, alliteration was a recognised ornament in versification: it was so likewise in the early Gothic tongues; and in old English there are entire poems composed in alliterative metre, of

ALLOPATHY

which the celebrated *Vision of Piers Ploughman* is the most remarkable. The use of it did not wholly disappear until the middle of the 16th century.

Allituroic Acid. One of the bodies formed when alloxan is boiled with hydrochloric acid.

Allium (Lat.) A genus of Liliaceous plants, consisting for the most part of bulbous-stemmed species, and including the onion, *A. cepa*, leek, *A. Porrum*, garlic, *A. sativum*, shallot, *A. ascalonicum*, chives, *A. Schanoprasum*, and other onion-flavoured plants cultivated as condiments. It comprises numerous species, some of which are sufficiently ornamental to be cultivated for the sake of their flowers. They may be known amongst Endogenous plants by their odour. Of the species employed in medicine, the leek, the onion, and the garlic, the latter is the most active, as it is the most strongly flavoured.

Allocation. In Law, the allowance of an account in the Exchequer. The writ *de allocatione faciendi* is for allowing an accountant sums expended by him in his office. The certificate of allowance of costs of taxation granted by the master, prothonotary, or other officer of court, is termed in practice an *allocation*.

Allochroite. A massive variety of Iron-garnet, which derives its name (Gr. *ἄλλος*, another, *χρῶμα*, colour) from the various colours it exhibits when melted before the blowpipe with phosphate of soda.

Allocution (Lat. *allocutio*). A name given to certain addresses made by the pope to the cardinals.

Allodium. In Feudal Law, a word of uncertain derivation (see Wedgwood's *Dictionary of English Etymology*, s. v.; Hallam's *Middle Ages*, ch. ii. part i. note k). Land held by an individual in his own absolute right, discharged of all feudal obligation; opposed, therefore, to fee, fief, or feud. No allodial property can exist in England, where the king, in the eye of the law, is lord paramount of all lands and hereditaments. In ancient France the rule was, 'nulle terre sans seigneur,' and the presumption was in some parts of that country always in favour of a fief, unless the land were shown to be allodial. In Germany, on the contrary, the legal presumption was in favour of the allodium.

Allomerism. Constancy of crystalline form under variation in proportion of the constituents of a crystalline compound. Thus, an alloy of zinc and antimony containing 36 per cent. of the latter metal crystallizes in needles which do not vary in angular measurement, though the antimony be increased 20 per cent.

Allomorphite (Gr. *ἄλλος*, other, and *μορφή*, form). A variety of sulphate of baryta found in scaly masses near Rudoldstadt, in Schwarzburg.

Allopathy (Gr. *ἄλλος*, different, and *πάθος*, disease). A term recently invented to describe the ordinary system of medical practice in opposition to *Homoeopathy* [which see].

ALLOPHANE

Allophane (Gr. *ἀλλοφανής*, from *ἄλλος*, *other*, and *φαῖνμα*, *to seem*). A hydrated silicate of alumina, composed of 21·22 per cent. of silica, 40·39 alumina, and 35·39 water. It usually occurs lining small cavities and forming veins in marl or chalk; sometimes in little reniform masses with a resinous or waxy lustre, and of a pale blue colour, but occasionally green, brown, yellow, or colourless; translucent, and very brittle. It is found in the chalk-pits at New Charlton, near Woolwich, and abundantly in the chalk of Beauvais, in France; also in Saxony, Moravia, Bohemia, &c. The name has reference to its change of appearance before the blowpipe.

Allophanic Acid. An acid formed by passing the vapour of cyanic acid into alcohol: its chemical formula is $C_2H_3O_2N_2$.

Allotment of Lands. Any piece of land set apart or allotted for any particular purpose. When more land is laid to a cottage than suffices for a garden, it is commonly called a cottage allotment.

Allotropy (Gr. *ἀλλοτροπία*, *to be changeable*). A term used to designate the property (belonging to certain substances) of exhibiting variable characters at different temperatures, especially as relates to *colour*, *texture*, *solubility*, &c.: thus sulphur is usually yellow and brittle; but if fused at a high temperature, and poured into water, it becomes brown and viscid. The characters of phosphorus are also remarkably changed by temperature.

Alloxan. One of the products of the action of nitric acid on uric acid: it is a colourless crystalline substance, the aqueous solution of which tinges the cuticle purple: its chemical formula is $C_8H_4O_{10}N_2$.

Alloxanic Acid. A substance derived from alloxan by the action of caustic baryta and heat.

Alloy (from the French *à loi*, *according to law*, i.e. the law by which the composition of money is governed). The name given to the compounds of the more precious metals with others of less value; or to the less valuable of the metals in such compounds; thus, gold is said to be alloyed with silver, silver to be alloyed with copper. Chemists apply the term to all combinations obtained by fusing together metals: thus, brass is an alloy of copper and zinc; bronze, of copper and tin: when mercury is employed, the result is called an *amalgam*. Many of the alloys are extensively used in the arts, for they present characteristics which the pure metals do not possess; as, for instance, gold and silver, in their pure state, are too soft and flexible to allow of their being worked into plate, jewels, coin, &c., until they are hardened by the presence of a certain portion of copper, whilst their colour and other valuable properties are not materially impaired by the addition.

It has been found that the alloys of some metals present anomalous conditions, as for instance that they are greater, or less, than the mean of their compounds in specific gravity:

ALMACANTAR

indicating that in some cases they have expanded, and in others contracted. Their fusion point may also be greater or less than that of their mean composition; and it is at all times difficult to secure a mass which is of the same composition throughout. Some of the alloys are crystallizable, and are probably definite or atomic.

Allspice. The immature berry of Jamaica pepper (*Myrtus pimenta*). It has the combined flavour of nutmeg, cinnamon, and clove.

Alluandite. A hydrated double phosphate of soda, protoxide of manganese, and peroxide of iron, found in France, at Chanteloupe, near Limoges, in subtranslucent and opaque masses of a clove-brown colour. Named after M. Alluand.

Allusion (Lat. *adlusio*, from *ad*, *to*, and *ludo*, *I play*). In Rhetoric, strictly, a covert indication, as by means of a metaphor, a play of words, &c., of something not openly mentioned, and extrinsic to the principal meaning of the sentence.

Alluvial Deposit. A deposit of river-mud or silt. The term is generally limited to mud or silt conveyed by the ordinary current of a river from higher land to a plain, and there left behind, owing to diminished rate of motion of the water.

The remains of land animals of various kinds common on the banks of streams, and the leaves and twigs of plants growing in such localities, are often preserved in these deposits.

Alluvium. (Lat.) The mud or silt washed from the surface of land by rain into the ordinary streams of a country, and conveyed by them to the plains, where it is quietly deposited. Alluvium is a word used in contradistinction to *diluvium* [which see]. There is no limit to the age of alluvium, but we are only familiar with deposits of this kind recently made.

The literal meaning of alluvium (from the Latin *alluo*, to wash upon, or *alluvio*, an inundation) would refer to a limitation to those materials deposited on land not permanently submerged but merely washed over by water. This limitation is not always strictly adhered to, as the bed of a large river must be regarded as permanently submerged, and is yet composed of alluvial mud.

Allyle (Lat. *allium*, *garlic*). A hydrocarbon (C_3H_4) supposed to constitute the basis of the volatile oil of garlic.

Almagest. A name given by the Arabs to the celebrated work of Ptolemy, the astronomer of Alexandria: it signifies the greatest work, from the Arabic *al*, *the*, and the Greek *μέγιστος*, *greatest*. The best edition of this work is that of Paris, 1813-15, two vols. 4to., Greek and French, by M. Halma.

Almagrerite. Native anhydrous sulphate of zinc, found in Spain, at the Barranco Jaroso Mine in the Sierra Almagrera, in crystals which are isomorphous with sulphate of baryta.

Almacantar (from the Arabic). A term used by the old astronomers to denote a small circle of the sphere parallel to the horizon.

Almanack (probably from the Arabic *al Manack, the diary*). An annual publication containing a calendar of the days and months of the year, the ecclesiastical feasts, the time of the sun's rising and setting, the age of the moon, and the solar and lunar eclipses. To these are frequently added information on various subjects of astronomy, chronology, meteorology, the tides, statistics, lists of post-offices, public institutions, &c., according to the views or fancy of their respective authors. Almanacks correspond in some respects to the *Fasti* of the Romans, and are of very ancient date. The Greeks of Alexandria constructed them about the time of Ptolemy; but the earliest of which Lalande could obtain any notice was that of Solomon ben Isaac Jarchi, published about 1150, and that of the celebrated George Purbach, published from 1450 to the time of his death in 1461. The first printed almanack appeared in 1474, and was drawn up by Regiomontanus, nearly, at least so far as regards the calendar, in the form now used. Till within a few years the numerous almanacks published in England were little creditable to the taste or morals of the country. They had for a long time been monopolised by the Universities and the Stationers' Company, under charter granted by James I., and under their patronage astrology flourished till late in the last century, notwithstanding the attacks of Swift under the assumed name of Isaac Bickerstaff. The Stationers' Company appear to have acted merely on the commercial principle of publishing that which pays; for we find, in 1624, that while they continued their astrological and other predictions in one almanack, they published at the same time another by Allstree, calling the supposed influence of the moon upon the different members of the body 'heathenish,' and dissuading from astrology in doggerel verse. The prognostics connected with St. Swithin's day (July 15) have kept the firmest hold upon the popular mind.

The monopoly enjoyed by the Stationers' Company was at length broken through by Thomas Curran, a bookseller, who had detected some illegality in the exclusive right of the Stationers' Company, and invaded it accordingly. This occurred in 1775. In 1779 Lord North brought in a bill to renew the privilege, but, after an able argument by Erskine, it was thrown out. The *British Almanack*, the first purely unexceptionable work of the kind, was published in 1823 by the Society for the Diffusion of Useful Knowledge; and it induced the Stationers' Company also to issue a good one, the *Englishman's Almanack*. The removal of the heavy stamp duty of fifteenpence per copy, to which they were subjected till 1834 (3 & 4 Will. IV. c. 57), has been attended with all the advantages which usually result from the exercise of free competition. The average number of stamps issued between 1821 and 1830, inclusive, was about 499,000 yearly, producing an average revenue of about £31,000. About 200 new almanacks were published as soon as the

duty was repealed, and of some of these upwards of 250,000 copies were sold.

The *Nautical Almanack* is published by order of the Board of Admiralty, for the use of both astronomers and seamen, and contains a copious list of astronomical phenomena, and of the elements which are used in finding the longitude at sea. This work is also a very complete astronomical ephemeris, showing the instants of time at which the planets and principal stars pass daily the meridian of Greenwich; the sun's right ascension, and the logarithms of his distances; the moon's place at intervals of three hours, &c. This valuable work first appeared in 1767, under the superintendence of Dr. Maskelyne, then astronomer royal, and was continued by him for forty years. From his death till 1834 the almanack continued to decline in value; but in that year certain alterations proposed by the Astronomical Society were adopted by the government, and a new era in its existence was begun. The oldest nautical almanack in Europe is the French, *Connaissance de Temps*, commenced by Picard in 1679.

By the law of England, the only almanack of which cognisance is taken by the Courts of Law is that annexed to the Book of Common Prayer.

Almandine, or Almandine Garnet. The name given to red, transparent varieties of Garnet. It is composed of 36·3 per cent. of silica, 20·5 alumina, and 43·2 protoxide of iron. It occurs in rhombic dodecahedrons, the edges of which are sometimes replaced by six-sided planes, in Ceylon, Pegu, Hindostan, Brazil, and Greenland; also at Elie in Fife-shire, Ala in Piedmont, and in various parts of Bohemia. When transparent and of good colour, this stone is used in jewelry, under the name of Bohemian or Precious Garnet.

Almery. An old term for Ambry, or Aumbry, the designation of a niche formed in a wall by the side of an altar, to contain the instruments belonging thereto, together with the host, holy oil, and chrysmatory. The term is also applied to closets with shelves, buffets, &c., wherein plate, relics, vestments, deeds, &c., were kept: they were usually of large size, and were profusely decorated.

Almond (Gr. *ἀμυγδαλον*, Fr. *amande*). The seed or kernel of the *Amygdalus communis*. Sweet almonds afford, in the 100 parts, 54 of fixed oil, 24 of albuminous matter, 9 gum and sugar, 4 woody fibre, 5 husk, and 4 water and loss. They afford neither volatile oil nor prussic acid when distilled with water. Bitter almonds contain less fixed oil, and a peculiar principle termed *Amygdalin*. When bitter almonds are cold pressed, the oil which exudes contains no trace of prussic acid; when hot pressed, its flavour may be perceived: the cake remaining after pressure yields a volatile oil by distillation, the quantity and strength of which in prussic acid are variable. The distilled or volatile oil of bitter almonds is about the specific gravity of water; that which passes

first over is most poisonous. It changes when exposed to air, and forms benzoic acid: in close vessels it may be long kept without deterioration. When used in medicine, great care is requisite on account of its varying strength. The distilled oil of peach leaves and of the cherry laurel also contain prussic acid, and consequently the water distilled from them is poisonous.

Almoner. An officer in a religious house, to whom the distribution of alms was committed. The term is still retained by officers in some of our hospitals.

Alms (A. S. *Almeþge*). Charitable offerings, from the Greek *ἐλεημοσύνη*, *pity*, which came in the early ages of the church to be used in the plural number in the peculiar sense which is represented in our language by the word Alms.

Alnager, or Aulnager. An ancient English sworn officer, appointed to examine into the assize of cloth, fix seals to it, and collect the alnage duty on all cloths sold (26 Edw. 3, stat. 4, c. 1). These duties were abolished in England by 11 & 12 W. 3, c. 20, and in Ireland by 57 Geo. 3, c. 109. (Wharton, *Law Lex.* s. v.)

Aloe (Gr. *ἀλόη*). A small genus of *Liliaceæ* with endogenous stems, and stiff fleshy juicy hard-pointed leaves, which in some species abound in a purgative principle obtained by simple pressure of the bruised leaves. The juice when inspissated becomes the medicinal drug of the shops.

Aloes. The inspissated juice or extract of several species of aloë. This article is largely imported for medical use from Bombay. It is of a brown colour, a peculiar and somewhat aromatic odour, and a nauseous and intensely bitter flavour: it consists of extractive and resin, and is nearly soluble in boiling water, but the solution as it cools deposits flakes of resin. The best aloes were formerly brought from the island of Socotora, in the Indian Sea, and hence all the finer aloes of commerce are frequently termed Socotorine aloes. Another variety of this drug comes from Barbadoes, in large gourd-shells containing upwards of half a hundredweight each; it is deep-coloured, opaque, and has a nauseous and peculiar odour, especially when breathed upon. Aloes is a warm stimulating purgative, operating as such in the dose of two to five grains. It stimulates the large intestines, and should be administered with caution in habits where there is tendency to piles, and in cases in which uterine stimulants are improper. The aqueous extract of the Barbadoes aloes is an excellent preparation, and operates mildly in grain doses.

Aloetic Acid. A resin resulting from the action of nitric acid on extract of aloes.

Aloexylon (Gr. *ἀλόη*, the aloë, and *ξύλον*, wood). The aloes wood of commerce is reputedly the produce of *A. Agallochum*, the only representative of this genus of pea-flowered plants, a tree found on the high mountains of Cochin China. This wood, also called Lign-aloes and Eagle-wood, yields a

perfume which is highly esteemed by Orientals.

Aloin. The yellow neutral crystalline active principle of aloes.

Alopecia (Gr. *ἀλωπεκία*, a shedding of the hair). A morbid falling off of the hair.

Alopecurus (Gr. *ἀλώπηξ*, a fox, and *οὐρά*, a tail). A genus of grasses, called by the farmer Foxtail Grass; the flowers being arranged in compact tail-like stalks. It is very like *Ptilonotus* or cats-tail grass, from which it differs in its glumes being acute, not truncate, and its lower pales awned. *A. pratensis* forms a part of all the richest pastures in this country.

Aloša (Lat.). The name of a genus of Clupeoid fishes, including the alose, or shad; separated from the herring and pilchard, with which it was classed by Linnæus. The shad ascends large rivers to the fresh water, where it spawns. The white-bait used to be regarded as the young of the shad, but is now ascertained to be a distinct species of the present genus.

Alphabet (from the Gr. *ἄλφα*, *βῆτα*, the two first letters of the Greek alphabet). The letters of a written language disposed in their regular order. An alphabetical language is one possessing an alphabet.

1. The first and most obvious mode by which thought can be expressed and conveyed to the eye, is by the representation of actual objects. Hence the species of writing which the learned have termed *ideographic*, i. e. in which knowledge is conveyed, first, by representations of the objects of thought; secondly, by symbols. The origin of designing is coeval with that of mankind; and men early availed themselves of this art to make their thoughts visible. To make it understood, for example, that one man had killed another, they drew the figure of a dead man stretched on the ground, and of another standing by him upright, with some deadly weapon in his hand. To let it be known that some one had arrived by sea, they drew the figure of a man disembarking from a ship; and so on. This kind of writing, if we may so employ the word, was very early used in Egypt, and probably, also, in most of the ancient nations. In Greek, the word *γραφειν* signifies indifferently either to write or to paint. In Mexico, when the Spaniards landed, the inhabitants of the sea-coast conveyed intelligence of the event to Montezuma by sending him a large cloth, on which they carefully painted what they had seen. It is unnecessary to insist on the difficulty and inconvenience of this method of writing; and to lessen these, recourse would naturally be had to the *symbolic* or *emblematic* variety of ideographic writing. In this method abbreviations or characteristic parts were introduced instead of the entire object. Thus, the ancient Egyptians are said to have represented a siege by a scaling ladder; a battle, by two hands holding a buckler and a bow, &c. Abstract ideas were, also, represented by symbols, or sensible objects, supposed to have a certain analogy to them: as, ingratitude by a

viper, providence by an eye, the head of a hawk, &c. 2. From ideographic was derived syllabic writing. It must have been early remarked that the sounds formed by the voice in speaking are articulate and well-defined: and the idea occurred of endeavouring to represent such sounds by appropriate signs. Thus the word *republic*, in the writing of which we use eight letters, would be written with three syllabic characters. The president De Goguet suspects that originally all the Asiatic nations, known to the ancients under the names of Syrians and Assyrians, used the syllabic mode of writing. We may, he thinks, discern the vestiges of this in an ancient tradition which ascribes the invention of writing to the Syrians; but acknowledges that the Phœnicians improved, made it more simple, and brought the characters to perfection. But this mode of writing, though a great improvement on what is purely ideographic, is still very imperfect and cumbersome. The vast number of characters required in it overburdens the memory, and occasions the greatest confusion. The existing language of the Chinese, which is partly ideographic and partly syllabic, is an example of this. In it there are a certain number of *elementary signs* or *keys* (two hundred and fourteen), which are strictly hieroglyphic or symbolical; that is, they are abridged representations of visible objects. From these 214 elements, all the characters of the language (80,000, it is said) are formed by varying and combining their figures; every compound character representing one or more syllables having a distinct meaning. 3. The defects incident to ideographic and syllabic writing being thus obvious, ingenious individuals would early endeavour to find out some more simple and precise method of communicating their ideas. And at length the method of Alphabetic writing, the greatest of all the inventions made by man, and which has been the most powerful instrument of his civilisation, would be introduced and perfected. In this method syllables are decomposed into their elements; and the few simple sounds emitted by the voice being represented each by its appropriate mark or letter, syllables and words are formed by their combination; the latter serving not only to describe external objects, but to depict the workings of the mind, and every shade and variety of thought. Before entering into the much disputed question respecting the origin of this mode of writing, it is necessary to indicate the light thrown upon the subject by the discoveries of Dr. Young and of M. Champollion, as to the phonetic writing of the Egyptians. We have already seen that the hieroglyphical characters of that people denoted, in the first place, *objects* either of sense or thought; i. e. they were ideographic. But, according to the new theory, they came in the course of time to denote sounds; and those not syllabic merely, but alphabetical. For example, the Egyptian word *Ahom* signified an eagle; the figure of an eagle, therefore, stood, it is said, for the letter A, with which that word begins.

B was represented by a censer (Berbe). R sometimes by a mouth (Ro), sometimes by a tear (Rimé). According to the views of these discoverers and their followers, a great proportion of the inscriptions on Egyptian monuments and papyri are partly ideographic, partly alphabetical; i. e. some characters represent objects or ideas; and these are intermingled with others which merely stand for letters. Dr. Young, who first conceived the notion of the phonetic alphabet, imagined that it was only employed when foreign words or names (as those of Greek kings) were introduced. M. Champollion carried the discovery further, and applied it to the deciphering of words and names in the language of the country. The name of the ancient king Sabaco, among others, being found by this mode of interpretation, would appear to show that the phonetic writing was used as early as 700 years B.C. (See Dr. Young's writings, especially the article 'Egypt' in the Appendix to the *Encyclopædia Britannica*; those of Champollion; M. Klaproth's *Examen Critique des Travaux de Champollion*; *Quarterly Review*, vol. liii. p. 110; Salt's *Essay on the Phonetic System of Hieroglyphics*, 8vo. London, 1825, &c.)

The space at our command will not allow us to enter into any detailed examination of the methods which have been applied in the interpretation of Egyptian and Assyrian inscriptions; and it would probably be rash to pronounce any definite judgement on a question in which enthusiasm on the one side is balanced by a scepticism perhaps too rigorous on the other. If the system of Champollion and his followers be right, it would be hard to place too great a value on the results which may be derived from Egyptian hieroglyphic inscriptions; but it must be remembered that in a great degree the interpretation of the Egyptian hieratic and the Assyrian cuneiform characters must stand or fall together, inasmuch as the method of Sir H. Rawlinson, Dr. Hincks, and others, is based on that of the interpreters of hieroglyphics. At the present time, the case appears to stand thus. A large number of hieroglyphic inscriptions and papyri have been either wholly or in part deciphered; and translators, unknown to each other, have given substantially the same interpretations of the same text. This agreement is especially manifest in the versions which Mr. Goodwin and M. Chabas have recently given of some very ancient papyri, lithographed in the great Prussian work, *Denkmäler Aegyptens*. One of these papyri relates the adventures of a certain Sancha, or Sineh, who rose to power under king Amenemha of the twelfth dynasty. The narrative is almost entirely personal, and throws little light on the previous history of the country. On the other hand, the scepticism avowed in the *Encyclopædia Britannica* (8th edition, art. 'Alphabet') has more recently been taken up by the late Sir G. C. Lewis, who urges the following arguments as reasons for doubting the accuracy of the methods hitherto employed in such interpretations. Apart from the inscrip-

ALPHABET

tions of the country, the history of ancient Egypt has come down to us in the pages of four writers, who all profess to have derived their knowledge from the same source, but whose accounts are utterly irreconcilable except as regards the period succeeding to the dodecarchy, a time which closely approaches to the era of contemporary history. If we confine ourselves simply to these accounts, the principles of criticism would require us to reject them all. Here, however, comes in the alleged discovery of Champollion, with the results attained by later Egyptologists. But this discovery relates confessedly to a dead language, for the modern Coptic first made its appearance in the third century of our era. The power of deciphering the old inscriptions might also determine the affinity of the old Egyptian to the Coptic; but it was useless to apply the analogy of cipher-writing, because a cipher 'is a contrivance for disguising the alphabetical writing of a known language by a conventional change of characters' (Sir G. C. Lewis, *On the Astronomy of the Ancients*, p. 379.) The Kosetta stone appeared at this juncture to supply a hieratic record with its translation affixed; and thus the proper names occurring in the Latin version were, it was thought, identified with certain cartouches in the hieroglyphic inscription. The occurrence of the name Cleopatra on an obelisk at Philæ supplied further the signs for *l*, *o*, *p*, *a*, *t*, and it was discovered that in the hieroglyphic, hieratic, and enchorial writing alike, symbolical and alphabetical characters were intermingled, and that there were *homophone* signs, or different figures representing one and the same sound. This latter hypothesis was rendered necessary by the fact that the language had only fifteen sounds, while the signs discovered amounted to two hundred. Baron Bunsen made the further discovery that by far the greater part of the characters in Champollion's alphabet were not purely phonetic, i. e. not capable of universal application. The existence of the rest Bunsen explained by the necessity 'of employing sometimes a horizontal, sometimes a perpendicular sign, sometimes a loop, sometimes a broad figure, in order to give an artistic shape and finish to each group of words,' (*Egypt's Place in Universal History*, vol. i. p. 333.) In deciphering these hieroglyphics, Egyptologists seem inclined to reject the aid furnished by the analogy of Coptic; but a further difficulty is presented in the meanings attached to the five or six hundred words that make up the Egyptian lexicon, and thus the discovery of more words seems likely only to increase the perplexity. Different signs may stand for the same sound, and the same sound may signify an indefinite number of objects. Sir G. C. Lewis further urges that, although there are one hundred and sixty-four determinatives, yet inasmuch as a 'club' is determinative of 'names of foreigners,' 'to create,' 'wicked,' and 'an eye,' the limitation would not greatly define the reader's pathway; and this difficulty is heightened when we are told that, for example,

the word *ka* may mean 'a cow,' 'to begin,' 'to go before,' 'a husband,' 'a duck,' 'a substance,' 'O hail,' 'a day,' 'to set up,' 'duration,' 'an elegant kind of boat,' 'field clay,' 'to rejoice,' 'the head,' 'a limb,' 'self,' 'also.' Still further, it is asserted that this writing was not confined to the priests, but was common to all educated classes; and that this system 'of so much intricacy, consisting of ideographic, syllabic, phonetic, and determinative symbols, with a large class of homophones, or alternative signs for the same sounds, should have remained in common use by a whole nation for twenty-two centuries without alteration,' is, in the opinion of Sir G. C. Lewis, altogether incredible. But the Greeks and Romans either did not believe that these inscriptions were historical, or, if they did, made not the least effort to preserve them, while the accounts left to us of the Egyptian system of writing differ altogether from the explanations given by modern Egyptologists. Thus, Clement of Alexandria speaks of three characters, the epistolographic, the hieratic, and hieroglyphic; but as Clement's text does not in all respects suit his theory, Bunsen applies to it a more free interpretation, and remarks that 'Clement might have expressed himself better and more clearly, but it is sufficient to establish any sense for words which can otherwise have no sense at all.' It is obvious that these arguments, and the answers which may be returned to them, cannot be affected by the historical value of the narratives so brought to light. The inscriptions deciphered may be a barren enumeration of dynasties and kings; they may be the mere expression of royal presumption and popular flattery; and they may also be utterly destitute of a chronology. But the interpretation of the enigmatical characters in which they are recorded, and the grammatical system which has grown up from the discovery of the hieroglyphic alphabet, must stand or fall on its own merits. (*Encyclopædia Britannica*, arts. 'Alphabet,' 'Hieroglyphics,' *Edinburgh Review*, July 1862, art. 'Astronomy of the Ancients'.)

The belief was all but universal among the Greeks and Romans, that the Phœnicians were the inventors of letters, and that the knowledge of it was brought by Cadmus, from Phœnicia, into Greece, about 1600 years B.C. From the Phœnician, therefore, or the Hebrew with which it is closely allied, are incontestably derived:—1. The Oriental alphabets used in Asia west of the Indus, written, like Hebrew, from right to left; the principal being the Syriac, Arabic, and Persian. 2. The Pelasgic, or original Greek alphabet, originally written, like the Phœnician and other eastern languages, from right to left. It was afterwards written consecutively from right to left, and left to right, in the manner that land is ploughed. This procured for it the name of *βουστρόφονος*, or furrowed writing. This species of writing maintained its ground for a lengthened period. The laws of Solon, promulgated about 594 years B.C., were written in it; and it was used

till the fifth century B.C. But writing from left to right was introduced for a considerable period before the alternate or furrowed method was abandoned. Inscriptions dated 742 years B.C. have been found written from left to right, or in the way now practised (Goguet, *Origin of Laws*, Eng. trans. ii. p. 32, &c.) From the Pelagic alphabet were derived the Etruscan and Oscan. From the Ionic, a later variety of the Greek, came the Arcadian, the Coptic, and Ethiopic, the Mæso-Gothic and Runic, and, in comparatively modern times, the Armenian, Illyrian, Slavonic, Bulgarian, and Russian. With regard to Greek writing, it is to be observed that the most ancient mode was in capitals. The small letters now in use seem to have been introduced gradually; for, in our oldest Greek MSS., even as early as the fifth century, they appear intermixed with capitals. But the latter were principally employed until the seventh or eighth century. 3. The Latin alphabet is also derived from the Ionic Greek. In the earliest inscriptions which we possess, the forms of the letters scarcely differ from those in use at the present day; but great varieties have been in subsequent times introduced: first, in the ordinary method of writing it; as, the Uncial, Semi-Uncial, Lombard, Italic, &c. [CHARACTER.] Secondly, in the number and form of the letters contained in the numerous alphabets derived from it. 4. A fourth class of alphabetical languages consists of the Sanscrit and its derivatives. These are very numerous, and are spoken in the continent and islands of India. The antiquity of the Sanscrit alphabet is undoubtedly great; but those who assign to it a separate origin are probably in error. Indeed, the great regularity of the Devanagaree, or most elegant form of the Sanscrit alphabet, and its copiousness (it contains 100 letters), seem to afford strong presumption that it was compiled by some learned individual, or body (like the Russian and other modern Western alphabets), from other forms of writing then in use, and imported into India from the West. The Sanscrit and its derivative languages are written, like European, from left to right. These four classes comprehend all the alphabetical languages in existence. The following table exhibits the number of letters in some of the principal:—

- Class 1. Hebrew, Samaritan, Syriac, and Chaldean, 22 each. Phœnician (known), 17. Arabic, 28. Persian, 32.
- Class 2. Greek, 24. Armenian, 38. Ethiopic, or Abyssinian, 202. Modern Russian, 41.
- Class 3. (which is only a subdivision of Class 2.) Latin, 22. English, 26. French, 28. Italian, 20. German, 26.
- Class 4. Sanscrit (Devanagaree), 100.

Various learned persons have proposed the adoption of a universal alphabet; and have shown that the elementary sounds are reducible to a smaller number than those employed in our Western alphabets. Harris (*Hermes*, book iii. c. 2) estimates them at twenty; Wachtler (*Naturæ et Scripturæ Concordia*) reduces them

to ten. Bishop Wilkins, in his *Essay towards a real Character and Philosophical Language*, estimates them at thirty-four.

The table given in the preceding page contains specimens of the principal alphabets. For cuneiform inscriptions see CUNEIFORM LETTERS.

Alphonsin. An instrument for extracting balls: so called from the name of its inventor, Alphonso Ferri, a Neapolitan surgeon.

Alphonsine Tables. Astronomical tables, constructed and published in 1252 by Isaac Hazan, a learned Jewish rabbi, under the patronage of Alphonsus X., King of Aragon.

Alpine Plants. Low plants which grow naturally in hilly or mountainous situations, where they are covered with snow during great part of the winter; for which reason, in gardens, they require the protection of frames and glass at that season. In this respect Alpine plants differ from rock plants; which, in gardens, only require to be grown among rocks or stones, without the protection of a frame and glass.

Alpinaceæ. One of the names of the natural order of plants called *Zingiberaceæ*.

Alps. This great and important mountain chain may be regarded as a central and culminating portion of the western division of the elevation-axis of the Old World. The eastern division culminates in the Himalayan chain, and numerous spurs and parallel but shorter chains are formed by the Albanian mountains, extending into Greece, the Apennines, and the high lands of Corsica and Sardinia. The Pyrenees form a western continuation, separated by the valley of the Rhone and the Gulf of Lyons; the Carpathians, an eastern link, separated by the valley of the Danube. The Atlas chain of North Africa, and the Sierra Nevada of the south of Spain, are portions of parallel chains, the former separated by the Mediterranean, and the latter connected by the table-land of Spain.

The Alps thus limited rise from the Gulf of Genoa, and soon attain their greatest elevation in Mont Blanc (15,810 feet). At and near this point they form important knots, in which are Monte Rosa, the Jung Frau, and many other well-known mountains, separated by deep valleys. These mountains are for the most part pinnacles or pyramids of porphyritic rock rising out of fields of ice and snow perpetually renewed and yielding the principal glaciers of the chain. These knots are about sixty miles in extreme length. From them the mountains continue towards the east, through the Grisons and Tyrol, and become gradually lower as they approach the valley of the Danube, terminating with the table-land of Carinthia and the hills of western Hungary on the right bank of the Danube. Besides the central knots and ridges of the Alps, there are many parallel and flanking chains and groups and innumerable secondary branches. The mountain knots already referred to include the group of the Bernese Alps. The Jura mountains flank these Bernese Alps, and the valley and lakes of Switzerland lie between. The eastern exten-

ALRUNÆ

mon of the Alps beyond the Great Glockner splits into two branches, the Noric and Carnic Alps, the latter being the continuation of the main chain. It passes into the Julian Alps, and so is connected with the mountains of the Balkan. The higher part of the Alpine chain is about a hundred miles from north to south; eastward the width increases to two hundred miles, and then diminishes to eighty miles at the Balkan.

There are many practicable passes across the Alps, but all are high. The Stelvio is the highest, and is 9174 feet above the sea. The St. Bernard is the highest that has a regularly inhabited house at the summit. The Simplon is the most frequented of those that pass from North to South. The Mont Cenis connects Italy with France. The St. Gothard and Splügen pass cross the crest of the chain, but the others ascend by some valley, and crossing the water-shed avoid the extreme heights. The Alps properly so called have no table-lands directly connected with them. Several of the principal rivers of Europe take their rise from Alpine valleys. The Rhine, the Rhone, and the Danube are the largest.

Alrunæ (Germ. Alraune, Alraun-bilder). Small images carved out of the roots of trees, exhibiting rude representations of the human figure, generally female. Regarded by the northern nations as the Penates, or household gods, of families, they were laid in boxes, and presented with meat and drink. They are supposed by some to represent female magicians.

Alsegno (Ital. *to the mark*). In Music, a notice to the performer that he must recotomence from that part of the movement to which the sign or mark *§* is prefixed.

Alsiaceæ. A rather extensive group of the order *Caryophyllaceæ* of weedy plants, allied to the much more beautiful *Silenaceæ*, from which they are known by their calyx consisting of distinct sepals. The group derives its name from *Alsiæ*, the common Chickweed.

Al-sirat (Arab. *the path*). In Mohammedan Theology, the name of a bridge extending over the abyss of hell, which must be passed by everyone before entering heaven. It is described as being as narrow as the edge of a sword.

Alstonite. A carbonate of baryta and lime, of a white or grey colour, occurring in veins with Galena, at Brownley Hill, near Alston, in Cumberland; and in small six-sided pyramidal crystals, of a pinkish tinge, at Fallowfield in Northumberland.

Alstonite has the same composition as Barytoalcite, but differs from it by crystallizing in oblique prisms, instead of in right rhombic prisms.

Alt (Lat. *altus*, *high*). In Music, a term applied to the high notes of the scale.

Altaité. A telluride of lead, occurring crystallized in cubes, but generally in tin-white granular aggregates, with a yellow tarnish, at the Savodinsky Mine in the Altai, mixed with telluric silver.

ALTAR

Altar (Lat. *altare*). In Architecture, the name given to a consecrated table, generally raised above the ground, on which sacrifice was offered.

In the countries of classical antiquity, there seems to have existed some doubt as to what constituted the difference between the *altare* and the *ara*, and with respect to the meaning of the altar itself. Thus it is supposed that there were three kinds of altars—one for sacrifice externally; one for incense and libations at the foot of the image of the deity; and the third for offerings, which was portable. It is held by some critics that the *altare* was devoted to the *dii majores*, or *coelestes*; the *ara*, or *craticula*, to the *dii terrestres*; and the *focus*, *scrobiculus*, or trench, to the *dii infernales*: otherwise *altare* is regarded as the altar for sacrifice, and *ara* as that for prayer. The distinction drawn by Servius and Pollux between the *altare* and the *ara* must not be overlooked, though it would appear that the distinction between the two was a mere arbitrary one, and that the words were used indefinitely by the ancients. The earliest form adopted was that of square polished stones, on which were placed the offerings to the gods. Whilst sacrifices were confined to libations, perfumes, and offerings of that kind, the altars were small, and even portable; but as soon as men thought they were doing an honour to the Deity by an offering of blood, they began also to increase the dimensions of their altars. Different forms were contrived, according to the nature of the sacrifice, and according to the nature of the worship offered; as, for instance, the altar of the Villa Pamphili at Rome, upon which are to be seen the cavity for holding the fire and the grooves for holding the blood. Many of the monuments of this description were erected merely as testimonies of the piety of those who built them, whilst others were constructed to commemorate some great event: they served for adjuration, as well as for an asylum for the unfortunate, and for the evil-doer. Their forms varied from square to oblong, from triangular to circular. Those of metal were tripodial; those of brick or stone were usually square on plan; and occasionally, according to Pausanias, they were composed of wood. They do not seem to have been of any definite height, inasmuch as they are sometimes seen in bassi-relievi, reaching a little above a man's knee, whilst in others they reach about his middle; though it would seem that the circular altar was the higher in proportion to its diameter. Vitruvius says that they should be kept down in height, so as not to interfere with the statues of the gods, and he proceeds to lay down the heights they should bear. Thus, he states that the altars of Jupiter, and the celestial gods, ought to be the loftiest; next, those of Vesta and the terrestrial gods; then the sea gods were to have theirs a little lower; and so forth. On the festivals of the gods to whom the altars were dedicated, they were decorated with such flowers and leaves as were sacred to the par-

ALTERATIVES

ticular divinity; but, in addition to this casual decoration, the ancient altars furnish us with some of the most elegant bassi-relievi and foliage ornaments that are extant. According to Vitruvius, their fronts were turned towards the east, though often little regard seems to have been paid to their position, as they were occasionally deposited under the peristyle of a temple, and not unfrequently in the open air, or in the public place of a town.

The word *Altar* was adopted by the early Christians, together with the corresponding Greek term *θυσιαστήριον*, (but not, unless, perhaps, in a single instance, *βωμίδα*,) to express the table of the Lord (1 Cor. x. 21.). But the word altar is stated to have been used by the fathers in four different senses (v. Suicer, in voc. *θυσιαστήριον*): for, 1. Christ himself, from Hebr. xiii. 10. 2. The church of Christ in general. 3. Individual members of the church. 4. The Lord's table. It is observed that the fathers of the first three centuries universally speak of the altar, and not of the table, although constantly admitting the charge which the heathens made against them of their having no altars, conceiving the term as used by the heathens to imply the offering of a sacrifice upon the altar, and the presence of the statue of the deity to whom the offering is made. From the fourth century the word table is frequently adopted, as by St. Chrysostom, St. Augustin, &c.

In King Edward's Book of Common Prayer the word 'altar' was retained in the communion service, but great objection being taken to it, especially by Bishop Hooper, on account of the ambiguity of its meaning, and of the apparent sanction it might appear to lend to the Romish doctrines of the Eucharist, it was abandoned, and the word 'table' was substituted for it throughout. This did not, however, satisfy the more violent party, and, on the restoration of the reformed worship, on the accession of Elizabeth, the people proceeded to take the first step towards a real and verbal substitution by pulling down the altars in many churches. Thereupon the queen issued an injunction, wherein she declared that 'it is no matter of great moment whether there be altars or tables, so that the sacrament be duly and reverently administered; and directs that where the altars have been pulled down, tables should be erected in their place.'

Alteratives (Lat. *altero*, *I change*). Medicines which cure diseases by slow and imperceptible degrees, without producing sensible evacuations.

Alternate (Lat. *alternatus*). In Botany, parts are said to be alternate with each other when one is placed upon the stem a little higher or a little lower than the other; the word is chiefly applied to leaves, and is used in distinction to opposite, in which parts arise from the same plane on opposite sides of the stem.

Alternate Angles. When two straight lines are intersected by a third, the interior angles on the opposite sides of the intersecting

ALTITUDE

line are said to be alternate. Thus AMN and MND are alternate angles; and so also are BMN and MNC. If the two straight lines AB and CD be parallel, the alternate angles are equal. Sometimes, especially by continental mathematicians, the angles AMN and MND are called alternate *internal* angles, to distinguish them from such angles as AME and FND, which are called alternate *external* angles.

Alternate Generation. In Biology, that modification of generation in which the young do not resemble the parent, but the grand-parent; so that the successive series of individuals seem to represent two species alternately reproduced. The *salpa*, a floating gelatinous molluscous animal, is an example: it may be found as a solitary individual, pregnant with numerous minute *salpæ*, of a more simple structure, which continue after birth to be united together in the form of a long chain floating on the sea. In each individual of this chain there is generally developed an egg, from which is hatched a solitary *salpa*, of the form and organisation of the parent of the chain of aggregate *salpæ*: thus the species is represented by an alternation of simple and aggregate *salpæ*. [PARthenogenesis.]

Alternately or by Alternation. In Proportion, a phrase indicating the transposition of the second and third terms. Thus, Euclid proves (v. 16), that if the first of four like magnitudes be to the second as the third is to the fourth, then *alternately* the first is to the third as the second to the fourth.

Alternation. A term formerly used for what is now called *permutation*. [PERMUTATION.]

Althea (Gr. *ἀλθαία*, from *ἄλθω*, to make sound). The most important species of this family of *Malvaceæ* are the Hollyhock, *A. rosea*, a well-known garden flower, and the Marsh-mallow, *A. officinalis*, the latter of which is a common plant in marshes near the sea, and is used, especially in France, under the name of Guinauve, to form demulcent drinks.

Althein. A white crystalline matter contained in althea root. It is identical with asparagin.

Althionio Acid. An acid isomeric with sulphovinic acid, and probably a compound of that acid with isethionic acid.

Altica. A name applied by Fabricius to a subdivision of the Linnean *Chrysomelæ*, characterised by the oblong body, bifid lip, and thickened hind legs.

Altimetry (Lat. *altus*, *high*, and Gr. *μετρέω*, *I measure*). The art of measuring heights by means of instruments. It is founded on the principle that the corresponding sides of triangles having equal angles are in exact proportion to one another.

Altitude (Lat. *altitudo*). In Astronomy, denotes the angle of elevation of a celestial object, or the angle of the visual ray with the

ALTO

horizon. The altitude of a star is apparent or true. The apparent altitude is the angle ascertained immediately from observation; the true altitude is found by correcting the apparent altitude for refraction, parallax, &c. Altitude is frequently used in Elementary Geometry instead of height. The altitude of a triangle is measured by a perpendicular let fall from the vertex to the base; and the altitude of a cone by the straight line drawn from the vertex perpendicular to the plane of the base.

Alto (Ital.). In Music, the counter-tenor part of vocal compositions, or that immediately below the treble or highest. It is a word also used to denote the tenor violin.

Alto Rilievo. [RILIEVO.]

Aludel. A piece of chemical apparatus used in the process of sublimation, and much resembling the ancient alembic.

Alula. In Ornithology, the group of feathers, attached to the joint of the carpus; as in the snipe. These are also called the 'bastard wings' (*ala spuria*).

Alum (Lat. *alumen*). A salt composed of alumina, potash, and sulphuric acid, and in its usual form containing a large quantity of water of crystallisation. Its octohedral crystals consist of

Alumina	. . . 3 atoms	= 54	10.76
Potassa	. . . 1	= 48	9.95
Sulphuric acid	. . . 4	= 160	33.74
Water	. . . 24	= 216	45.55
Crystallised alum	1	478	100.00

Alum dissolves in about five parts of water at 60°. The solution has a sweetish astringent taste, and is a powerful styptic. When crystallized alum is heated, it melts, and, gradually losing water of crystallization, becomes a white spongy mass, called burned alum.

Alum is largely manufactured for the uses of the arts, especially dyeing and calico printing. What is termed *alum ore* is an aluminous slate containing sulphuret of iron; it is calcined, exposed to air, lixiviated, and the solution so obtained mixed with sulphate of potash, and crystallized. The alum-works near Paisley, and at Whitby, in Yorkshire, are the largest in this country.

Milk, curdled by stirring it with a lump of alum, furnishes *alum whey*, which is sometimes taken as a remedy for relaxed bowels. *Alum curd* is made by beating the white of egg with a piece of alum till it coagulates.

Alum is found *native* in translucent octahedral crystals, and also in fibrous masses, or as mealy efflorescences, on aluminous rocks and lava. The lias-shales of Whitby in Yorkshire, and the lower coal-measure shales of Hurlet and Campsie near Glasgow, until within a few years furnished the chief sources from which the alum of commerce was obtained in Britain; but recently it has been largely manufactured at Manchester, and at Goole in Yorkshire, from the carbonaceous shales of the coal measures.

ALUMINA

Alum Shale (*Alum schist*, or *alum slate*). A deposit consisting of clay, in a state tending to split readily, combined with much iron pyrites and also with an irregular proportion of bituminous or carbonaceous matter. In England the principal alum schists are in the upper part of the lias, developed largely at Whitby in Yorkshire. In Scotland they occur in the coal measures. On the Rhine similar deposits are of tertiary age. There is no reason why they should not be found in rocks of any period. The alum of commerce is obtained by a double decomposition, induced by burning the alum schist slowly with moisture until its condition is sufficiently changed, and then adding sulphate of potash or ammonia. Little or no fuel is generally required, as the bituminous composition of the schist causes it to burn when once set on fire without further help. The slow burning sometimes commences spontaneously, owing to the heat generated by the decomposition of the pyrites when moisture gains access to it.

The alum shales of the Yorkshire coast are associated with deposits of *jet*, a peculiar carbonaceous mineral used for ornamental purposes.

Alumina. Aluminous earth; earth of alum; argil. When a solution of ammonia is added in excess to a solution of alum, a white precipitate falls, which, thoroughly washed, dried, and heated, is nearly pure alumina. There are two properties of this earth which render it of great importance in the arts: one is, that it forms a plastic mixture with water, and, though it is not the predominant ingredient in, yet it confers the valuable property of plasticity upon, all natural clays, which enables them to be moulded into the various forms of pottery and earthenware; the other is the remarkable affinity of alumina for colouring and extractive matter and for vegetable fibre, whence its use in the arts of dyeing and calico printing.

In a pure and crystalline form, alumina constitutes the *sapphire*, one of the hardest and most valuable of the gems. In its common state, aluminous earth is a soft white powder, strongly attractive of moisture; hence, aluminous fossils are often recognised by adhering to the tongue, and many of them exhale an earthy smell when breathed upon, as we observe in common slate. Alumina consists of 52.94 aluminium, and 47.06 oxygen; like the other earths, as they are usually called, alumina, therefore, is a metallic oxide.

Alumina has but a feeble attraction for acids, and does not fully neutralise them; and when it has been heated red-hot, or is in an indurated state, as it exists in the sapphire, in corundum, and some other minerals, it is absolutely insoluble.

The aluminous salts are mostly colourless, soluble in water, and of a sweetish astringent taste. Exclusive of alum, the acetate of alumina is the most important of these salts, being used as a base or mordant by the dyers. [DYEING.] It is usually prepared by mixing a solution of

ALUMINITE

190 parts of acetate of lead with one of 478 parts of alum : a white precipitate of sulphate of lead falls, and acetate of alumina remains in solution.

Aluminite. Native subsulphate of alumina. [WABSTERITE.]

Aluminium, or Aluminum. The metallic base of alumina. It is obtained principally, for the purposes of commerce, from the decomposition of the chloride of aluminum by sodium. The metal is remarkable for its specific gravity, being about $\frac{1}{4}$ that of silver, the specific gravity of aluminum being 2.66, that of silver 10.47. The tenacity and elasticity of aluminum are equally remarkable. It is used largely in the preparation of alloys, and for the cheaper descriptions of jewellery. *Aluminum bronze*, which is an alloy of copper and aluminum, has a golden hue.

Alumocalcite. An impure Opal of a milk-white colour inclining to blue, and containing 6 per cent. of lime, and 2 of alumina. It is found at Eibenstock in Saxony, in veins of ironstone.

Alums. Crystalline compounds similar in crystalline shape and in constitution to common alum, which is a double sulphate of alumina and potash. An alum may contain soda or ammonia in the place of potash, and oxide of iron, of chromium, or of manganese in the place of alumina. All the alums crystallize in octohedra.

Alumstone. A native subsulphate of alumina and potash, from which much of the alum of commerce is made, after frequent roasting and lixiviation in water. It occurs massive and crystallized in modifications of an obtuse rhombohedron; the colour is generally greyish-white, sometimes reddish. The crystals, which line cavities in the massive alumstone, are minute, shining, translucent and white, sometimes brownish externally. The massive kind frequently contains a large amount of silica as an impurity, sometimes to the extent of 60 per cent. Alumstone is principally found in volcanic districts, at Tolfa near Civita Vecchia, in the Papal States, at Musay and Bereghzasz in Hungary, Pic de Sancy in France, &c. Some of the Hungarian varieties are so hard and compact as to be used for millstones.

Alumite. A mineralogical synonym for Alumstone.

Alunogene. A hydrous sulphate of alumina resulting from volcanic action and the decomposition of pyrites in shales. It is found in various parts of North and South America, and at Adelaide in New South Wales.

Alurnus. A genus of coleopterous insects, characterised by having short filiform antennæ, palpi four to six, very short; maxillæ horny and short.

Alveolar (Lat. *alveolus*, diminutive of *alveus*, a cavity). Belonging to the alveoli, or sockets of the teeth.

Alveolate. In Botany, when the surface is covered with numerous deep hollows, as in the receptacle of some *Compositæ*.

AMARANTHACEÆ

Alveolites. A genus of fossil zoophytes, allied to the corallines; one species of which (*Alv. suborbicularis*) occurs in the Portland stone.

Alvine (Lat. *alvus*, the belly). A term generally used as relating to the intestinal excretions.

Alvite. A mineral composed chiefly of silica, lithia, thorina (?), alumina, glucina, peroxide of iron, and water. It is found at Helle and Narestö in Norway, in crystals like those of Zircon and of a reddish-brown colour which becomes greyish-brown by alteration.

Alyssum (Gr. *ἄλυσσον*). A genus of Cruciferous herbs, bearing the common name of Madwort. One species, *A. saxatile*, is popularly known as gold-dust, from the bright yellow colour of its blossoms.

Amadou. German tinder, made of a fungus (*Boletus igniarius*) found chiefly in old oaks and ash trees. It is boiled in water, dried, beaten, soaked in a solution of nitre, and again dried for use.

Amain. A sea term, signifying to yield, to let go. Thus, to strike amain is to lower or let fall the topsails, in token of surrender. To wave amain is to make a signal to a vessel to strike its topsails. Amain is also a term used in letting down a thing into the hold or elsewhere, or in lowering a yard, or the like, to denote that the sailors are to let go that part of the rope which they held before, and let down the thing easily and by degrees.

Amalfian Code. A collection of marine laws compiled by the Amalfians about the end of the eleventh century. It was for a long time the authority in countries washed by the Mediterranean.

Amalgam. A combination of mercury with other metals. Metallists apply the term to soft alloys generally.

Amalic Acid. A crystalline body resulting from the action of chlorine on caffeine. It is identical with dimethyl-alloxantin.

Amalthæa (Gr. *ἀμάλθεια*). In Mythology, the name of a nymph, or, according to others, of a goat, which is said to have suckled Zeus (or Jupiter) in Crete. The *cornu Amalthææ* was the magic *cornucopia*, or horn of plenty.

Amandin. The name given to the vegetable casein of sweet and bitter almonds.

Amanita (Gr. *ἀμανίται*). A group of white-spored Agarics, one species of which, *A. muscaria*, the fly-mushroom, ranks amongst the most poisonous of the fungi of this country. It renders water in which it is boiled so poisonous that animals are killed by it, while the boiled fungus itself is nearly harmless. The liquid procured by it is used as a *fly-poison*, whence the name of the mushroom is derived.

Amanzite. A variety of compact Felspar, from Adelfors in Sweden. It is of a clear grey colour passing into greyish-white.

Amaranthaceæ. The order of Monochlamydeous plants which comprehends the *Amaranthus*, and other similar dry-flowered

AMARANTHUS

genera. Some of the species are cultivated as objects of ornament, as Cockscombs (*Celosia coccinea*), Globes (*Gomphrena globosa*), various species of *Amaranthus*, *Trichinium*, &c.; the principal part consists of tropical species. The order participates in the harmless qualities of *Chenopodiaceae*, from which it is not very different.

Amaranthus (Gr. ἀμάρυτος, from ἀ, neg., and μαρῖνα, *I with r*). The name of certain herbaceous, mostly annual plants, with richly coloured flowers, whose parts are of a thin dry texture, so that they are a long while before they wither. They are types of the natural order *Amaranthaceae*. *Amaranthus melancholicus*, *hypochondriacus*, *caudatus*, &c., are the annuals known in gardens by the names of Love lies bleeding, Prince's feather, &c. The name, in composition with other words, is used to designate plants not belonging to the same genus, but to the same natural order. Globe Amaranth is *Gomphrena globosa*.

Amarine (Lat. amarus, *bitter*). An acicularly crystalline basic substance produced by the action of ammonia on oil of bitter almonds.

Amaryllidaceae (Amaryllis, one of its genera). A natural order of beautiful Endogens, with inferior fruit, six stamens, and six nearly equal segments of the flower. The greater part consists of bulbous species inhabiting the Cape of Good Hope and the tropical parts of both hemispheres. Snowdrops are the most northern form. A few, such as *Agave* and *Doryanthes*, are trees in stature, although only herbaceous plants in duration.

Amarythrin. A product of the oxidation of orsellin ether.

Amasatine (*Isamidi*). One of the products of the action of ammonia on i-atin.

Amaurosis (Gr. from ἀμαρόψ, *dark*). A loss of sight dependent upon defective action of the nerve of vision, and independent of visible injury. It is also called gutta serena, the 'drop serena' of Milton.

Amazon-stone. A beautiful bluish-green kind of Eclspar, found in America, in rolled masses near the river Amazon; also in Siberia, near Lake Baikal, and of a verdigris-green colour on the shores of Lake Ilmen. It is made into ornamental articles.

Amazons (usually derived from Gr. ἀ, *with-out*, and μάχος, *the breast*, but probably to be compared with ἀνδροσύς). A tribe or community of women, who are said to have lived on the plain of Themiskyra, on the banks of the Thermodon, and from that place to have made many expeditions into other countries. Their queen Penthesilea aided in the defence of Troy; another queen, Antiope, was killed and defeated by Theseus. The belief in the legends produced the tradition that, on the advance of Alexander the Great into Asia, the Amazonian queen Thalestris hastened to meet him. The American river Amazons was so called by one of the early Spanish navigators, who fancied that he saw armed women on the

AMBER

banks. The wars of the Athenians and Amazons were depicted in the Pæcile, or painted chamber of the Parthenon. For an examination of the legends respecting the Amazons, see Grote's *History of Greece*, vol. i. ch. 11.

Ambarvalia (Lat., from ambire *arva*, *to go round the fields*). In Roman Antiquities, sacrifices, so called from the victims being carried round the fields (Virgil, *Georgics*, i. 345). These rites were performed by an order of priests, twelve in number, called Arvales Fratres, at the end of May, to invoke the blessing of Ceres on the coming harvest. Crowds of country people accompanied the victim, having their temples bound with oakleaves, dancing and singing the praises of the goddess, to whom libations were made of honey and wine.

Ambassador, or **Embassador**. A word of very uncertain derivation, but supposed to be derived from the Italian word ambasciatore, *to solicit*. In Politics, the name of the highest order of foreign ministers. An ambassador is not only the agent of the country which sends him, but also represents personally the dignity of its sovereign. Since the Congress of Vienna, representatives have been usually divided into three classes: ambassadors, envoys, or *chargés des affaires*, the last of these communicating not between the heads, but between the foreign departments of Governments. The only ambassadors now sent by Great Britain are to France and Turkey: our other ministers abroad are termed envoys, or Ministers plenipotentiary. As to the rights and privileges of ambassadors in England, if an ambassador commit any act which is a crime against the law of all countries, he is punishable as a private alien. But an ambassador is not criminally liable for such acts as are only mala prohibita against statute or custom; as, infringements of the laws of the exchequer. By 7 Anne, c. 12, an ambassador or public minister, and his domestic servants, *bonâ fide* registered are privileged from arrest; and his goods cannot be taken in distress. This statute was passed in consequence of the arrest and ill-treatment of Count Matuschef, the Russian ambassador. As to the rights and duties of ambassadors in modern usage, see de Wicquefort, *L'Ambassadeur et ses Fonctions*, 2 tomes, 4to, 1746; and the *Manuel Diplomatique* of Von Martens.

Amber (Fr. ambre; Ital. ambra; Arab. ambarj). The mineralised resin of extinct pine-trees. It is collected in large quantities on the shores of the Baltic Sea, and is also dug up in alluvial deposits of sand and clay, where it is found in rounded masses associated with fossil wood, iron pyrites, and alum shale. It often contains leaves of plants and insects, which are mostly of extinct species. It is hard and brittle, and becomes strongly electro-negative by friction. It is soluble in alcohol, and has a specific gravity of 1.08. It burns with a yellow flame and a fragrant odour, and leaves 12 or 13 per cent. of a black shining charcoal, which, when strongly heated, yields a little volatile

AMBERGRIS

matter resembling camphor. Distilled *per se*, it affords inflammable gases, water holding succinic and acetic acids, and empyreumatic oil in solution (the spirit of amber, of old pharmacy), sublimed succinic acid (salt of amber); and an empyreumatic oil (oil of amber). The acid, when purified, amounts to from 3 to 5 per cent.

The chief use of Amber is for mounn-pieces of pipes, and as an article of ornament, cut into beads for bracelets and necklaces, &c. It is also used for making oil of amber and succinic acid, and forms the basis of some varnishes.

One of the largest known masses of Amber, weighing eighteen pounds, was found near the surface of the ground in Lithuania, about twelve miles from the Baltic: it is in the royal cabinet at Berlin. For the nature and course of the amber trade in the ancient world, see Sir G. C. Lewis's *Astronomy of the Ancients*, p. 458, et seq.

AMBER was also the name of an English measure of four bushels. [DOMESDAY BOOK.]

Ambergris (Fr. ambregis, grey amber). This substance is found in the intestines of the spermaceti whale: it is probably a product of disease; perhaps a kind of gallstone. It is also found upon the coasts of various tropical countries, in masses of various sizes, of a grey, speckled appearance, and interspersed throughout its substance with the beaks of the *Sepia octopoda*, which is the common food of the whale. When genuine, ambergris has a peculiar odour, not easily described or imitated, and which is exceedingly diffusive, especially in solution, so that a very minute quantity of ambergris is perceptible in perfumes, and is thought to exalt their odour. A grain or two when rubbed down with sugar, and added to a hog'shead of claret, is very perceptible in the wine and gives it a flavour, by some considered as an improvement. The best ambergris is softish and somewhat waxy when cut; its specific gravity varies from .780 to .896: it fuses at 140° or 150°, and at a higher temperature gives out a white smoke, which condenses into a crystalline matter. Its chief component (about 80 per cent.) is a peculiar fatty matter (ambrein), which may be obtained by boiling it in alcohol.

Ambidexter (Lat. ambo, both, and dexter, right hand). One who uses both hands alike, the left as well as the right. Numerous theories have been advanced to explain the preference so generally given to the right over the left hand; but, generally, they seem to be more specious than solid.

Ambitus (Lat). The circumference or extreme edge of any thing; the encompassing border of a leaf.

AMBITUS. In Politics, a term used by the ancient Romans to designate the soliciting and canvassing for offices and honours. It was of two kinds, the one, *ambitus popularis*, laudable; as, where a candidate openly avowed his pretensions, publicly stated the grounds on

AMBROSIAN CHANT

which he solicited the suffrages of the electors, and left them to form their opinion upon his claims without privately soliciting their votes. The other, and more common kind of *ambitus*, was either disreputable or unlawful. It consisted in using artful solicitations, cajolery, offers of money and preferment, and all those resources for corrupting the free choice of electors, so well understood and so successfully practised in our own times. To secure the election, a regular system was devised for ensuring secrecy. The bargain was made by *interpretes*, while the money was held by *sequestres*, until it was distributed to the electors by *divisores*. The bribery of electors was forbidden, although to very little purpose, by repeated acts of the Roman legislature. (Smith, *Dictionary of Greek and Roman Antiquities*; Facciolati, *Lexicon*. See also the article CANDIDATE.)

Ambiotis (Gr. ἀμβλωσις, abortion). The generic name, in the system of Illiger, of the Marsupial genus including the wombat.

Amblygon (Gr. ἀμβλός, obtuse, and γωνία, an angle). In Geometry, an obtuse-angled triangle.

Amblygonite. A phosphate of Alumina and Lithia, in combination with double fluoride of aluminum and lithium, occurring massive and in oblique rhombic prisms, which are rough externally, and of various tints of pale green, near Penig in Saxony, in coarse granite; and at Arendal in Norway.

Amblyopia (Gr. ἀμβλωπία, from ἀμβλός, dull, and ὤψ, the eye). Imperfect vision.

Amblypterus (Gr. ἀμβλός, obtuse, and πτερόν, a fin). The name of a fossil genus of Lepidogean fishes, with obtuse and rounded pectoral and ventral fins, and characterised by having small and numerous teeth, set close together like a brush, which shows the habit of these fishes to have been to feed on decayed seaweed and soft animal substances at the bottom of the water.

Ambo (Gr. ἄμβω; Lat. ambo). A raised platform, from which in the primitive church the epistle and gospel were read to the people. It was also used sometimes for preaching, and was most commonly placed on the north side of the entrance into the choir or chancel. As the ambo was ascended by steps, the office performed there was called the Gradual. The ambos were sometimes moveable; two specimens of this kind may still be seen in the church of St. John Lateran at Rome.

Ambreic Acid. An acid formed by the action of nitric acid on ambrein.

Ambrein. A fat-like crystalline substance found in ambergris. It somewhat resembles cholesterolin.

Ambrosia (Gr. immortal). The food of the gods (as nectar was their drink), withheld from mortals as containing the principle of immortality.

Ambrosian Chant. In Music, (so called from St. Ambrose, archbishop of Milan, who composed it for the church there in the fourth

century): a chant distinguished from the Gregorian by less variety in its melody.

Ambrosian Office. In Ecclesiastical History, (so called from St. Ambrose, Bishop of Milan,) the ritual preserved in the diocese of Milan, in many points of minor importance differing from that of Rome.

Ambry or **Aumbry.** In Ecclesiastical Architecture, a place where charters, &c., and sometimes the sacred vessels, were deposited. Also an office in which charitable contributions for the poor were laid up for safety. In the latter sense the word is confused with *almshouse*; in the former it must be traced to the Fr. *armoire*, Lat. *armarium*, a cupboard. (Wedgwood, *Dictionary of English Etymologies*.)

Ambubaise. A Syrian or Arabic term, meaning musical girls from Syria, who obtained their livelihood by performing in public at Rome.—See Hor. *Sat.* lib. i. sat. 2, v. 1, and *Juvenal*, iii. 65.

Ambulacra (Lat. *ambulacrum*, an *alley*). The narrow longitudinal portions of the shell of the sea-urchin (*Echini*), which are perforated with a number of small orifices, giving passage to tentacular suckers, and alternate with the broad tuberculate spine-bearing portions.

Ambulatores (Lat. from *ambulo*, I walk). The name of an order of birds in the system of Illiger, corresponding nearly with the *Passeres* of Linnaeus.

Ambulatory. Formed for walking. In Ornithology, the term is applied to the feet of birds where the toes are placed three before and one behind.

AMBULATORY. In Architecture, a place to walk in, whether wholly or partially covered. The position of an ambulatory may be either external to the building it was intended to ornament, as in the peripteral temple; or internal, cloister. The peculiar arrangement known as the Rows at Chester constitutes a description of ambulatory, of which there are good specimens in the streets of some continental cities, such as Genoa, Bologna, Naples, &c.

AMBULATORY. In Law, a court which moves from place to place, as in England, the King's Bench, when in old times it accompanied the person of the sovereign.

Ambuscade. A military term derived from the Italian *imboscata*, concealed in a wood. It is also applied to any snare laid for an enemy.

Ambustion (Lat. *ambustio*). A medical term for a burn or scald.

Amen (Heb. *אמן*, signifying, *let it be*, or rather, *let it be irreversibly fixed*). It is understood to express belief and assent at the end of a prayer. It is sometimes translated *verily*, as when used at the beginning of a discourse.

Amende Honorable. In French Law, a species of infamous punishment, to which criminals guilty of an offence against public decency or morality were condemned under the ancient system, and are so still in some instances. Such were, sedition, forgery, sacrilege, fraudulent bankruptcy, &c. The *simple* or *dry amende*

honorable consisted merely of an acknowledgment by the criminal of his offence in open court, bare-headed and kneeling. The *amende honorable* in *figuris* was made by an offender, kneeling in his shirt, a torch in the hand, a rope round the neck, and conducted by the executioner. It was, and still is, usually conjoined with some other punishment; sometimes capital, as in the case of parricides, &c.

Amendment. In a general sense, is any change made in any thing for the better. In Parliamentary Proceedings, it is an alteration in the words of any bill or motion, which it is competent for any member to move when the bill or motion has been read. [PARLIAMENT.]

AMENDMENT. In Law, the correction of an error committed in any process, as the amendment of a declaration, plea, &c. The deficiency of means of amendment in pleading at common law led to the statutes of amendments and joinders, beginning with that of 14 E. 3. All amendments are held to be within the discretion of the court, and allowed in furtherance of justice according to the particular circumstances of each case.

Amenorrhœa (Gr. *â*, neg., *μην*, a month, and *ρῆω*, I flow). Morbid irregularity or deficiency of the menstrual discharge.

Amentaceous. Bearing amenta, or catkins; a name formerly applied in Systematic Botany to such plants as have their flowers arranged in amenta; but as very different kinds of structure were combined by this character, the order *Amentacea* of Jussieu is broken up into several others, the chief of which are *Betulaceæ* and *Salicaceæ*; and the term is now little used.

Amenthes. In Mythology, the kingdom of the dead, or Tartarus of the ancient Egyptians.

Amentum (Lat. *amentum*, a *thong*, or *loop*). A kind of inflorescence found in willows and poplars; it differs from a spike in being deciduous.

Amercement (from the French *merci*). The pecuniary punishment of an offender against the king or other lord in his court, when by his offence he is said to stand at the mercy of the king or lord.

America. The general physical geography of this vast and important tract of land will be most conveniently considered under the three divisions, *North*, *Central*, and *South America*. The chief mountain chains, river systems, and lakes will form the subject of separate articles; some of the special phenomena of the surface, such as *silvas*, *llanos*, *pampas*, are also described under their respective heads.

AMERICA, NORTH. According to the most natural division of the continent North America begins north of the Gulf of Mexico in about 30° north latitude, and terminates in the Arctic Ocean. Its greatest length thus considered is nearly 4,000 miles, and its breadth at the widest part is about 3,500 miles. Its shape would be triangular and regular but for the

AMERICA

projecting peninsula of Florida. The eastern coast is deeply indented by bays, gulfs, and inlets. The western coast has the long and narrow peninsula of California, and the projecting Aleutian or Fox Islands, besides Vancouver's Land, but is not otherwise broken.

North America has two principal mountain ranges, the *Rocky Mountains* and the *Alleghanies*. It presents also a remarkable chain of lakes, the largest in the world, and several very important rivers connected with great river systems. Its bays and gulfs are among the most important that exist, and its plains [*Savannahs*] are on a very grand scale. The descriptive and political geography of this vast and important continent are subjects that do not come within the scope of the present work. The climate of North America belongs to another article.

Mountain Systems.—A triple chain of mountains converging towards and terminating in the lofty plateau of Mexico forms the western boundary of North America. Of these the sierras, or lofty ridges, that extend into and form the Californian peninsula, commencing near Vancouver's Island, form the actual coast line. Within this there is a second coast range of some importance, broken by very wide gaps. This range extends quite to the Arctic Sea. Lastly, there is the great and lofty system of the *Rocky Mountains* [which see]. Between the coast range and this latter mountain system are the great gold-bearing districts of Oregon and California, chiefly consisting of gravels brought down from the higher mountains, and deposited in the narrow valleys that are formed between them and the coast range. Many parts of the main chain are volcanic. At about the 40th parallel of north latitude, or between California and Oregon, all the great chains are crossed by a transverse range, and it is not unlikely that the mountains thus formed, which attain in each chain an elevation exceeding 10,000 feet, govern in some respects the distribution of the gold deposits.

The extreme western coast range, broken at Vancouver's Island, is continued further to the north, and culminates in the very lofty mountain called *St. Elias*, which is nearly 18,000 feet high: near it is another mountain 16,000 feet high. At this point, beyond it to the north-west, and for some distance to the south, the country is volcanic, but there are no recent volcanic cones between Oregon and Mexico.

The snowy mountains of the transverse ridges above mentioned, separating the gold fields of Oregon and California, are succeeded to the south by a great sandy plain watered by the Colorado. At the head of the Gulf of California the chain becomes again important, and continues into Mexico.

Between the great triple range on the west coast and the Alleghanies (which in like manner is a triple but very much lower chain, parallel to the east coast of North America) are the great plains or prairies, the vast desert surrounding the Salt Lake of the Mormons, and the

low lands drained by the Mississippi and its tributaries. To the north are the great lakes and the valley of the *St. Lawrence*, and still further to the north the plains towards the Arctic Ocean, broken by *Hudson's Bay*. The eastern chain, which extends at intervals from Texas to Labrador, ranges only from 1500 to 2500 feet above the sea, and at various places admits of the passage of the rivers. [*ALLEGHANIANS.*]

Lakes.—The principal North American lakes are five, communicating by the *St. Lawrence* with the Atlantic. They cover an area of more than 120,000 square miles, which is nearly half the total area covered with fresh water on the globe. Besides these five are several others, also very large, extending to the west and north, and communicating by *Mackenzie River* with the Arctic Ocean.

Of the great lakes, *Superior* is the largest, but *Michigan* the longest, the former being 460 and the latter 480 miles in extreme length. The areas are respectively 42,000 and 32,000 square miles. Both are deep, their mean depth being estimated at 900 and 1000 feet respectively. The volume of water is thus nearly the same. *Lake Superior* is 596, and *Michigan* 578 feet above the Atlantic. *Lake Huron* is the next in point of dimensions, measuring 275 miles by 92, and having an area of 27,500 square miles with a depth of 1000 feet. The others are much smaller and shallower. The whole group of the North American lakes would appear to have reference to the physical geography and geological structure of the northern part of the land of North America, and the present relations of that land with the Arctic Sea. The lakes occupy depressions on a table land of vast extent, gradually but steadily sloping towards the north. Those of the southern or main group are separated by a watershed of comparatively low lands, or by plateaux of moderate elevation, from the great drainage of the Mississippi on the one hand, and from the drainage of the *Mackenzie* on the other.

A very small geological change has produced, and an equally small geological change of another kind would at once put an end to, this condition. The extent of the basin drained by the lakes is estimated at upwards of 300,000 square miles of country.

River Systems.—The chief river systems of North America are, (1) the *Mississippi-Missouri*, draining into the Gulf of Mexico; (2) the *St. Lawrence* and great lakes, draining into the Atlantic; (3) the *Mackenzie*, draining into the Arctic Sea. There are several smaller systems, some opening into the Atlantic, but most of them into *Hudson's Bay*.

The Mississippi drains the great central basin of North America, and collects the waters of the *Missouri*, the *Ohio*, the *Arkansas*, and the *Red River*. The total length of course (including the winding of the principal stream) is estimated at 4000 miles, and the drainage area at 1,250,000 square miles. The *Amazons*

AMERICA

alone rivals this gigantic stream, but the Mississippi course being almost entirely in temperate latitudes, the importance of its stream to man is much the greater. The Mississippi and its tributaries may be said to drain the whole country between the two principal mountain chains of North America south of the transverse plateau, extending to the south-east from between Oregon and California.

A number of important but little known rivers drain the country to the north and west of this same dividing range, and enter Hudson's Bay at various points. The Mackenzie completes the drainage of the north of the continent, and the course of all these streams is broken by numerous large lakes. The St. Lawrence and the system of great lakes may be said to form an outlet for the rest of the water falling on the North American continent. None approach in length of course, or in area of drainage, the proportions of the great Father of Waters (Mississippi). The course of the St. Lawrence is estimated at 2000 miles, including windings, and the drainage area is 400,000 square miles.

Plateaux and Low Plains.—The great central plain of North America is a very remarkable feature in the physical geography of the New World. Reaching from the Gulf of Mexico to the Arctic Ocean, it includes the valleys of all the principal rivers, and occupies an area of more than 4,000,000 square miles.

This great expanse is widest towards the north, and has no elevation interrupting it except a low plateau near the Canadian lakes, forming the watershed between the streams entering the Arctic Ocean and those which proceed to the Gulf of Mexico or the Atlantic. The elevation above the sea is for the most part only about 700 feet, and nowhere exceeds 1600 feet. The land slopes gradually towards the plateau from both extremities of the continent, and for the most part it is wonderfully rich and fertile.

The southern part of the plain, having the advantage of a sub-tropical climate and much rain, is extremely productive when cultivated. It includes the *savannahs* of the Mississippi and some monotonous tracts of sand covered only with pines. To these succeed the *prairies* of the north-west, which are well watered. The plains of Canada and the other countries to the north are also rich, but have a less genial climate.

A wide and rich tract of low plains extends between the Alleghanies and the Atlantic seaboard.

AMERICA, CENTRAL. Under this name we include the table land of Mexico, continued in a narrow belt of land to the south-east, from which rise the volcanic mountains of Guatemala. These mountains, continued in the Isthmus of Panama, connect the northern mountains with the great mountain chain of the Andes. Of this district Mexico affords the largest tract of land. It has a river system and mountain chains, but no lakes of great magnitude. The

northern part of the tract is often regarded as a part of North America.

Table Land.—The great table land of Mexico begins at Tehuantepec, where is a narrow neck or isthmus distinct from that of Panama, and it extends towards the north-west into North America, constantly expanding. At the city of Mexico, the breadth is about 400 miles, and it is there 7600 feet above the sea. It rises very abruptly on all sides, but the top is divided into four broad plains, surrounded by hills a thousand feet high. On one of these stands the city of Mexico.

The greater part of the table land of Central America is broken by crevices or barrancas, many of which lay bare volcanic phenomena, and a line of active volcanoes extends near the city of Mexico from the shores of the gulf to the Pacific.

Another important table land is that of Guatemala. It is volcanic, and occupies the entire space between the Isthmus of Tehuantepec and that of Panama. Nearly forty volcanic mountains appear in this narrow space, at elevations varying from three to thirteen thousand feet above the sea. The loftiest mountain in Mexico (Popocatepetl) is also volcanic, and is nearly 18,000 feet above the sea. It is in a state of almost constant eruption.

Central America connects the Rocky Mountains with the Andes. The whole northern tract may be regarded as a broad-topped mountain chain, about 100 miles wide towards the north-west, but narrowing very greatly, and becoming a mere ridge towards the south-east. The great silver mines of Mexico are in the higher part of the table land, where it passes into the mountain chain. They extend towards the summits of the higher mountains.

River Systems.—The Rio del Norte is the only important river of Central America, and it drains only the northern district. It has a total length of two thousand miles, (including all windings,) and drains a quarter of a million of square miles of country, entering the Gulf of Mexico at about 26° north latitude. A number of small lakes occur on the table land at various elevations, and streams from them enter the Gulf of Mexico and the Pacific.

AMERICA, SOUTH. The greatest length of South America, from Cape Horn or Horn to the Isthmus of Panama, is about 4700 miles, and its extreme width is 3200 miles. Triangular in form, like so many of the principal tracts of land on the earth, its northern half is partly enclosed between the great chain of the Andes running along the west coast, and the less important mountains of Brazil in the north-east, and Venezuela in the north. The rest of the continent consists of vast plains at various elevations, chiefly in terraces. It is drained by some of the largest river systems on the earth.

South America is extremely remarkable for its great mountain chain of the Andes, described in a separate article, for its gigantic rivers, and for its singular plains, some of which, under

AMERICA

the names of PAMPAS, LLANOS, SILVAS, are also noticed separately.

Mountain Systems.—The chain of the Andes commences at the Isthmus of Panama, and ranges close to the coast, at first in a double or triple line, and afterwards in a single chain to the furthest extremity of the continent, and so southwards into the ocean. It is almost everywhere volcanic. Generally close to the shore of the Pacific there is only a narrow strip of land on the slopes available for vegetation, and owing to the clouds being chiefly attracted to the mountains, and the rain conducted into the drainage of the eastern slopes, scarcely any rain falls along the greater part of this coast. (See **ANDES**.) The Organ Mountains in Brazil are parts of a complicated mountain system towards the north-eastern part of the Continent.

Table Lands.—Among the mountains in the northern part of the continent, and between the parallel chains, there are a few very lofty table lands. There are others in those places where the parallel ridges are connected by short transverse mountain chains, forming what are called *knots*. On these lofty elevations, some of them more than twelve thousand feet above the sea, are large and populous cities surrounded by cultivated tracts and numerous villages. These existed as centres of civilisation long before the Spaniards discovered and settled in the country. One of them is four hundred miles in length, with a breadth varying from 30 to 60 miles, and is situated in the Bolivian Andes. It occupies 160,000 square miles. It is a remarkable mining district, and is well peopled. On it is the Lake of Titicaca, about twenty times the area of the Lake of Geneva, the level of its waters being not less than 13,000 feet above the sea. Mountains rise from these enormous elevations, as from the plains of Switzerland, and to nearly as great an elevation above the plains.

The low lands on the east of the Andes are divided by table lands and mountains into three parts, the PAMPAS of Patagonia and Buenos Ayres, the SILVAS of the Amazons, and the LLANOS of the Orinoco. [See these articles.] The eastern mountains beyond these, and the chains to the north, are far less elevated than the Andes, and comprise several chains of no great elevation.

River Systems.—Of all the river systems and rivers of South America, that of the Amazons is the most gigantic, and the most interesting. Taking its rise in Upper Peru at a very great elevation, it proceeds, under the name of Marañon, in a deep north and south valley, till it bursts through the eastern ridge, when it at once takes a new course towards the east, and continues with the same bearing for nearly four thousand miles, till it enters the Atlantic without delta, conveying its tribute unbroken to the ocean. It receives tributaries proportioned to its magnitude and importance. More than twenty noble rivers, all navigable almost to their sources, pour their waters into it: some

AMETHYST

of them are a mile wide at their junction, and have separate courses of more than a thousand miles. Innumerable islands are formed by it during its course, and its depth is generally very great. Its waters discolour the ocean to a distance of more than three hundred miles from the mouth of the river. The Amazons is subject to inundation, the water rising in December, attaining its greatest height in March, and falling till July and August, when it is lowest. The Amazons is considered to drain at least two millions of square miles of country.

The Rio de la Plata, or Plate River, is only less gigantic than the Amazons. For 200 miles from its mouth it is never less than 170 miles broad, and one of its tributaries, the Paraguay, may be ascended by vessels of considerable burden, through 19° of latitude above its junction with the main stream. The principal stream of the Plata rises in Brazil, and runs for 500 miles on the table land towards the south before taking its main course. It then falls over a hundred miles of rapids and cataracts, and continues with an easterly course under the name of the Paraná, receiving three large rivers. Before reaching the Atlantic, it receives the waters of the Uruguay. The whole stream is subject to extreme floods, the ordinary inundations covering many thousand square miles, and the extraordinary desolating whole provinces.

The Orinoco is the third gigantic river of South America. Rising in the Andes like the others, it first runs north, and then, combining with other large streams, turns eastward. A part of its waters joins the Amazons, the two rivers thus interlacing by a natural canal. It drains an area of 300,000 square miles, of which the upper part is impenetrable forest. It is navigable for 1,000 miles above its mouth, and receives many navigable rivers. Like the other rivers proceeding from the Andes and crossing South America, it is subject to floods, which are more regular than those of the Amazons and Orinoco.

There are many other large and important rivers in South America, some entering the Caribbean Sea, but most of them crossing the continent. They are more connected and less separated by mountain chains than the river systems of other countries, and almost alone among the great rivers of the world they exhibit the phenomena of *anastomosis*, or the existence in some part of their course of natural channels connecting their waters. [**RIVER SYSTEMS**.]

Ametabolia (Gr. *ἀ*, without, and *μεταβολή*, change). A sub-class of insects which do not undergo any metamorphosis.

Amethyst. A purple variety of Rock Crystal, the finest kinds of which are found in Brazil, India, Ceylon, Persia, Morocco and Siberia; but it also occurs in Ireland, Auvergne in France, Spain, Saxony, Hungary, Transylvania, the Harz, &c. The name *ἀμέθυστος* (from *ἀ*, neg., and *μέθυσκω*, to inebriate), was given to

it by the ancient Greeks from some influence the stone was supposed to exercise in preventing those who wore it from becoming intoxicated.

Amia. The name of a Linnæan genus of abdominal fishes, founded on a single species (*Amia calva*, Linn.), native of the freshwater streams of Carolina, North America, and which is still its sole representative. It is an example of the Saurid fishes of Agassiz, and is remarkable for the cellular structure of its air-bladder, which, as Cuvier remarks, is similar to the lung of a reptile.

Amiantholide. A variety of Amianthus from Oisans, in Dauphiny, the fibres of which are somewhat elastic.

Amianthus or **Mountain Flax** (Gr. *ἀμιαντος*, *undefiled*). A term applied to the more delicate kinds of Asbestos, in consequence of the simple manner by which, when soiled, it may be restored to its original purity by the action of fire. The cloths in which the ancients wrapped the dead bodies of persons of distinction, before they were burned on the funeral pile, are supposed to have been made of this substance. By this means they were enabled to collect the ashes and unconsumed bones for subsequent inhumation in vases, free from any admixture of extraneous matters. Amianthus is chiefly found in cavities of the older crystalline rocks, in the alps of Dauphiny and Switzerland, in the Pyrenees, Greenland, N. America, &c. It is also met with in the granular limestone and serpentine of Sweden, the Ural, Silesia, and New South Wales.

Amicable Numbers. Two numbers are said to be *amicable* when each is equal to the sum of the aliquot parts of the other. The first or least pair of amicable numbers are 220 and 284; they were found by E. Schooten, with whom the name *amicable* appears to have originated, though Rudolphus and Descartes were previously acquainted with this property of certain numbers. A formula for amicable numbers was, in fact, given by Descartes and afterwards generalised by Euler and others.

Amictus or **Amice** (Lat.). Any upper garment worn by the Romans over the tunic. It is also a square piece of linen worn over the shoulders by Roman Catholic priests.

Amides. Compounds containing a base apparently composed of one atom of nitrogen, and two of hydrogen.

Amidin. The soluble part of starch.

Amido-acids. Organic acids which are formed by the union of one equivalent of the hydrate of a dibasic acid and one equivalent of ammonia, two equivalents of water being expelled.

Amidogen (the generator of *amides*). A compound of one atom of nitrogen and two atoms of hydrogen: this compound has not been isolated, but may be traced in combination with other substances, constituting compounds called *amides*: thus *potassiamide* is a compound of the metal potassium with amidogen; and, in reference to the same view, ammonia

[which see] is an amide of hydrogen. Amidogen is thus represented by the symbol NH_2 , and ammonia as $=NH_3 + H$, or NH_4 .

Amid-ships. A nautical term, denoting the middle of the ship, either with respect to her length or breadth.

Amines. Chemical substances resembling amides and amido-acids in constitution, but containing electro-positive or basic radicals. They are monamines, diamines, or triamines according as they are derived from a single, double, or triple atom of ammonia, and are primary, secondary, or tertiary, according as one-third, two-thirds, or the whole of the hydrogen is replaced by radicals.

Amisatine. A crystalline body derived from indigo.

Ammelide. A white neutral chemical compound derived from ammeline by the action of strong acids.

Ammeline. A white crystalline feebly basic substance, resulting from the action of acids or alkalis upon melam.

Ammiolite (Gr. *ἄμιον*, *vermilion*). An antimonide of mercury mixed with clay and oxide of iron, forming a red powder. It is found at the quicksilver mines in Chili, and at Silbe in Westphalia.

Ammocotes (Gr. *ἄμμος*, *sand*, and *κοίτη*, *a bed*). The name of a genus of Cyclostomous fishes, of which the 'pride' or 'stone grig' (*Amm. branchialis*), is a well-known example. This fish buries itself in the sand or clay of the banks of rivers, has many of the habits of a worm, possesses a skeleton reduced to membranous consistence, and ranks amongst the lowest of organised vertebral animals.

Ammodytes (Gr. *ἄμμοδύτης*, *a sand burrower*). The name of a Linnæan genus of apodal fishes, characterised by a compressed head, narrower than the body; and both elongated. Gill-openings large, with seven branchiostegal rays; dorsal fin extending nearly the whole length of the back; anal fin of considerable length; dorsal and anal fins separated from the caudal fin. The sand eel (*Ammodytes tobianus* Linn.) and the sand-launce (*Ammodytes lancea* Cuv.) are examples of this genus.

Ammon. In Mythology, apparently a Libyan divinity, adopted by the Greeks, and by them identified with their Jupiter.

— stat corniger illic
Jupiter, ut memorant, sed non aut fulmina vibrans,
Aut similis nostro, sed tortile cornibus Ammon.
LUCAN, *Pharsal.* ix. 510.

The name has been derived from *ἄμμος*, *sand*, to which the situation of his temple in an oasis, surrounded by African deserts, might seem to point: but Herodotus (ii. 42) identifies the name with the Egyptian Amoun. Alexander visited the temple, and assumed the title of son of this divinity, in order to impose on Oriental imagination. It possessed a celebrated oracle. [ΚΝΕΡΗ.]

Ammonia. Volatile alkali. This important compound is chiefly produced artificially. It

AMMONIA-ALUM

exists, combined with acids, in some of the saline products of volcanos, and, in very small quantities, is discoverable in sea-water. It is found in putrid urine, and in the salts produced by the decomposition of animal matter; it exists occasionally in very minute quantities in the air, especially in large towns where pit-coal is burned; and the small stellated crystals which are sometimes observed on dirty windows in London, consist of sulphate of ammonia.

Ammonia was originally obtained (in the form of muriate of ammonia) by burning the dung of camels, which was collected for the purpose in Egypt, especially about the temple of Jupiter Ammon (whence the term *sal ammoniac*). It was afterwards procured by the distillation of putrid urine. At present, the demand for ammonia in its various states and combinations is in this country chiefly supplied from two sources—the distillation of pit-coal, and that of refuse animal substances, such as bone, clippings and shavings of horn, hoof, &c.

When coal is distilled [Gas], a large quantity of ammoniacal liquor, as it is called, is formed, to which sulphuric or muriatic acids are added so as to form a sulphate or a muriate of ammonia. When the animal substances just mentioned are distilled, a quantity of impure ammonia passes off with the other products, which is also converted into sulphate or muriate of ammonia.

Pure ammonia is obtained in the form of a gas, by heating a mixture of quicklime and muriate of ammonia. It is very pungent and acid; and so soluble, that one measure of water absorbs nearly 500 of gaseous ammonia: this solution is known under the name of liquid ammonia, and is used in medicine. Ammonia is a compound of nitrogen and hydrogen; it consists of

Nitrogen	1 atom =	14	82.35
Hydrogen	3	3	17.65
	1	17	100.00

It is decomposed when passed through a red-hot tube, and every 100 volumes of ammonia are resolved into 200 volumes of a mixture of 3 volumes of hydrogen and 1 of nitrogen.

Carbonate of ammonia is used in medicine as a stimulant, and frequently employed, under the name of smelling salt, as a restorative in faintness. It is obtained by sublimation from a mixture of muriate of ammonia and carbonate of lime. Muriate of ammonia has been above referred to as the common source of pure ammonia. Sulphate of ammonia is also manufactured for the same purposes.

Ammonia is recognised by its pungent smell, by its transient alkaline effect upon vegetable colours, and by producing white fumes when approached by muriatic acid. Thus, if we burn a piece of quill, and hold a glass rod dipped in muriatic acid near the smoke of it, dense white fumes appear, announcing the presence of ammonia, formed by the action of heat upon the animal matter.

Ammonia-alum. A hydrated sulphate of

AMNESTY

alumina and ammonia, found in thin layers and in octahedrons, in Brown Coal, at Tschermig in Bohemia. An alum in which the potash of common alum is replaced by ammonia is now in common use.

Ammoniacum. A gum resin used in medicine: it is imported in drops and cakes from Africa and the East Indies, and is said to be the produce of the *Dorema ammoniacum*. It is of a pale buff colour, and stands in the materia medica among the mildly stimulating but uncertain expectorants. It is sometimes applied externally in the form of a plaster.

Ammonites. An extinct genus of molluscous animals which inhabited convoluted chambered siphoniferous shells, sometimes called *Cornua ammonis*, and vulgarly snake stones. From their affinity to the nautilus, and the known organisation of the animal of the pearly nautilus, fossil shells of this genus are referred to the Tetrabranchiate order of Cephalopods, and constitute the typical genus of the second family of that order (*Ammonitidae*). They are characterised by their conspicuous whorls, and the marginal-external position of the siphon. They abound in the strata of the secondary formation, varying from the size of a bean to the dimensions of a coach-wheel. Their name is derived from their resemblance to the horns upon the statue of Jupiter Ammon.

Ammonitidae. A family of Cephalopoda, with chambered siphoniferous shells, characterised by the septa being sinuous, with lobated margins. The species of Ammonitidae exceed 500, and their range is coeval with the secondary rocks.

Ammonium. The hypothetical metal supposed to exist in the salts of ammonia. Ammonium is the analogue of potassium and sodium, the known metals contained in the salts of the fixed alkalis. It has never been obtained in the free state, the nearest approach to isolation being a light spongy amalgam formed by double decomposition of chloride of ammonium and an amalgam of sodium.

Ammophila (Gr. *ἄμμος*, sand, and *φίλος*, I love). The name of a genus of Hymenopterous insects, called sand-wasps. The generic characters are, proboscis conic, inflexed, concealing a bifid, retractile, tubular tongue; jaws forcipated, three-toothed at the tip; antennæ filiform in each sex, with about fourteen articulations; eyes oval; wings plane; sting pungent, concealed within the abdomen.

Ammunition. In Military Language, signifies all sorts of warlike stores and provisions, but more especially powder and ball.

Amnesty (Gr. *ἀμνηστία*, oblivion). In Politics, freedom from penalty, granted by a solemn act to those guilty of some crime. Usually, by an act of amnesty is meant one passed to comprehend a number of individuals guilty of offences of a political nature, as rebellion, &c. Among remarkable amnesties in modern European history, may be cited that granted on the restoration of Charles II., from

which were excepted those concerned in the death of Charles I.; that granted on the second restoration of the Bourbons, in January 1816, from which, besides the regicides, several others were excepted by name; and the law of amnesty for political offences in France in 1836. An article of amnesty generally forms part of the treaty which concludes a war. (Phillimore on *International Law*, vol. iii. 559.)

Amnion (Gr.). The membrane which surrounds the fœtus in utero: it includes a thin watery fluid, the liquor amnii.

Amnios. In Botany, a thin semitransparent gelatinous substance in which the embryo of a seed is suspended when it first appears, and on which the embryo appears to feed in its early stages. Sometimes it is wholly absorbed; sometimes a portion of it is solidified in the form of albumen; occasionally, as in the cocoon, a portion is consolidated into albumen, and a portion remains always in a fluid state. The large cell in which the amnios is secreted sometimes becomes thickened and assumes the form of a bag including the embryo, and called Vitellus, as in *Piper*.

Amniotic Acid. An acid supposed to be peculiar to the liquor amnii of the cow, but now known to belong to the liquor of the allantoids.

Amœba (Gr. ἀμοιβή, alternation). The *Amœba diffusus* of Ehrenberg is the lowest organised Acrite of the order *Rhizopoda* with which zoologists are acquainted. It is a mere gelatinous mass of rounded form, capable of emitting processes and lobes from all parts of its body, which are drawn in again at will. It has been suggested that it forms a temporary or embryonic form of higher *Rhizopoda*.

Amomum. [ΑΜΟΜΟΝ.] One of the names of the plants more commonly called *Zingiberaceæ*.

Amomum (hhamâmâ, Arabic; ἄμωμον, of the Greeks). A Zingiberaceous plant, with aromatic seeds, much employed under the name of cardamoms, grains of Paradise, &c. The species occur exclusively in the hot parts of India and Africa.

Amorphous (Gr. ἀμορφος, without form). A term used in Geology in reference to rocks not crystallizing in definite form. Thus we have amorphous limestone or sandstone, in contradistinction to crystalline limestones and quartz rock. A very large proportion of rocks are of this kind, distinct crystallization being a rare exception. Even the crystalline rocks, such as granite, may be regarded as amorphous in this technical sense of the word.

AMORPHOUS. In Mineralogy, amorphous minerals are those which present no definite or definable forms.

Amorphozoa (Gr. ἀ, priv., μορφή, shape, ζῷον, animal). The lowest organised class of Protozoa, or Acrita. It comprehends the orders: 1. Porifera (sponges); 2. Desmidiæ; 3. Diatomacæ; 4. Gregarinidæ. [ACRITA and SPONGES.]

Amortisation or Amortissement (Fr.

amortissement). In Law, an alienation of lands in mortmain to some guild or fraternity which in its corporate capacity can never cease.

Ampellic Acid. One of the white solids produced by the action of nitric acid on coal tar.

Ampelidæ (Gr. ἀμπελος, a vine). In Botany one of the names of the natural order *Vitacæ*.

Ampellin. A liquid resembling creasote, contained in coal tar.

Ampelis. The name of a Linnæan genus of Passerine birds, characterised by a straight convex beak, of which the upper mandible is the longer, and is subincurved, and emarginate on both sides. The Bohemian chatterer, or wax-wing (*Ampelis garrulus* Linn.), is a well known species of this genus; but is referred in the recent systems of Ornithology to a distinct section or subgenus, retaining the name of Bombycilla, originally applied to it by Brisson.

Amphiarthrosis (Gr. ἀμφί, on both sides, ἄρθρον, joint). A kind of articulation in which motion is scarcely allowed to the surfaces of the bones composing it. The metacarpal, metatarsal, and spinal articulations are examples.

Amphibians, Amphibia (Gr. ἀμφίβιος, having the faculty of existing both in water and on land). In modern Zoology, this term is restricted in its application to those animals which possess organs for breathing water, and organs for breathing air, or gills and lungs conjointly. Many cold-blooded animals, from the slowness of their circulation and the great capacity of their lungs in proportion to the vascular surface which alters the chemical state of the contained air, can remain a long time under water without being necessitated to seek the surface for a fresh supply: such are all the vertebrata called Reptilia by modern zoologists, and which Linnæus, from the above mentioned faculty, included under the term Amphibia: yet if these animals were kept submerged longer than the period necessary for renewing the air in their lungs, they would inevitably be drowned; they are, therefore, not strictly amphibious. Not so, however, with that small portion of the order which retain their branchiæ throughout life; these perenni-branchiate reptiles suffer nothing from a prolonged aquatic existence, but, on the contrary, are most affected by a too long continuance on dry land; a desiccation of their external fringed gills, according to experiments on the *Siren lacertina*, occasioning their death. Those warm-blooded mammalia which have their general form and locomotive instruments adapted for aquatic life, as whales, porpoises, walruses, and seals, are, from the rapidity of their circulation and the prodigious extent of the vascular and respiratory membrane of the lungs, still more dependent upon a fresh supply of air for their existence than the pulmonated reptiles, and are consequently further removed from a true amphibious organisation. This is, in fact, enjoyed

AMPHIBIOLITE

by a very small proportion of the animal kingdom. Besides the perennibranchiate reptiles, a few species of mollusca, as the Ampullaria, and some insects and crustaceans, are the only examples.

Amphibiolite (Gr. ἀμφίβιος, and λίθος, a stone). The name given by Linnæus to parts of reptiles, or amphibia, changed to a fossil substance.

Amphibole (Gr. ἀμφίβολος, equivocal). A name applied by Haüy and some other mineralogists to Hornblende, on account of its resemblance to Augite, for which it may be mistaken.

Amphiboli. In Ornithology, the name of a family of scansorial birds, in the system of Illiger, including those in which the external posterior toe is versatile.

Amphibology (Gr. ἀμφίβολος, doubtful, and λόγος, discourse). In Rhetoric, an equivocal phrase or sentence, of which the sense may bear more than one interpretation.

Amphicoelian (Gr. ἀμφίς, on both sides, and κοίλος, concave). The term used when both articular surfaces of the centra of vertebræ are concave, a character found in fishes, as well as in many Batrachia, and in the extinct sea-lizards (*Enaliosauria*) of the secondary period. In inverse proportion to the degree of ossification of the notochord is the depth of the cups filled by the gelatinous intervertebral substance.

Amphictyonic Council (Gr. ἀμφικτύονες, from the hero Amphictyon; but in its origin the word was doubtless ἀμφικτύες, dwellers round about). A council of confederated tribes. There were several in Greece, but the most important was a congress of the deputies of twelve northern Greek tribes, viz. Thessalians, Bœotians, Dorians, Ionians, Perrhæbians, Magnes, Locrians, Cœnians, Achæans of Phthia, Malians, Phocians, and Dolopians, or Delphians. In the Dorians and Ionians were included the Lacedæmonians and Athenians, who each sent one deputy. Each of these tribes had two representatives in the council called the Hieromnemon and Pylagoras. The congress met twice every year; in the spring at Delphi, and at Thermopylæ in the autumn. Its functions were chiefly directed to religious matters, and more especially the protection of the temple of the Delphian Apollo. The principal ancient authorities which we possess respecting the objects and constitution of the amphictyonic council are to be found in the orations of Æschines and Demosthenes; the 16th book of Diodorus Siculus; 9th of Strabo; and 10th of Pausanias. See also Ant. Van Dale's *Dissertationes*, Amst. 1702; Papers by Valois, in the *Mém. de l'Ac. des Inscriptions*, &c., iii. 191, v. 406; St. Croix, *Des Gouvernemens Fédératifs*; Müller, *Hist. of the Dorians*; Grote, *Hist. of Greece*; Freeman, *History of Federal Government*.

Amphicyon (Gr. ἀμφίς, on both sides, and κύων, dog). A genus of plantigrade carnivorous mammalia allied to the Wah (*Ailurus*), found

AMPHITHEATRE

in the miocene deposits at Eppelsheim, near Darmstadt, and at Sausan, in the South of France. Like most of the fossil carnassial and herbivorous animals of the lower tertiary age, it retained the perfect type of diphyodont dentition. [DIPHYODONT.]

Amphigamous. The most imperfect of all plants, having, as was formerly thought, no trace whatever of sexual organs.

Amphilestes (Gr. ἀμφίς, on both sides, and ληστής, thief). A genus of insectivorous mammalia, found with *Amphitherium* in the oolite. It is, however, generically distinct from that genus.

Amphioxus (Gr. ἀμφί, and ὄξυς, sharp). The name of a genus of fishes, so called because the animal is sharp at both ends. It is recognised as a vertebrate animal only by its gelatinous dorsal chord, which supports a medullary spinal chord or nervous axis, and gives attachment to segmental partitions.

Amphipneusts (Gr. ἀμφίς, on both sides, and πνέω, I breathe). Merrem so calls a tribe of reptiles, comprehending those which have both lungs and gills.

Amphipods (Gr. ἀμφίς, on both sides, and πούς, a foot; feet diversely conformed). The third order of Crustaceans in Latreille's arrangement, and the only one in which subcaudal natatory feet co-exist with sessile eyes.

Amphiprostyle (Gr. ἀμφιπρόστυλος). A term applied by writers on architecture to a temple having a detached row of four columns on the front and back elevations. It is assumed that Vitruvius uses the term to mean a temple without any columns on the sides, and with only a posterior and an anterior portico.

Amphisbæna (Gr. ἀμφίβαινα). A genus of serpents or ophidian reptiles in which the tail and head are equally obtuse, and the scales of the head so similar to those on the back as to render it difficult, on a cursory inspection, to distinguish one extremity of the body from the other. Hence these reptiles have been supposed to have the power of creeping backwards or forwards with equal facility.

Amphiscians (Gr. ἀμφίσκιος, from σκία, shadow). A term used by the ancient geographers, to denote the inhabitants of those climates in which the shadows, at noon-day, fall in opposite directions at different times of the year; that is to say, towards the north when the sun at noon is to the south of their zenith, and towards the south when the sun is to the north of their zenith. The term, consequently, applies to the people who live between the tropics.

Amphitheatre (Gr. ἀμφιθέατρον). A large edifice for scenic representations, gladiatorial or other fights, of a circular or an elliptical form, so as to allow the whole of the spectacle to be witnessed by all the spectators. The Colosseum at Rome, the amphitheatres of Verona, Nîmes, Metz, &c., may be cited as examples of this class of buildings. They are usually open to the sky: they have a large, open, and level space in the centre, with seats rising all round,

AMPHITHERIUM

provided with the necessary staircases, passages, exits, and entrances, and with cellars in which the beasts, or the prisoners condemned to be slaughtered for the amusement of the public, were confined. Amphitheatres were never built by the Greeks during the period of their independence, but they seem to have been an essential part of Roman social organisation, for they were erected wherever that nation established itself permanently, and even in England their ruins are to be seen. Consult Maffei, *Amphitheatre*; Cressy, *Encyclopædia of Engineering*; Viollet le Duc, *Dictionnaire d'Architecture*.

Amphitherium (*ἀμφίς*, on both sides, and *σπλον*, beast). A genus of fossil insectivorous mammalia which is found in the oolitic deposits at Stonesfield, in Oxfordshire. The *Amphitherium Prevostii*, which forms the solitary species, has been erroneously supposed to be a marsupial, but the limited extent of the angular inflection of the jaw turns the scale in favour of its affinity to the placental *Insectivora*. It nevertheless offers many points of analogy with the remarkable marsupial genus *Myrmecobius*, which still exists in Australia.

Amphitrite (Gr.). In Greek Mythology, a daughter of Nereus or Oceanus, and a wife of Poseidon, the god of the sea. In Homer Amphitrite is simply a name for the sea: but in the Hymn to Apollo she is a personal being, and present at the birth of the son of Leto. (Hesiod, *Theog.* 243; Apollodorus, i, 2, 7.)

AMPHITRITE. In Zoology, the name of a genus of cephalo-branchiate or tubicular annelides, characterised by golden-coloured short bristles, arranged like a crown, in one or two rows, on the anterior part of the head. One species inhabits the south coast of England, and forms for its habitation a delicate conical tube of grains of sand, agglutinated together by the mucus exuded from the skin: this is the *Amphitrite auricomma*.

Amphitropal (Gr. *ἀμφί*, and *τρέπω*, I turn). In Botany, this is said of an embryo which is curved upon itself in such a manner that both its ends are presented to the same point.

Amphiuma (Gr. *ἀμφί*, and *ὕμν*, a membrane). A genus of true amphibious reptiles, with a persistent branchial orifice on each side of the neck; palatal teeth in two longitudinal rows; a lengthened body, and four rudimental extremities, each divided either into three or two toes, according to the species.

Amphodelite. A reddish variety of Anorthite, occurring massive and crystallized in the form of Felspar at Lojo in Finland, and at Tunaberg in Sweden.

Amphora (Lat). In Sculpture and ornamental Architecture, a vessel having two handles, used as a measure for liquids by the Greeks and Romans: they are frequently applied as ornaments on sarcophagi, &c.

Amplexicaul (Lat. *amplecto*, I embrace, and *caulis*, a stem). A leaf or bract whose base projects on each side, so as to clasp the stem with its lobes.

AMPLIFICATION

Amplification. In Rhetoric, the lengthening a discourse or a passage by the enumeration of minute circumstances, the employment of epithets, particularity of description, &c., with a view to produce a deeper impression. *Enargization* is properly a species of amplification, in which circumstances and facts are not merely dwelt upon, but represented beyond their true dimensions.

Amplitude. In Astronomy, denotes the angular distance of a celestial body, at the time it rises or sets, from the east or west points of the horizon. The amplitude of a fixed star remains very nearly the same all the year round; that of the sun or moon is constantly changing. At a given latitude, it depends on the declination of the object.

In Mathematics, the term amplitude is frequently used to indicate the angle upon whose value that of some function depends. [ELLIPTIC FUNCTIONS.]

In Mechanics and Physics, the term is applied to oscillating and vibrating bodies, to indicate the distance, angular or otherwise, between the extreme positions assumed by the body. Thus, in the case of the pendulum, the *amplitude of oscillation* is the angle between the extreme positions of the line joining the centres of suspension and oscillation. In the case of liquid waves, the amplitude of oscillation of the several particles on the surface is the difference in level between the crest and trough of the wave.

In Gunnery, amplitude is sometimes used to denote the horizontal distance to which a projectile is expelled from a gun, or what is more frequently termed the range of the gun.

Ampulla (Lat.). In Anatomy, that end of each of the three semicircular canals of the internal organ of hearing which is more dilated than the other.

AMPULLA. In Ecclesiastical History, one of the sacred vessels used at the altar, and at the coronation of monarchs.

Amulet (Low-Lat. *amuletum*). A substance worn about the person, and supposed to have the effect of protecting the wearer against some real or imaginary evils. Those of the Persians and Egyptians are said to have been small cylinders ornamented with figures and hieroglyphics. The Greeks and Romans employed for the same purpose a great variety of gems and small figures of deities, heroes, or animals, the bulls, and various other articles. Some of these were hung around the necks of children, to defend them from the evil eye. In more modern times, scraps of paper or parchment inscribed with verses of the Bible, or with magical characters and jargon, have often been used for the same purposes. The celebrated Arabian talismanic medals are called by the Arabs *Ain*, from the first letter of the inscription always beginning with that character.

Amygdaleæ (Gr. *ἀμύγδαλον*, an almond). A division of Rosaceous plants, comprehending the peach, the plum, the apricot, and similar

AMYGDALIC ACID

objects. The species have all a fleshy or succulent fruit, gum in their bark, and hydrocyanic acid is generally obtainable from their leaves. They occur principally in cold and temperate latitudes.

Amygdalic Acid. An organic acid derived from amygdalin, by assimilation of water and elimination of ammonia, under the influence of alkalis.

Amygdaline. A crystalline principle contained in the bitter almond, which, under the influence of *emulsine* and water, yields hydrocyanic acid, and the volatile oil of bitter almonds. By the action of certain bases amygdaline yields ammonia, and amygdalic acid. The composition of amygdaline is $C_{40}H_{72}O_{12}$.

Amygdaloid. In Geology, rocks are so called which have contained oval hollows now filled up with some crystalline mineral. They are all of the class of igneous rocks and of the nature of lava. The bubbles were originally occupied by gas or steam, and may have been round, but have become elongated by the flow of the molten rock before finally cooling.

Agate, chalcedony, calc-spar, and zeolites, are all found in the cavities of amygdaloid, and the basis may be basalt, greenstone, or any other kind of trap. The ordinary varieties are met with in districts where there is evidence of volcanic action at some distant period, but where at present, and within the historic period, there is nothing to indicate disturbance.

Amygdalus (Gr. *ἀμυγδαλος*). Small trees referred by some botanists to the *Rosaceæ*, and by some to a group separated therefrom and distinguished as the *Drupacæ*. The genus includes the almond, *A. communis*, of which there are two very distinct varieties, the bitter and the sweet; and the peach, *A. persica*. The sweet almond tree, a native of Barbary and Morocco, is remarkable in early spring for its beautiful appearance when loaded with its pale pink flowers, and hence it is largely planted for purposes of ornament. The peach, of which the nectarine is a mere variety with a smooth skin, is considered by DeCandolle as a native of China. It is grown so extensively in America that the produce is sometimes used for feeding pigs.

Amyle or Amylene. This term applies in Chemistry to the hydrocarbon which is the basis of the so-called *Amylic alcohol*, or hydrated oxide of amyle. Amyle contains 10 atoms of carbon and 11 of hydrogen, and is represented, therefore, by the symbol $C_{10}H_{11}$. The volatile oil of potato-spirit (the *Fussil oil* of the Germans) includes this compound.

Amylamine. A light colourless inflammable liquid derived from ammonia by replacement of one of its three atoms of hydrogen by the radical amyle.

Amylic Alcohol. Derived from the fermentation of starch; hence the word *amylic*. Under the name of potato-oil or fusel oil, it is a product of fermentation in distilleries, and is contained in crude spirit. It has a

ANABAPTISTS

powerful suffocating odour and nauseous taste, and its minimum production and subsequent removal are anxious objects of the distiller.

Amylurea. Urea in which hydrogen is replaced by the radical amyle.

Amyridacææ. Balsamic exogenous shrubs or trees, found almost exclusively in the tropics. They have been called *Bursaracææ*. Olibanum and frankincense are produced by species of *Boswellia*; Myrrh, Balm of Mecca, and Bdellium by species of *Balsamodendron*; American Elemi, American Balm of Gilead, and Balsam of Acouchi by species of *Icica*; Resin of Cachilou and resin of Carana by species of *Bursera*; and part of the Gum Elemi of commerce is said to be the produce of *Amyris hexandra*. The genus *Amyris* (myrrha, myrrh) is the type of the order.

Amyrine. A resin contained in the white canary wood of the Philippine Islands.

Ana or AA (contracted from ana). In Medical prescriptions, implies 'of each.'

Anabaptists (from the Greek *ἀναβαπτίζω*, to rebaptize). In Ecclesiastical History, properly, all sects are so called that insist upon the repetition of baptism upon admission into their communion, from a notion of the invalidity of the religious ceremonies of other denominations. There were several such in the early period of the church, as the Cataphrygians and Novatians: but they are to be distinguished from the sects which arose in the fifteenth and the beginning of the sixteenth centuries, under the papal dominion, especially in Germany, and adopted, in their fanaticism, preposterous notions of the qualifications requisite for admission into the visible church. Their idea of primitive society consisted in the rejection of all the customs and decencies of life; in the community of goods and of women; in uncompromising hostility to all modes of artificial life, and to government generally as the foundation of social distinctions. They had of course no indulgence for the ordinances of any church but their own, and required baptism by themselves as the essential preliminary for admission within their pale. Early in the progress of the Reformation, finding their numbers daily increasing under the licentiousness of opinion which the unrestricted abuse of private judgment produced among a rude and uneducated people, they united in a hostile league against all existing institutions, and declared open war against the governments of Lower Germany. After committing the greatest atrocities, and causing an universal panic throughout Europe, their progress was arrested by a complete defeat in Saxony, in which their leader, Muncer, perished. The remnant, however, escaping, established their opinions with more or less moderation of tone in Holland and elsewhere. Some of the party seized soon after upon the town of Munster, overthrew the magistracy, and established society upon their own principles; but eventually were put down with great slaughter. (See as to the Munster Anabaptists, *Mosheim's Ecclesiastical History*, sect.

ANABAS

ii. part ii. c. 3, where reference is made to the best works on the subject.) [BAPTISTS.]

Anabas. A genus of Acanthopterygious fishes, in which the surface of the pharynx is broken into numerous little branched appendages and cells capable of retaining water and of gradually dropping it into the branchial cavity so as to moisten the gills; whereby these fishes have the curious faculty of voluntarily quitting the water, creeping about on land, and even, it is said, of climbing trees. The only known species (*Anabas testudineus*) is the *Perca scandens*, or climbing perch, of the older naturalists. [AMPHIBIA.]

Anabasis (Gr. *a going up*). The title of Xenophon's celebrated description of the expedition of the younger Cyrus against his brother, and of the retreat of the 'Ten thousand' Greeks.

Anableps (Gr. *ἀνάλερα*, *I look up*). A name applied to a genus of Malacopterygian viviparous fishes, characterised by a remarkable projection of the eyes from the sides of the head, and a still more singular structure of the cornea and iris, from which there result two pupils, and the eyes appear to be double on each side, although they have but one crystalline lens, one vitreous humour, and one retina.

Anacanthini (Gr. *ἀνά, up*, *ἀκανθα*, *spine*). An order of fishes, distinguished by an ossified endoskeleton, the exoskeleton in some as cycloid, in others as stenoid scales: fins supported by flexible or jointed rays; ventrals beneath the pectorals, or none; swim-bladder without air-duct. Many of the existing edible fishes belong to this order. It is divided into two suborders, the *Apodes* and the *Thoracici*. To the latter families *Gadidae* (the cods) and *Pleuronectidae* (the flatfishes) belong.

Anacardiaceæ. A natural order of Exogens, founded upon the *Anacardium occidentale*, or Cashew nut. It consists of tropical trees, often abounding in a fluid resin of extreme acidity, but forming a valuable varnish in some cases. Marking nuts, the fruit of *Semecarpus anacardium*, black Burmese varnish obtained from *Melanorrhæa usitatissima*, mastich, Scio turpentine, pistacia nuts, and sumach, are all produced by various species of this order.

Anacardic Acid. An acrid fatty substance, found in the fruit of the *Anacardium occidentale*, or cashew nut.

Anachronism (Gr. *ἀναχρονισμός*). An inversion or disturbance in the order of time: as where, in Shakspeare's *King John*, cannon are introduced, which were not employed until 100 years later.

Anaclastics (Gr. *ἀνάκλαστος*, *reflected*). That part of Optics in which the refraction of light is considered, and which is commonly called Dioptrics. The term anaclastics was used by De Mairan, who investigated the apparent form of the bottom of a vessel when looked at through a body of water.

Anacoluthon (Gr. *ἀνακολούθησις*, *not following*). A Grammatical term, denoting the want of sequence in a sentence, one of whose members belongs to a different grammatical construction

ANAGNOSTES

from the remainder. This figure occurs more frequently in the Greek than in any other language.

Anacolyppa. An Indian plant, the juice of which is used as a preservative against the poisonous effects of the bite of the cobra.

Anacreontic. In Poetry, a species of ode devoted chiefly to the praises of love and

Quid nidi cum multo venerem confundere vino,
Præcepit lyrici Teia musa senis?

The name is derived from Anacreon of Teos, who flourished in the sixth century B.C. The genuineness of the Odes which pass under his name is little believed, but some of them are, at all events, very ancient; and they have been universally admired for their sprightliness. The poems of Anacreon have been rendered familiar to the English reader by the translations of Cowley and Moore. The best editions of the original are those of Fischer and Brunnck.

Anacyclus (Gr. *ἀνακύκλεις*, *to turn round again*). A genus of *Compositæ*, found in the Mediterranean region, and bearing considerable resemblance to the chamomile. *A. Pyrethrum* is the pelitory of Spain, and is cultivated for the sake of its pungent roots, which are used in medicine.

Anadyomene (Gr. *ἀναδυομένη*). An epithet applied to the goddess Aphrodite, in reference to the myth that she rose from the sea. (Hæsioid, *Theog.* 191.)

Anæsthesia (Gr. *ἀναισθησία*, from *ἀ*, *not*, and *αἰσθησις*, *sensation*). In Medicine, diminution or loss of the sense of touch.

Anæsthetics (Gr. *ἀ*, *without*, and *αἰσθησιμαί*, *I feel*). Substances which produce insensibility, apparently by suspending certain of the functions of the nervous system: among these, the vapour of ether and of chloroform are the most manageable, and have lately attracted much notice in reference to the performance of surgical operations under their influence. [ETHER; CHLOROFORM.]

Anaglyphic. Embossed work, in opposition to diaglyphic, or sunk work: the small cameos are good illustrations of the anaglyphic process of effecting a work of art.

Anaglyphy. Sculpture executed in high relief; this word is synonymous with *alto-relievo* when applied in works upon Architecture.

Anaglyptograph (Gr. *ἀνάγλυπτος*, *wrought in low relief*, and *γράφω*, *to engrave*). An instrument invented by Mr. Bate, by which a correct engraving of any embossed object, such as a medal or cameo, can be executed. A point is passed over the medal at an angle of 45°, communicating a motion to a diamond point. As the point passing over the medal is raised or depressed, the diamond point takes a corresponding curve, so that the lines ruled on the plate form certain curves, the effect of which is to give a correct drawing of the medal. (Smeo, *Electro-Metallurgy*.)

Anagnostes (Gr.). A domestic servant employed by wealthy Romans to read to them

ANAGRAM

at their meals and on other occasions. The ancient monks and clergy preserved the same custom, and name.

Anagram (Gr. *ἀναγράμμα*, a transposition of letters). The most proper, and most difficult, species of anagram is that which is formed by the reading of the letters of a word or words backwards: as 'evil,' 'live.'

Live, vile, and evil, have the self-same letters;
He lives but vile, whom evil holds in fetters.

A less perfect anagram is that which is made by transposition of letters *ad libitum*: and an anagram in which the transposition is helped out by the admission of letters not in the original word, or the rejection of some of those which it contains, is termed impure. The manufacture of anagrams, particularly out of proper names, formed a favourite exercise of ingenuity in the 16th and 17th centuries; when a common mode of flattery was by inventing some complimentary transposition of the letters of the name of the person addressed. But none of the anagrams of that period exceed, in felicity, Dr. Burney's on Lord Nelson: 'Horatio Nelson,' 'Honor est a Nilo.'

Anal. In Ichthyology, the fin which is placed between the vent and tail, and expands perpendicularly.

Anal Glands. In Comparative Anatomy, organs for secreting substances, sometimes attractive, but generally repulsive in their properties, and applied to purposes of defence; they present every grade of the glandular structure, from the simple cæcum, or tube, to the conglomerate mass; developed from, and consequently always opening into, the termination of the intestine, near the anus. In insects, the sweet fluid ejected by the aphides, and of which the ants are fond, is, at least in some species, the product of secreting tubules opening near the anus. Odorous substances — sometimes fragrant, sometimes fetid — are in different species of insects respectively emitted from the same part; and the singular defensive acrid vapours discharged explosively by the insects called 'bombardiers' are the products of anal glands. In the mollusks, the most remarkable example of the anal glands is presented by the higher organised cephalopods, where they are represented generally by a single, sometimes by a bilobed or trilobed, cyst, with part of its parietes spongy and glandular, and which secretes the inky fluid which these animals eject to blacken the water around them for the purpose of concealment in time of danger. Among fishes, an anal bag opens by a single narrow duct, as in cephalopods, into the termination of the rectum, in rays and sharks; but it no longer exercises the function of a secerner of colouring matter. In reptiles, the anal bags are either single, double, or triple; and in many species, as in frogs and tortoises, are developed to a great size, and serve for aquatic respiration. In crocodiles they are two in number, and emit into the cloaca a mucous secretion, without any stronger odour. In birds the anal fol-

ANALOGUE

icles have a similar function, but they are aggregated into a single cavity, which is called the 'bursa Fabricii.' In quadrupeds, the anal follicles are generally collected into two sacciform groups, each having an opening near the verge of the anus. The insupportably disgusting odour of the secretion of these glands has rendered some of the viverrine quadrupeds, as the skunk, &c., proverbial; in others, the odour is not stronger than serves to attract the individuals of the same species to one another, and this is the common function of the anal glands in this class of animals.

Anal Valves. A mechanical structure for defending the terminal orifice of the intestines in some of the Cephalopoda, which swim forwards, from the retrograde entrance of foreign or noxious substances. This mechanism is required from the position and direction of the anal opening, which is turned forwards towards the base of the funnel or respiratory channel.

Analclime (Gr. *ἀνακλις*, weak, in reference to its weak electric power when heated or rubbed). A hydrated silicate of soda and alumina, generally occurring in icositetrahedral or twenty-four-sided crystals, which are either colourless and transparent, or white, grey, red, and opaque. It is usually found in the cavities of amygdaloidal rocks, and is common in the trap rocks of Ireland and Scotland. The most perfectly pellucid crystals are met with in the dolerite of the Cyclopean Isles near Catania in Sicily, and in the Tyrol.

Analecta (Gr. *things selected*). In Literature a collection of short pieces, extracts, &c., is termed 'Analecta' (plural).

Analemma (Gr.). In Geometry, the projection of a sphere upon the plane of a meridian, the eye being supposed to be placed at an infinitely distant point of the radius perpendicular to that plane. In this projection, which is also called *orthographic*, all small circles whose planes are parallel to that of projection are represented by concentric circles of the same magnitude as the originals, all circles in planes perpendicular to that of projection are seen as chords or diameters of the meridian circle, and, lastly, all other circles of the sphere are projected into ellipses. [PROJECTION OF THE SPHERE.]

The word analemma also denotes an instrument by means of which some of the common astronomical problems may be solved, though not very exactly. It consists, essentially, of a plane of brass or wood, on which the projection is made, and is provided with a moveable horizon.

Ptolemy wrote a treatise on the analemma, of which there is a Latin translation from an Arabic version, with a commentary by Comandine. Since the invention of trigonometry, however, contrivances of this kind have become almost useless.

Analepsy (Gr. *ἀναλῆψις*, I recover). A species of epileptic attack of sudden and frequent recurrence; but not considered dangerous.

Analogue (Gr. *ἀνάλογος*, according to rule

ANALOGY

or proportion). A body that resembles another. A fossil shell of the same species as a recent one is its analogue. In Comparative Anatomy, an organ which resembles another in its functional relations, as the wing of a bird, is analogous to the wing of the flying lizard (*Draco volans*) and to the wing of an insect, though it be not in its structural relations the corresponding organ of the body.

Analogy (Gr. *ἀναλογία*, the proportion of ratios). In ordinary language, denotes a relation or similarity between different things in certain respects. The conclusions to which we are led concerning one thing, by reasoning from our experience concerning another similar thing, form what is termed analogical knowledge. The word analogy is generally employed to designate an imperfect degree of similarity. Thus, a physician, arguing from the effects which he had seen produced by a drug on one man, to its probable effects on another man, would be said to reason from experience: but reasoning from the effects produced on an inferior animal, to the probable effects on man, would be, more properly, reasoning by analogy. Thus also Bishop Butler, in his celebrated treatise on the *Analogy of Religion Natural and Revealed*, has argued, after Origen, that the same sort of difficulties, which are found in the constitution of nature, must be looked for in the spiritual world, and that the existence of this analogy is a proof that Revealed Religion proceeds from God, the Creator of the material universe.

In Rhetoric, the word analogy is employed in a somewhat stricter sense; it designates, not the specific resemblance between two objects, but a resemblance between the relations in which they stand to other objects. Thus, to term youth 'the dawn of life' is said to be a metaphor by analogy; not because of any actual resemblance between youth and morning, but because the one is to life what the other is to the day. Thus also a hat is analogous to a turban, and both are analogous to a bonnet, having a similar relation to the head of the wearer. In this sense, a porpoise is analogous not only to a fish, but to every other animal which habitually moves and seeks its food in the water. But it often happens that a similarity of relationship to a medium of locomotion, a kind of food, &c., is accompanied with a certain amount of corporeal and organic resemblance; and this constitutes a kind of analogy, though by no means in the strictly logical application of the word.

In Grammar, analogy means a conformity in the principles of organisation of different words or collections of words.

In Geometry, analogy signifies the same thing as proportion, or the equality or similitude of ratios. [PROPORTION; RATIO.]

In Zoology the term analogy is usually restricted to the relation which animals bear to one another in the similarity of a smaller proportion of their organisation; thus the *Ascalaphus italicus*, in the length and knobbed extremities of its antennæ, the colouring of

ANALYSIS

its wings, and its general aspect, exhibits a striking resemblance to a butterfly; but in all the essential parts of its organisation it adheres to the neuropterous type of structure: its relation to the Lepidoptera is therefore said to be one of analogy, while it is connected to the ant-lions by the order of affinity. As it has been found in some instances that two series of animals, arranged according to the greater amount of resemblances, or the relation of affinity, are connected to one another by analogical resemblances at given points of the series, the relation of analogy has been regarded as differing from that of affinity not only in degree, but in kind. If a zoologist, for example, were led, by a too superficial glance at the external resemblances of two animals, to place them in the same series contiguous to one another, and it were discovered that the resemblance was but skin-deep, or limited to a temporary state of being, as a stage of metamorphosis, but contradicted by a dissimilarity of a greater proportion of the internal organisation, then it would be said that he had mistaken a relation of analogy for one of affinity; a phrase which the reader, however, will readily perceive merely expresses the fact that a false judgment had been formed, from not taking into consideration the whole of the points of comparison necessary for determining the mutual relation of animals to each other.

Analysis (Gr. *ἀνάλυσις*, from *ἀνάλω*, I resolve). A Greek word, which signifies the resolution of a thing into its component parts. In Logic, analysis is used in opposition to synthesis, as a method of arriving at adequate definitions. In the synthetical method, we begin by assuming some quality which the subject is known to possess. Finding this to be common to other subjects than the one we wish to define, we add some further property, and so on, until we have adequately distinguished it from all other things. Thus man is an animal, man is a hot-blooded animal, man is a hot-blooded viviparous animal, &c. &c., may be taken as a specimen of a synthetical process. In analysis we should reverse the method: assuming the most distinguishing characteristic, and descending, through successive gradations, to that which is least so. Correspondently with this distinction, an analytical proposition is one in which the subject is implied in the predicate: e.g. 'matter is extended.' A synthetical proposition, on the contrary, is that in which the terms have no necessary connection: e.g. 'John is tall'; 'the world is round.' As applied to mental phenomena, analysis is the referring them to the acts or faculties of the mind which they necessarily imply, either as contemporaneously contributing to their production, or as rendering their production possible by their past operation. [Infra, ANALYSIS in Geometry.]

The distinction frequently made between analytic and synthetic reasoning rests on a somewhat vague use of language. Strictly speaking, all reasoning can be but of one kind.

ANALYSIS

A process of ratiocination admits, however, of being reversed: i.e., we may make certain assumptions, and from them form certain legitimate deductions; and we may then proceed to take the truths thus deduced for granted, and by a counter-process arrive, as inferences, at what, in the former case, were the grounds from which we started. Here it is evident that the distinction lies not in the reasoning, but in the subject-matter concerning which

the proposition advanced to be true, and proceed through the consequences of the hypothesis till we arrive at something known. If this result is true, the proposition is true also, and the direct demonstration is obtained by stating in an inverse order the different parts of the analysis. If the ultimate consequence at which we arrive is false, the proposition was also false. In the case of a problem, we first suppose it to be resolved, and deduce the consequences resulting from that solution till we arrive at something known. If the last consequence involves only something which can be executed, or is comprised among what geometers called *data*, the proposed problem can be solved; and the demonstration, or rather in this case the construction, is obtained, as in the former case, by taking the different parts of the analysis in an inverse order. If the last result is impossible, the thing demanded is also impossible.

ANALYSIS. In Chemistry, this term is applied to the resolution of compound bodies into their elements. It is either *qualitative* or *quantitative*. Qualitative analysis consists in the determination of the component parts merely as respects their nature, and without reference to their relative proportions: it is an imperfect, and often a very easy operation, as compared with quantitative analysis, by which we determine not merely the components of a compound, but their relative proportions: to effect this, much scientific skill and practical dexterity are required, more especially in the identification of new substances. The theory of definite proportionals, or the Atomic Theory, as it is usually called, has materially facilitated many analytical processes, and is especially valuable as furnishing an unerring test or criterion of the general accuracy of the results.

In reference to chemical analysis generally, but more especially as regards organic products, we often employ the terms *proximate* and *ultimate* analysis; the former referring to the immediate combinations which form the subject of experiment; the latter, to their final resolution into elementary principles. Thus, in regard to sulphate of lime, it is resolved by proximate analysis into sulphuric acid and lime, and these are called its proximate elements: but sulphuric acid is itself a compound of oxygen and sulphur; and lime, of oxygen and calcium; oxygen, sulphur, and calcium, therefore, are the results of the ultimate analysis of sulphate of lime; and there are many theoretical points in chemistry dependent upon the views which are taken of the various groupings of these ultimate principles. Wheat flour is a compound of starch and gluten; starch is compounded of oxygen, hydrogen, and carbon; and gluten, of the same elements with the addition of nitrogen; so that the ultimate components of wheat are oxygen, hydrogen, carbon, and nitrogen.

ANALYSIS. In Geometry, a method of conducting geometrical inquiries, invented by the philosophers of the school of Plato, or, according to Theon of Alexandria, by Plato himself, and one of the most ingenious and beautiful contrivances in the Mathematics.

'Analysis,' says Pappus, 'may be distinguished into two kinds: in the first, which may be called contemplative analysis, we propose to discover the truth or falsehood of an affirmed proposition; the other belongs to the solution of problems, or the investigation of unknown truths. In the first we assume the subject of

The names of the ancient writers on the geometrical analysis have been preserved by Pappus in the preface before referred to: they are, Euclid, in his *Data* and *Porismata*; Apollonius, in his treatise *De Sectione Rationis*, and in his *Conic Sections*; Aristæus, *De Locis Solidis*; and Eratosthenes, *De Mediis Proportionalibus*: but of these only the *Data* of Euclid, and some fragments of Apollonius, have come down to our times. The subject has, however, been fully investigated by modern authors, and a complete system of the ancient geometrical analysis may be found in the works of Dr. Simson of Glasgow. [See also Leslie's *Geometrical Analysis*.]

Accordingly analysis is directly opposed to synthesis, which advances step by step through known propositions, from the data to the *quæsitæ* in the case of a problem, or from the hypothesis to the predicate in the case of a theorem. Analysis is the chief, though not the sole instrument of discovery, whilst synthesis adapts itself naturally to instruction. Euclid's *direct* demonstrations, for example, are all *synthetical*; his *indirect* ones, however, retain the analytical character. The methods of conducting analysis and synthesis are the same in kind, the only difference being that, in the hands of the investigator at least, the several steps of the former are experiments suggested by experience, for which no rule can be assigned, whereas in the latter these steps are suggested by previous knowledge gained, in fact, very frequently from a preliminary analysis.

The ancient geometers conducted their analysis by means of ordinary language solely; their successors, on the other hand, very frequently availed themselves thereby of the powerful resources of algebra. As a consequence of this habit the word *analysis*, until a very recent reaction set in, lost entirely its original meaning as a *method* of reasoning opposed to synthesis, and by a strange perversion of terms became synonymous with algebra and the calculus; that is to say, with the *instruments* employed in investigation. The fact that algebra may be, and often is, employed synthe-

tically as well as analytically appears to have been overlooked.

Analysis of Light or Spectrum Analysis. [SPECTRUM ANALYSIS.]

Analytical Geometry. See *Coördinate Geometry*, by which name this application of algebra to geometry is more appropriately designated.

Anamirta. A genus of *Menispermaceæ*, yielding the fruits known as *Cocculus indicus*, imported from India, and said to be extensively used in the adulteration of beer, the intoxicating power of which is increased by means of an acrid irritant poison which they contain. The plant from which these fruits are obtained, *A. cocculus*, is a climbing shrub, and is found in the Indian Islands, Malabar, and Ceylon. The fruits are used externally to destroy vermin.

Anamirtic Acid. The acid of a neutral fat contained in *Cocculus indicus* or the seeds of the *Anamirta*. It is probably stearic acid.

Anamirtin. The neutral fat of *Anamirta* or *Cocculus indicus* seeds. It is probably stearine.

Anamnesia. [REMINISCENCE.]

Anamorphosis (Gr.). In Natural History, expresses the change of form which may be traced throughout the species or higher members of a natural group of animals or plants, either in the actual series, or, as they have succeeded each other in the course of time on this planet which change is usually ascensive, or indicative of a progression towards a higher series of species. It has been conjectured that the succeeding or supplanting species may be actually the species supplanted, but changed, i. e. otherwise and commonly more highly developed, but of this there is no proof; and the term 'anamorphosis' must be understood as expressive of an *ideal* change, in contradistinction to the real or bodily change, called 'metamorphosis,' observed in the development of the individual.

ANAMORPHOSIS. In Botany, when any part assumes an appearance unusual with it. The calyx of the rose assuming the appearance of a fruit, the stipule of a *Prosopis* become spiny, and the stem of a cactus when succulent and lobe-like, are cases of anamorphosis.

ANAMORPHOSIS. A term employed in Perspective, to denote a drawing executed in such a manner that, when viewed in the common way, it presents a confused or distorted image of the thing represented, or an image of something entirely different; but when viewed from a particular point, or as reflected by a curved mirror, or through a polyhedron, it recovers its proportions, and presents a distinct representation of the object.

Ananas or **Ananassa** (Brazilian, *ananas*). The plant that produces the pineapple, *Ananassa sativa* or *Ananas sativus*. It is of South American origin, but has been gradually dispersed through similar climates till it has become apparently wild in parts of Africa and Asia, especially the Malayan Archipelago, where it arrives at a greater degree of excellence than in its native woods.

Anandrous (Gr. *ἀνδρῆς*, from *ἀνδρ*, priv., and *ἀνδρ* (genitive *ἀνδρός*), a male or stamen). When flowers are destitute of stamens, such flowers are more usually called female flowers.

Anapest (Gr. *ἀνὰπῆς*). A foot in Greek and Latin metre, consisting of two short syllables followed by a long syllable.

Anaphora (Gr.). In Rhetoric, a repetition of words or phrases at the commencement of sentences or verses. Thus in Cicero, *Verr.* iv. c. 10, *Verris calumniatores apponebat, Verris adesse jubebat, Verris cognoscebat, Verris judicabat.*

Anapophysis (Gr. *ἀνὰ*, backward; *ἀπόφωσις*, an offshoot). That process of a vertebra which, arising in the dorsal region from above the diapophysis or transverse process, recedes to the side of the centrum, as the vertebra approach the sacrum, and projects more or less backwards. It usually supports and strengthens the joint of the anterior zygapophysis of the succeeding vertebra. It is well developed in the hare and most Rodents.

Anarrhichas. A name conceived by Gesner, and applied by Linnæus to a genus of spiny-finned osseous fishes, characterised by having their mandibular, palatine, and vomerine bones armed with large osseous tubercles, bearing on their summits small enamelled teeth. Anteriorly the jaws support longer and more conical teeth. By means of this powerful dental apparatus the species of this genus which inhabits the northern seas, called the 'wolf-fish,' is enabled to break and bruise the testaceous defensive coverings of shellfish, the soft parts of which form its ordinary food.

Anas (Lat. a duck). The name of a Linnæan genus of Anserine birds, characterised by a large, broad, obtuse bill, furnished at the margin with numerous thin, transverse, projecting plates, and an obtuse papillose or ciliate tongue. The subdivisions of this extensive group of web-footed birds, which were indicated by Linnæus, have since been raised to the rank of genera [ANATIDÆ], and the term *Anas* is now restricted to the species which present a flattened bill, the base of which is always of greater breadth than depth, as wide (or wider) at the extremity as at the beginning; with nostrils placed nearer the upper margin and base of the bill. The legs are shorter and placed farther back than in the geese (*Anser*); they have a shorter neck, and the windpipe is dilated at its lower end into two osseous capsules, of which the left is usually the larger. The ducks, thus characterised, are subdivided into those which have the hind toe provided with a membrane, and those in which it is naked. Both divisions are again broken up into numerous minor groups, which are distinguished by generic terms.

Anasarca (Gr. *ἀνὰ*, through, and *σάρξ*, flesh). A diffusion of water through the cellular membrane of the limbs, as in dropsy.

Anastatica (Gr. *ἀνάστασις*, resurrection). A cruciferous herb called the Rose of Jericho, and by botanists *A. Microchuntina*. It occurs

ANASTATIC PRINTING

in the arid wastes of the extra-European Mediterranean region, and has remarkable hygroscopic properties, in which its interest resides. When growing it is an insignificant little herb, with white flowers; but as it ripens under the influence of drought, it rolls up into a ball, and becomes detached from the soil, and is then carried about by the wind until it meets with moisture, when it unrolls into its natural form. The plant retains this property of expanding when moistened and curling up when dry for many years.

Anastatic Printing (Gr. *ἀναστατικός*, *a setting up*). A process by which all kinds of printing or engravings may be transferred to metal, from which impressions can be taken exactly resembling the original. The printed sheet of paper is moistened with dilute phosphoric acid, and subjected to great pressure upon a zinc plate. The plate is washed with an acid solution of gum, and then inked; the chemical affinities in some instances, and the repulsions in others, causing the lines of the device only to take the ink. The plate is then printed by the ordinary lithographic press.

Anastomosis (Gr.). The communications of vessels with each other.

Anastrophe (Gr. from *ἀναστρέφω*, *to invert*). A name given in Classical Philology to some species of inversion [INVERSION] or departure from the usual order of succession in words. Such phrases as *mecum, vobiscum, &c.*, in which the preposition follows the word governed by it, or in which it is placed between two words governed by it, &c., are instances of anastrophe.

Anatase (Gr. *ἀνάτασις*, *extension*). A mineralogical name for titanic acid or *oxide of titanium*, having reference to the height of the pyramids of the octahedral crystals in which it occurs. These are small, of various shades of brown, passing into indigo-blue, and of a greenish-yellow colour by transmitted light; semi-transparent to opaque; lustre splendid and adamantine. It is found in Cornwall at Looe Mills Hill Quarry near Liskeard; in Devonshire at the Virtuous Lady Mine near Tavistock; in N. Wales at Tremadoc; also in Dauphiny, Spain, the Tyrol, Norway, the Ural, &c. The detached crystals from Brazil resemble diamonds so much in colour, brilliancy and general appearance, as sometimes to be mistaken for them.

Anathema (Gr. *ἀνάθεμα*). Properly, a thing laid by, consecrated, or devoted: hence a person upon whom the ban of the church is laid, is said to be anathematized, or in the Jewish phrase, to be 'anathema.' St. Paul says, 'If we or an angel from heaven preach any other gospel to you than that which we have preached, let him be anathema:' and upon the authority of this and similar passages, the church assumed from the first the power of anathematizing or excommunicating evildoers and heretics.

Anatides. The name of a family of web-footed birds, of the swan, goose, and duck kind, of which the genus *Anas* is the type.

ANATOMY

Anatomy (Gr. *ἀνατομή*, from *ἀνά*, and *τέμνω*, *I cut*). This term literally means *dissection*, but is generally understood to signify a knowledge of the internal structure of the human body, in the acquisition of which dissection is essentially necessary. The anatomy of other animals is usually designated Comparative Anatomy; and that of plants, Vegetable Anatomy (which see).

Although some anatomical knowledge must have been accidentally acquired by the earliest inhabitants of the globe, and although there are several allusions in the early books of the Old Testament to the subject, no dissections of the human body were performed with a view to ascertain the position and structure of its internal organs, or to elucidate their functions, till a much later period.

Homer has, it is true, been complimented, and in some respects justly so, for the precision with which he describes the wounds of his heroes; and the ancient Egyptians are said to have acquired great anatomical skill by their practice in the art of embalming; but these, and similar statements, have no bearing upon the pursuit of anatomy as a science, or in connection with surgery, medicine, and physiology. Thales, Socrates, Xenophon, and Plato, are each quoted by anatomical historians, as having acquired no inconsiderable anatomical knowledge: Plato is even said to have anticipated the celebrated discovery of the circulation of the blood. 'The heart,' he says, 'is the centre of the blood-vessels, the spring of the blood, whence it flows rapidly round: blood is the pabulum of the flesh, for the nutriment of which the body is intersected by canals, like those of gardens, to convey the blood like water from a fountain to the remote parts.'

The first author who is supposed to have written on human anatomy is Hippocrates; and the first recorded dissection was, probably, made by his contemporary Democritus of Abdera. This carries us back to about 400 years before the Christian era, from which period to that of Galen (that is, in the space of 600 years) little progress seems to have been made in the knowledge even of the structure and position of the viscera of the body, much less in their uses and

It would appear from Galen that the most eminent anatomists of antiquity were Erasistratus and Herophilus, who taught anatomy in the celebrated school of Alexandria, and are said to have been the first who were authorised to dissect human bodies: hence, probably, the high rank which the school, founded by the Ptolemies, acquired, and maintained for several hundred years. The works of the above-mentioned anatomical professors have been lost, but they are abundantly quoted by their more immediate successors.

Among the Romans the first anatomist was, probably, Asclepiades, who flourished in the time of Pompey; and soon afterwards Rome became a celebrated seat of medical science. Celsus, Aretæus, and Galen are the ornaments

ANATOMY

of this period; especially the latter, as an anatomist; though it appears probable that his descriptions were often taken from dissections of inferior animals, and applied to the corresponding organs of the human body. It is, however, said, that he anticipated many subsequent discoveries, and that a great part of his writings were for a long time unintelligible, till cleared up and explained by the labours of his successors.

During the dark ages anatomy sustained the fate of other branches of knowledge; and, with few exceptions, little progress was made in it till the revival of learning in Europe. The prejudice, too, against the dissection of the human body was not only maintained, but sanctioned by the highest existing authorities. In the year 1315, a *System of Anatomy* was drawn up by Mundinus, chiefly, it is said, founded upon such parts of Galen's doctrines as had been preserved by the Arabians. This work deserves notice, as having been the anatomical text-book of the schools of Italy for a period of nearly 200 years. Mundinus is, indeed, celebrated by his contemporaries as the restorer of anatomy. Early in the fifteenth century, when learning began to revive in Europe, in consequence chiefly of the introduction of the writings of the Greek authors, numerous treatises on the Sciences made their appearance, amongst which anatomy formed a prominent subject; and among its most successful followers, the name of the celebrated Leonardo da Vinci may be recorded, although he apparently only pursued it in reference to his own art. [See the sketches annexed to *Memorie Storiche di L. da Vinci*, by C. Amoretti, Milano, 1804.] In reference to some of the drawings and their descriptions, preserved in the library of George III., and to which he had access, Dr. Hunter observes, that he saw with astonishment that Leonardo had been a deep student, 'and was at that time the best anatomist in the world.' We must give the fifteenth century the credit of Leonardo's anatomical studies, as he was fifty-five years of age at its close. At the beginning of the sixteenth century Berengarius and Massa wrote upon human anatomy; but such was the authority of Galen, even at that time, that few dared publish any statement or opinions contradicting those of the infallible master. About the middle, however, of the sixteenth century, this spell was broken by the celebrated Vesalius of Brussels, who taught anatomy at Paris and Louvain, and afterwards in Italy. He boldly demonstrated the errors of Galen; described accurately the dissections of the body, corrected and improved anatomical nomenclature, and insisted upon the necessity of diligence and actual observation in dissection, as the only solid foundation of successful medical and surgical practice. He had many opponents, and is said to have been detected in the very mischievous error for which he blames Galen; namely, that of describing the human viscera from dissections made upon quadrupeds.

Among the most remarkable contemporaries or immediate successors of Vesalius, were Fallopius and Eustachius—the former of Padua, the latter of Venice; whose names, as annexed to their discoveries, have been handed down to posterity. Indeed, the schools of Italy seem to have been the only accessible sources of practical anatomy at that period: in France and England an antipathy to dissection prevailed, which was fatal to all anatomical improvement. Cortesius, who wrote at the beginning of the seventeenth century, and who, after having been professor of anatomy at Bologna, filled the chair of medicine at Masmana, complains that he was prevented finishing a treatise on Practical Anatomy, in consequence of having only been able twice to dissect a human body in the course of twenty-four years, 'whereas in the academies of Italy there is that opportunity once every year.'

About this time the name of the renowned Harvey becomes conspicuous in the annals of anatomy: he, like his most eminent contemporaries, studied medicine in Italy. Fabricius ab Aquapendente, who was his master, had just made the highly important discovery of the valves of the veins; and it was this which, probably, more especially directed Harvey's attention to the use of the heart, and the vascular system: for at that time the liver was considered as its great centre, and the veins were supposed to convey the blood from it to the remote parts of the body. Harvey's great discovery of the circulation of the blood was taught by him in his lectures as early as 1616, though not published till 1628, in consequence of his desire to demonstrate the subject in detail, and to collect proofs and illustrations of the correctness of his doctrines. This discovery was not only of vast intrinsic importance, but, as is the case in all similar instances, it led to others; and the route of the blood had no sooner been traced and described, than the manner in which the nutritious part of the food is conveyed into the circulation became an object of research: this was successfully developed by Asellius, an Italian physician, in the year 1627. He was so fortunate as to see the lacteals filled with chyle, and to trace them to their common trunk, the thoracic duct, and thence into the blood-vessels. The lymphatic system was also soon afterwards detected, and first described by T. Bartoline, a Danish anatomist; and this was followed by important details bearing upon the anatomy of the gravid uterus and of the generative system, in which nearly all the celebrated anatomists of Europe had a share; and among them Harvey was conspicuous, though Dr. Hunter attributes, with apparent injustice, his knowledge upon this subject, and even the merit of detecting the use of the arteries, to his master Fabricius. The physiology of generation was more especially followed up by Swammerdam, Malpighi, and Leuwenhoek, who were enabled greatly to extend the bounds of anatomical knowledge by their ingenious use of the microscope.

ANATOMY

Although this country has produced many celebrated anatomists, there is no one to whom we are so deeply indebted as Dr. William Hunter who was born in 1718, at Kilbride, in Lanarkshire, and was contemporary with the celebrated Cullen. Dr. Hunter came to London in 1741, bringing with him an introduction to Dr. Douglas, who was then engaged in a work upon the bones, and was in search of a young man who might assist in his dissections. He found in William Hunter a person so exactly suited to his purpose, that he not only engaged him as an assistant, but received him into his family and made him his son's tutor. As our object here is to give a brief historical Outline of Anatomy, rather than the biography of its successful cultivators, we must pass over many interesting points in Dr. Hunter's early history, till he came before the public as an anatomist in the year 1743, when he communicated to the Royal Society an essay *On the Structure and Diseases of Articulating Cartilages*, and was remarked for his diligence, ingenuity, and skill in the arrangement of anatomical preparations, of which he had accumulated a considerable collection, with a view of pursuing his favourite object, namely, that of publicly teaching anatomy. He commenced this arduous task in 1746, under the auspices of Mr. Sharpe, of Covent Garden, in whose theatre he made his first appearance as a public lecturer. In 1747 he became a member of the Corporation of Surgeons; and in the spring of the following year, having concluded his course of lectures, he accompanied his pupil, Mr. James Douglas, into Holland and France. He returned in time to begin his winter course, during which he not only acquired a high character as an anatomist, but commenced the practice of midwifery, in which he soon attained eminence, founded not merely upon his person and address, both of which were agreeable and well suited to that line of the profession, but upon his anatomical skill; so that in all cases of danger and difficulty it soon became customary to call in his aid. In this respect his celebrity became so extended, that he afterwards acquired great and merited reputation as a general anatomical physician. In 1762 Dr. Hunter entered into a spirited vindication of his claims to certain anatomical discoveries in a work entitled *Medical Commentaries*; and in the same year he was appointed physician to the queen of George III. His professional avocations now became so numerous and urgent, that he was obliged to take a partner in his lectures, and for that purpose selected his pupil, William Hewson, who afterwards joined Mr. Cruickshank, two gentlemen whose names occupy no unimportant place in the history of practical and structural anatomy.

In 1764 Dr. Hunter began his great and splendid work on the *Anatomy of the Gravid Uterus*, which was not completed till 1775. This gave him a high rank among European anatomists, and foreign and domestic honours abundantly conferred upon him in conse-

quence; but it is to the establishment of his Museum and School, that we are principally to look for the new impulse which was given to the study of anatomy in London, and for the celebrity which this metropolis has since maintained. The account of the origin and progress of this Museum, therefore, deserves to be briefly recorded here. When Dr. Hunter had acquired a competent fortune, the result entirely of his high professional merit and unwearied diligence, he found wealth still pouring in upon him, and became desirous of applying this surplus to some great national purpose of public utility; and what more important or useful than 'A Metropolitan School of Anatomy?' He accordingly, in the year 1765, during the administration of Mr. Grenville, presented a memorial to that minister, in which he requested the grant of an unemployed piece of ground near the King's Mews, at Charing Cross, for the site of his intended building; upon which he undertook to expend 7000*l.*, and to endow a professorship of anatomy in perpetuity. After waiting for some time without a reply, he renewed his request, or rather repeated his proposal; and his second application, which was even in more liberal terms than the former, shared the same supercilious treatment. Although disgusted, as he well might be, at this unaccountable neglect, he determined that the town in which he had acquired his wealth and reputation should not be without some useful and honourable memorial of his labours: he accordingly purchased a piece of ground in Great Windmill Street, near the Haymarket, where he erected a spacious dwelling-house, behind which was a magnificent fire-proof room, fitted up as a museum and library, and communicating with a good anatomical theatre, and an extensive series of apartments for dissection and for the preparation of anatomical specimens. This building was completed in 1770.

Dr. Hunter expended upon this Museum a sum exceeding 20,000*l.*: it included, besides its unrivalled anatomical treasures, a splendid and valuable collection of books, coins, medals, and antiquities; of minerals, shells, and other articles of natural history. By his will, the use of this Museum, under the direction of trustees, devolved upon his nephew, Dr. Matthew Baillie; and in case of his death, to Mr. Cruickshank, for the term of thirty years; at the end of which period the entire collection was bequeathed to the University of Glasgow, together with a sum of 8,000*l.* for its preservation. Dr. Hunter died on March 20, 1783; so that his will, in regard to his Museum, has long since been carried into effect, and it is now in Glasgow. To say nothing of the books, antiquities, and objects of natural history, it obtained, when sent to its final destination, the finest series of anatomical specimens in Europe. Thus, through the apathy of the administration of that day, was this unrivalled collection lost to the English metropolis. Dr. Hunter's munificent intentions must, however,

ANATOMY

never be forgotten: he furnishes a noble and rare example of a man who, as soon as he had rendered himself independent by his own exertion, in a laborious and difficult profession, applied the whole of his large income to a great public object; and, though thwarted in his original desire, that it should remain in the metropolis in which the fortune expended upon it had been amassed, as a monument of his gratitude and an example to his successors, he was, nevertheless, sufficiently liberal and patriotic to devote it to the use of the public, by bequeathing it to the university which had granted him his degree.

Dr. Hunter not only gave a new impulse to anatomical science, the effects of which have been transmitted to the present time, but his zeal in behalf of his favourite pursuit tended to make many converts. Among these, the celebrated John Hunter stands foremost. Hearing of his brother's reputation, he offered his services as an assistant in his inquiries, and his proposal was kindly accepted. Accordingly, in September 1748, he left Lanarkshire, being then twenty years of age. His disposition to excel in anatomical pursuits soon became evident. In the course of the succeeding year he had rendered himself sufficiently master of the subject to instruct his brother's pupils in the dissecting-room; and in 1755 was admitted to a partnership in the lectures. His ardour and enthusiasm as an anatomist were most extraordinary, and he became as eminent in surgery as his brother was in physic: yet his more lucrative professional avocations were never allowed to supersede his scientific zeal; and the result was, the formation of a Museum of Comparative Anatomy, which is at once a memorial of a scientific mind and a skilful hand. Mr. Hunter died suddenly on October 16, 1793, at the age of 65. He directed by his will that his Museum, upon which he had expended nearly the whole of his large professional income, should be offered to the purchase of Government; and, fortunately for the credit of our country, the proposal met with a very different reception to that which we have above recorded in reference to his brother. It was purchased for the sum of 16,000*l.*, and made over, under certain conditions, which have been not only faithfully, but liberally, fulfilled, to the Royal College of Surgeons, in London. It is one of the most splendid collections in the world, and in many respects unrivalled; it is open, under proper regulations, to public inspection, in the magnificent building erected by the College for its reception, on the south side of Lincoln's Inn Fields.

Another convert to anatomical pursuits, educated in the school of William Hunter, was his nephew, the late Matthew Baillie. His virtues and his talents placed him high in public estimation; his anatomical knowledge was the foundation of his professional eminence; and the excellence of his lectures, both as regards matter and manner, tended to exalt the reputation of his uncle's school, and to establish the

importance of anatomy as the basis of medical, no less than of surgical practice.

We have dwelt upon the Hunterian School, from the conviction that it gave a character to anatomical pursuits, which has materially and beneficially influenced their subsequent progress, not only in London, but throughout the kingdom. Their importance and their necessity as the basis of the sciences of medicine and surgery are now publicly felt and acknowledged; the aversion to the dissection of the human body is on the wane; and the degrading and disgraceful practice of allowing the schools of anatomy to be supplied with subjects for dissection by the revolting process of exhumation, has been superseded.

Human anatomy is usually subdivided into *descriptive* and *morbid*, or, more correctly, *pathological*.

Descriptive Anatomy embraces a description of the different organs of the body, together with their relative situations and connections; it examines the textures of which they are formed, enumerates the nerves and vessels by which they are supplied, and gives all general and particular details concerning their organisation. Having done this, it proceeds to the analogies that subsist among the materials of which different organs are composed; and is thus led to specify the proximate constituent parts of the living body.

Morbid or Pathological Anatomy comprehends all that relates to the effects of disease upon healthy structures; and carefully traces and describes the changes of texture and of composition which they thus suffer, in reference to the entire organ, as well as to its individual parts.

We shall now proceed to give a short description of the parts of which the human body is constructed, referring for the account of individual organs to the separate terms under which they are enumerated.

Anatomical teachers generally first direct the student's attention to that branch of the subject which is termed *Osteology*; in other words, to the bones or skeleton, constituting the hardest and most durable part of the whole structure, and that which gives it its stability and general form. At the period of birth, the bones, for obvious reasons, could not exist with the degree of induration and firmness which they possess in the adult; we accordingly find that, at that period, they are mostly soft and flexible, resembling cartilage, with certain specks of osseous matter, which gradually extend and increase, as the process of ossification advances during the growth of the young animal. In contemplating this bony skeleton when it has thus become perfect, we are struck with the admirable adaptation and mutual connection of the various parts of which it consists; the separate bones being extremely numerous (including the teeth, amounting to about 350), and attached to each other by unequal surfaces, the cavities and eminences of which mutually correspond. These connections, termed *arti-*

ANATOMY

culations, are extremely various; some admitting of every variety of motion, others of limited motion, and others, as it were, continuously united. In the former case the evils of friction are perfectly provided against by the peculiarity of the articulating surfaces, which are covered with an extremely smooth and elastic substance, called *cartilage*; and lubricated, or as it were oiled, by a slippery fluid termed *synovia*, which here performs precisely the same office as that of the various anti-attributions which are used in machinery. But as the bones must be more or less restricted in their range of motion, there are peculiar means by which that end is attained: some being prevented from changing their relative situation by certain modes of articulation; others, where a slight motion is required, being united by cartilage; and others, where extensive and varied motions are wanted, being connected by ligaments, membranes, or flesh.—*Ligament* are white, fibrous, glistening, and flexible substances, occurring in an infinite variety of forms and situations. They are, for the most part, exterior to the joint, and, by their great strength and trifling elasticity, preserve the relative position or connection of the bones in their various movements.—*Membranes* are thin, whitish webs or textures, more flexible and elastic than ligament. They not only assist in the security and motion of joints, but fulfil a variety of other offices. They surround or line the cavities and the organs of the body, and contribute to unite and combine the whole; and, at the same time, interpose, and preserve a distinction, enabling separate parts either to co-operate or to act independently of each other. They vary in strength and texture, and different terms are applied to them in different parts of the body: two within the skull are called *matres*; those which envelope muscular fibres are called *aponeuroses*; that which covers the lungs and lines the cavity of the chest is termed *pleura*; that which lines the cavity of the abdomen and its included viscera is named *peritoneum*; those which inclose articular surfaces are termed *capsules*; that which covers bone, *periosteum*; and, in other cases, they are called *coats*, or *tunics*. The remaining substance concerned in the connection of the bones is *flesh*: it is thus that the upper extremities are connected with the body, and that many of the joints are rendered secure. But flesh performs another and more important office, inasmuch as it constitutes a principal part of the organs termed *muscles*, through the medium of which the various movements of the body are effected. Many of the muscles contain, besides flesh, a substance analogous to ligament, through the medium of which they are attached to the bones, and to which the term *tendon* is applied: muscles and tendons are composed of bundles of fibres, which may be unravelled to extreme minuteness; and when what appears to be a single fibre is viewed under the microscope, it resembles a chain of infinitely small globular

particles. But though the muscles are the immediate organs of motion, they are dependent for their powers of contraction and relaxation upon the *nerves* with which they are supplied. These, when separately examined, appear in the form of white cords or threads; and, when traced to their origin, are found to issue as it were from the brain, and from its elongation, termed the *spinal marrow*. The trunks of the nerves are subdivided into branches, and these again into filaments, which enter into, and are, as it were, lost in the substance of the muscles and other organs of the body. Their functions are in some cases obedient to, and in others independent of the will: to the former belong the nerves of the locomotive muscles; to the latter, those of the heart, viscera, &c. When they are divided, the peculiar functions of the organs which they supply are impaired or impeded: thus, the muscles may be deprived of the power of contracting, the glands of secretion, the eye of sight, the ear of hearing, and the skin of feeling. The nervous trunks, which issue in pairs from the brain or spinal marrow, amount to about forty; and in tracing them and their branches, they are found in certain different places to swell into knots, which are termed *ganglia*, or they are reticularly aggregated into *plexuses*.

Having thus shown how the bones are connected and put into motion, and from what sources their motion is derived, it may next be inquired how they and the other organs of the body grow and are nourished. This brings us to consider the blood and its vessels.

The composition and properties of the blood, and the extraordinary changes which it suffers in its passage through the pulmonary vessels, are elsewhere defined. [BLOOD and RESPIRATION.] Without this exposure to the action of the air in the lungs, the blood is unfit for the support of life. We accordingly find that the heart is so constructed as to propel the blood which it receives through the structure of the lungs, and after it has there been aerated, to transmit it over the body: in fact, the heart is a hollow muscle: when it relaxes, its two principal cavities, or ventricles, are enlarged, and the blood flows in; when it contracts, they are diminished, and the blood is propelled into two large tubes or arteries, one leading to the lungs, and called the pulmonary artery, and the other to the system generally, and called the aorta: these arteries are not only elastic, but also muscular, so that they drive the blood onwards from the heart, its retrograde motion being effectually prevented by valves placed at their origin.

The arteries are divided and subdivided into an infinite number of ramifications; and the branches from the same trunk are frequently observed to unite or anastomose in their course; so that when, by any accident, one is obstructed, an adequate supply of blood may be kept up by the others. As, however, the blood cannot return to the heart

ANATOMY

by these vessels or arteries, we find that they inoeculate, or communicate at their extremities with another series of tubes or vessels, which are called veins. These are more numerous than the arteries, and generally accompany them in their course. They have less muscular power; and as they are not assisted by the heart in propelling the blood, they open to it larger and larger channels as it advances, and are supplied with valves by which its reflux is prevented. This is, in fact, the circulation of the blood (first made out by Harvey, as before mentioned); the veins ultimately terminating in two large trunks, which pour the blood into the right auricle of the heart, whence it is propelled into the right ventricle, from which arises the pulmonary artery, transmitting it through the lungs. From the lungs the blood (having been aerated) returns by the pulmonary vein into the left auricle of the heart, which contracting, propels it into the left ventricle, from which arises the aorta. Such then is the extraordinary mechanism by which the circulation of the blood is effected; but it must not be supposed that the whole of the blood is thus directly returned from the arterial into the venous system: a part of it is transmitted by minute arterial ramifications into the different structures and organs of which the body is composed, each of which is gifted with the power of assimilation, that is, of converting the blood, or a part of it, into a substance of its own kind. Some of these minute or capillary vessels also terminate upon the surface of the body, where they exhale perspirable matter; others, upon the membranes lining the cavities of the body, where they secrete the fluids which lubricate and moisten the interior surfaces; and others again go to the glands — those peculiar organs or structures, which have not only the power of separating certain parts of the blood, but of converting it into new forms, which are called secretions, some of which are ejected, others retained, for the purposes of the animal economy.

Thus, then, it appears that the blood nourishes and preserves the body and all its parts, and that it is continually tending to the renovation and reproduction of the different organs; but this very process implies another, and no less extraordinary, function, which is performed by a distinct system; namely, that of absorption. There are, in short, a series of vessels which are continually carrying away the useless and worn-out materials; removing them in a state of solution; furnished, like the veins, with valves; terminating in a common trunk, called the thoracic duct; and pouring its contents into the veins, just before they enter the right auricle of the heart.

It appears, therefore, that a continual system of deposition and removal is in action within the living body; that the ramifications of the arterial system are constantly renovating the different organs, whilst the absorbents are constantly removing the materials of which

they consist. Nothing, therefore, is stationary or permanent; and as the blood, on the one hand, conveys the materials required, so, on the other, it receives those which are removed: and such as are useless, or would be hurtful if retained, are thrown off either by the intestines, the kidneys, the lungs, or the skin. It now only remains to show how this waste is compensated, and by what means those materials which are thrown off in one form are replaced in another. This leads us to the functions of another branch of the animal machinery, called the organs of digestion; those organs, namely, by which the food is converted into blood.

Different animals require different kinds and quantities of food; some living almost exclusively upon animal, others upon vegetable substances; hence their division into carnivorous and graminivorous tribes. Man partakes of both; and, accordingly, the structure of his digestive organs is intermediate between the comparative simplicity of the truly carnivorous, and the complexity of the graminivorous classes. In all the higher orders of animals, however, the mechanism of digestion is of a complicated character.

The first change which the food undergoes is in the mouth, where it is torn, ground, and moistened by machinery expressly adapted to those operations. The teeth are admirably contrived for this purpose; some of them cutting, and as it were mincing, others rubbing and grinding, whilst a fluid is supplied by the salivary glands so as to render the mixture of a proper consistency to be swallowed: this is effected by the organs of deglutition. The food is propelled from the mouth into the tube which conveys it to the stomach, and which is called the oesophagus; it is at the same time prevented, by an extraordinary and complicated arrangement of the parts concerned, from passing in any other direction, and more especially from entering the trachea or air-passage into the lungs. In the stomach the food is subjected to the secretions of that organ, called gastric juice, which is acid, and by which it is gradually converted into a greyish homogeneous semi-fluid substance, termed chyme: so that by the time the food has reached the right end of the stomach, or the pylorus, its original characters are entirely changed; its separate materials are no longer discernible, and it has acquired distinct properties; it is, in short, digested. How these changes are effected we know not, though many attempts have been made to explain them upon chemical and mechanical principles. Dr. Hunter, in his Introductory Lecture, has the following apposite remarks, in reference to this and similar phenomena: 'I must therefore expect,' he says, 'that you will not hereafter be surprised, when you find me avowing great ignorance in many of the most considerable questions relating to animal operations, such as sensation, motion, respiration, digestion, generation, &c. In my opinion, all these subjects are much less understood than most people think them. Our vanity deceives us, and persuades us that we

ANATOMY

have got the whole as soon as we have acquired a smattering of natural knowledge. Hence it is that the different sects of physiologists have endeavoured to explain animal functions upon such different principles. Hence, for example, to account for digestion, some have made the stomach a mill; some would have it to be a stewing-pot, and some a wort-trough; yet, all the while, one would have thought that it must have been very evident that the stomach was neither a mill, nor a stewing-pot, nor a wort-trough, nor anything but a *stomach*.

When the food has been thus far digested in the stomach, it passes into the duodenum, or upper end of the intestinal canal; a tube, the whole length of which is about six times that of the body, and which, therefore, is variously and strangely convoluted to enable it to be packed into the abdominal cavity. Into this portion of the intestines various vessels and glands deliver their secretions, partly for the purpose of lubricating its surface, and partly to assist in the further changes which are to be brought about in the chyme. Of these fluids, two are especially remarkable, from the importance and size of the glands by which they are secreted, and of the ducts by which they are conveyed; namely, the *bile*, which is of a green colour and bitter taste, and is secreted in the liver; and the *pancreatic juice*, which appears to resemble saliva, and which is secreted by a gland called the pancreas. The influence of these fluids upon the chyme is direct and important: the pancreatic secretion probably acts as a diluent merely; but the effect of the bile is more complicated; and it appears to be essential to the further change of the chyme into *chyle*, which is a white milk-like fluid, formed in the upper part of the intestine, and absorbed by a distinct set of vessels which, from the colour of their contents, have been called lacteals, and which convey the chyle, that is, the portion of the products of digestion fitted for nutrition, into the above-mentioned trunk of the lymphatics, whence it is transmitted into the veins, which open through the medium of the right auricle into the right ventricle of the heart. The bitter principle of the bile, and its colouring matter, are obviously not absorbed by the lacteals, but remain with the residue of the food, which is slowly propelled along the whole of the intestinal tube, and, having undergone certain changes in its passage, is ultimately voided as excrementitious.

Having now enumerated the various classes of organs in the human body, and adverted to their leading functions; having seen how the bones are united by articulations, and connected by ligaments, flesh, and membranes, forming a variety of levers adapted to the motions of the limbs, and supporting and protecting the soft parts, as in the skull and spine; how the brain and nerves are concerned in the sentient energies, and in presiding over and directing muscular motion, and influencing the functions of the viscera; having likewise seen how each part of the body is nourished by the blood, which is sent

from the heart by the arteries, and conveyed back to it by the veins; how the useless and decayed parts are removed by the lymphatics; how the nutritious part of the food is carried into the blood by the lacteals; and how venous is changed into arterial blood in the course of its passage through the pulmonary vessels; it only remains to observe, that the whole fabric is as it were protected from external injuries by its *integuments*. Of these the most exterior is a covering, varying in thickness and induration on different parts of the body, but everywhere without feeling, and called the *epidermis*; immediately beneath it is a soft mucous substance termed *rete mucosum*; and under it the *cutis*, or true skin. These external coverings of the body are attached to and connected with the parts beneath, by cellular membrane. But though the animal owes much of its general security to these textures, it owes more to the senses, instincts, and appetites with which it is so miraculously endowed. 'By these it is led to pursue what is useful, and to guard against danger, inconvenience, and want. Nor is this all; there has likewise been conferred, to a certain extent, upon all living bodies, the power of reproduction, by which they are frequently able to repair the slighter injuries to which the different organs are exposed; and if this power be exceedingly languid in the latter periods of old age, it is because the author of nature never intended that the animal structure should be immortal. He has fixed its bounds, which it cannot pass; and has measured out the time when the fairest fabric must crumble into dust, and its animating spirit return unto Him, the great Almighty Incomprehensible Being, who first bestowed it.'—Dr. Barclay's *Introductory Lectures to a Course of Anatomy*; and see Dr. William Hunter's *Two Introductory Lectures*, for details respecting the history, uses, and importance of the study of Anatomy.

ANATOMY, COMPARATIVE. So called because the organisation of the lower animals was first principally studied with immediate reference to that of the human subject. Galen, who visited the schools of Alexandria at a period when the dissection of the human body was no longer permitted, sought in the anatomy of the ape to acquire a vicarious knowledge of the anatomy of man. Vesalius, after the revival of literature, dissected various quadrupeds, and compared their organisation with that of man, in order to correct the errors of Galen, and to establish the true knowledge of the peculiarities of the human structure.

Succeeding anatomists have investigated the structure of the lower animals, to acquire the knowledge necessary for experimenting upon them with success; and still more important discoveries in physiological science have resulted from tracing the modification and disappearance of different organs in the descending series of animals, as the only means by which we can obtain just notions of the uses and relative importance of the different organs in the animal economy, and a perception of the laws which

ANATROPAL

regulate their co-existence in the same individual.

Aristotle, Harvey, and Hunter combined the investigation of the mature animals of different classes with observations of the different stages of development of the embryo, and their example has been assiduously and successfully followed by the ablest comparative anatomists of the present day, whereby some of the general laws of animal organisation, of development, and of the analogies which apparently different parts bear to one another throughout the great scheme, have been discovered.

A very important application of comparative anatomy is to the determination of the relative degrees of complexity in the organisation of different animals, and of the number and value of the points of resemblance which different species manifest to each other in the totality of their organisation. A study of the anatomy of animals, guided by these views, is essential to the determination of their natural affinities, which is the highest aim of the philosophic naturalist.

Lastly, the labours of the comparative anatomist continually tend to bring to light examples of structures, designed with reference to especial purposes, of the most striking and forcible description; and thus provide for the moralist and divine a storehouse of facts peculiarly adapted to the illustration of the doctrine of final causes. [BIOLOGY; MORPHOLOGY; TELEOLOGY; DEVELOPMENT.]

Anatropal or Anatropous (Gr. *ἀνὰ πρὶς, invert*). A very common kind of embryo, produced by one side of the ovule growing upon itself, while the other remains immovable, till at last that part of the ovule which was originally next the apex, is brought down to the hilum, the base of the nucleus in such cases being at the apex of the ovule. The common apple, and the greater part of plants, offer examples of this.

Anauxite (Gr. *ἀναύξητος, without augmentation*). A mineral of a greenish-white colour, which occurs massive and granular at Bilin, in Bohemia. It is composed of silica, with much alumina, a little magnesia and protoxide of iron, and 11.6 per cent. of water.

Anchor (Gr. *ἄγκυρα*). Consists of a straight bar, called the shank, A B, which ends in two arms, B C, B D, on which are placed the triangular plates called flukes, or palms; the extremity E or F is called the pea (peak) or bill; the point B is called the crown. At the end A is placed the stock G H, which, when of wood, consists of two pieces of oak, hooped together. When the stock is of iron, it passes through a hole in the end of the shank. The stock is at right angles to the plane of the flukes, and is a little longer than the shank. At A is the ring, which is of iron,

ANCHOR

to which the cable is attached, and by which the anchor is lifted or hung.

When a hemp cable is used, the ring to which it is bent (fastened in a particular way) is covered first with tarred canvass, and then with pieces of rope secured firmly round it; this is called a puddening, and protects the hemp from the iron. When a chain cable is used, it is shackled to the ring, which is not then puddened.

Men of war and large ships carry two large anchors of equal size, at the bows, called, thence, bower anchors; and two others, of the same size, called the sheet and the spare anchors: besides two or three others, which are much smaller, for temporary occasions.

The anchor, after being let go from the ship's bow or side, whether the shank be vertical or horizontal when it enters the water, arrives upright at the bottom, in consequence of the resistance of the water on the stock, when it falls over, and rests on the crown, one corner of a fluke, and the end of the stock. From this position of stable equilibrium on three points, forming a long narrow triangle, a small force disturbs it, when the stock, falling flat, one of the bills must pierce the ground, penetrating deeper as the cable pulls, until the arm is partly or entirely buried.

Since the security of the vessel depends on the hold the anchor has of the ground, it is evident that the direction of the fluke should be such that the reaction of the soil against it, from the pull of the cable, may tend most effectually to keep it down.

The pressure on the fluke being perpendicular to the surface, take A B to represent the pull of the cable, then the resolved portion of this perpendicular to the fluke is $BC = AB \cos. ABC$; and the effect of this in keeping the fluke down is $BD = BC \cos. CBD = BC \sin. ABC$, because A B is horizontal, and B D vertical, CBD is $90^\circ - CBA$; hence $BD = AB \sin. A B C \cos. A B C$, which is maximum when $A B C = 45^\circ$. The flukes of anchors in general make the angle with the shank much greater than this; but Lieut. Rodger, R.N., has, among other improvements, adopted this angle in his patent anchor, having established the above conclusion by experiment.

Anchors are made of broad flat bars forged together. As the greatest strain upon the shank takes place during the act of weighing, the diameters of the shank are made unequal, the longest being placed vertical. This improvement is, we believe, due to Mr. Pering, on whose plan anchors have of late years chiefly been made.

The weight of an anchor in men of war is estimated roughly at about 1 cwt. to gun; in merchantmen, about 1 cwt. for each 15 tons. The weight of the anchor is not strictly proportional to the size of the vessel, as large vessels are less affected by sudden or violent motions than smaller ones are. Large anchors are thicker in

H

ANCHOR

proportion to their length than smaller ones, that is, the weight increases faster than the cubes of the dimensions.

When an anchor is left behind, it is recovered either by lifting it by the buoy rope, or, where that is not possible, by sweeping for it; which is dragging a hawser, hung between two boats, slowly over the bottom till it catches the upper fluke, by which the anchor is then weighed.

When one anchor is down the ship is said to be at single anchor; when two are down, the ship is generally moored. [MOORED; CABLE; BUOY.] Ships rarely ride by more than two anchors; in bad weather a third is often let go under foot, as a precaution in case of one of the cables parting.

When the anchor is dragged by the pulling of the cable, it is said to come home. When the cable gets twisted round the anchor or stock, the anchor is said to be foul. The anchor is sometimes hove up without one of the flukes, which has either been fixed in a cleft of a rock and wrenched off by the force of weighing, or been snapped off by striking against a point of rock in its rapid descent.

When the ship is at single anchor, the wind or tide may carry her over the anchor; if the water is deep, she may so drag the cable as to foul the anchor, in which case it may not hold again: if the water is very shallow, she may get upon the anchor, the fluke entering the ship's bottom, or she may break the shank by striking upon it. Keeping the ship clear of her anchor is, therefore, an important, as it is also a nice point of seamanship.

When the anchor is lifted out of the ground, it is said to be aweigh; when hove up to the surface of the water, it is awash. The anchor being hove up by the cable only to the hawse holes, is lifted by the ring to the cathead: this is called *catting* it. The fluke next the ship's side is then lifted up to its resting-place, called the bill board: it is now said to be fished. When the ship is fairly at sea, the ring is lashed close up to the cathead, and the fluke brought close to the ship's side, or inside the bulwark, and the cable and buoy rope unbent: the anchor is then secured.

ANCHOR. In Architecture, an ornament applied to mouldings somewhat resembling an anchor, intermixed with eggs, and by some called a tongue, from the resemblance it bears to the forked tongue of a serpent. It is found in the mouldings of all the orders, but is only applied to that called the echinus, or quarter round; a singular illustration of it is to be met with in the tower of Layer Marney, in Essex. The term is also applied to the wrought iron ties which are inserted in the cross walls of buildings that have a tendency to separate, the heads of such ties being generally formed by large circular plates; but in the structures of the middle ages they were made in the form of letters, or figures, so as to represent the dates of their insertion. The term anchor is also applied frequently to the portion

ANCILE

of a collar used for a lock-gate where it rests entirely in the wall.

Anchorage. Ground fit to hold a ship's anchor, so that she may ride safely. The ground best suited for this purpose is hard sand, or stiff clay; and the best position is that which is land-locked, or out of the tide. The harbour dues paid by ships for casting anchor, are also called *anchorage*.

Anchorite (Gr. ἀναχωρητής, from ἀναχωρεῖν, *I retreat*, or *withdraw*). More properly, an anchorite; a hermit, or person who has retired from the world with the purpose of devoting himself entirely to meditation and prayer. Such was the case with many of the early Christians, beginning, perhaps, with such as fled from the persecutions of Decius and Diocletian. The adoption of perfect solitude was essential to the character of an anchorite: but they were not necessarily bound by vows. The origin of this class of religionists preceded that of the Cœnobites, or monks living in societies; but in later times the monks used frequently to leave their monasteries, with the permission of their superior, and devote themselves for a time, or for their whole lives, to the solitude of anchorites.

Anchorvy. [ENGRAULIS.]

Anchorusa (Gr. ἄγκυρα). A Boraginaceous genus of Southern Europe and the East, which yields the alkanet, *A. tinctoria*, a dye plant, now sometimes called *Alkanna tinctoria*. The root, which is thick in proportion to the size of the plant, is the part used, and yields a red dye readily extracted by oil and spirits. It is said to be also used for colouring some of the mixtures dignified with the name of port wine.

Anchoric Acid, Anchorusine. The red colouring matter of alkanet root. It is soluble in oils and fats.

Anchylosis (Gr. ἀγκύλωσις, from ἄγκος, *a bend* or *hollow*). A stiff, immovable, or bent joint.

Ancient Domesne. In Law, all lands which, having been in possession of Edward the Confessor, and from him having passed to William the Conqueror, and named in Domesday Book as Terra Regis, are said to be held in ancient demesne. The tenure is peculiar, resembling copyhold in some respects.

Ancients (Fr. anciens). Gentlemen of the Inns of Court and Chancery. The Inns of Chancery consist of ancients, and students or clerks. The ancients of Gray's Inn are the oldest barristers, and those of the Middle Temple are those who have passed their readings.

ANCIENTS, COUNCIL OF. In French History, one of the two assemblies composing the legislative body in 1796. It consisted of 250 members, and derived its name from each of them being at least forty years of age. It was put an end to by the revolution of the 18th Brumaire.

Ancile (Lat.). In Roman antiquities, the shield of Mars, which, according to tradition, fell from heaven in the reign of Numa, and was accompanied by an oracle, which declared that,

ANCIPITAL

while it remained in Rome, the city could never be taken. Its figure was that of an oval compressed in the middle. The legend adds that Numa entrusted the care of it to the Salii, or priests of Mars, in whose temple it was placed, and that he had eleven more shields made to exactly the same pattern, in order to prevent the genuine one from being distinguished and stolen. Every year, on March 1st and for many successive days, these ancilia were carried round the city by the Salii, with solemn dances and music.

Ancipital (Lat. *anceps*, two-edged). When anything is compressed, with the two opposite edges thin. It is chiefly applied in Botany to leaves and stems.

Ancistrocladus (Gr. *ἄγκιστρον*, a hook, and *κλάδος*, a branch). A natural order of Eragrostaceae, containing only the genus *Ancistrocladus*, an Indian climbing plant, of botanical interest only.

Ancona. An old Venetian term used to express a picture, image, or altar-piece; it occurs in old documents, and is a corruption of the Greek *εἰκὼν*, an image, picture, or portrait. (Floriol, *Geschichte der Zeichnenden K. etc.*, &c., vol. ii. p. 6, Göttingen, 1801.)

Andalusite. An anhydrous silicate of alumina, named after the province of Andalusia, in Spain, where it was first noticed. It may be distinguished from Felspar by its greater hardness and infusibility. It occurs in slightly rhombic four-sided prisms, sometimes in a compact form with a granular or columnar structure, of a reddish colour passing into pale grey, with a vitreous lustre, and is transparent, or translucent, at the edges. Andalusite is found most frequently in micaceous schist, and in gneiss; less frequently in granite, serpentine, and quartz rock, in Aberdeenshire, Banffshire, the Shetlands, Donegal and Co. Wicklow in Ireland, the Tyrol, Saxony, Moravia, Bavaria, Siberia, Connecticut, Massachusetts, &c.

Andante (Ital. *going*). In Music, is a direction for the time, or rather for the style in which a piece is to be taken. It is moderate, rather slow, but distinct and flowing.

Andes. This magnificent chain, including some of the loftiest mountains of the globe, rises from the shores of the Pacific Ocean, and runs parallel to the South American coast, commencing at Cape Horn and reaching to the Isthmus of Darien. At first, a single narrow range for a distance of 2600 miles, it then for another 2000 miles (the rest of the distance) becomes triple, the three parallel ridges being connected at intervals by narrow cross ridges forming *knots*, generally remarkable for extremely lofty mountain peaks, high table lands, and plains and elevated lakes. Near these knots the great rivers of South America take their rise. In absolute length no single chain in the earth approaches the Andes, and only a few of the higher peaks of the Himalayan chain rise higher above the sea level.

By the knots above mentioned the northern chain of the Andes is divided into several

ANDESINE

portions, of which the two most to the south (terminating the Bolivian Andes) are of extraordinary elevation, and are connected with the lofty plateau and lakes mentioned in the article America. From these plains rise the higher elevations, attaining the height of about 26,000 feet on the eastern or interior range, and about 22,000 feet on the western or coast range. The snow line of the chain in this latitude is about 17,000 feet. To the north the Andes of Peru are less elevated, and terminate in the knot of Loxa, whence rise the principal sources of the Amazons river, under the name of Marañon. This point is less than 8000 feet above the sea, and is one of the lowest in the chain until we approach the Isthmus of Darien. Beyond it the mountain peaks rise again to upwards of 20,000 feet, the cone of Chimborazo towering over all in the neighbourhood. This part is called the Andes of Quito. Further north the mountains are more distributed and somewhat less lofty.

There are many passes across the Andes, but they are mostly at high levels, and only accessible at certain seasons. On the eastern side the slope is more gradual than on the western, and terminates in plains of greater elevation, or in flanking ranges of hill or mountain. In the Bolivian Andes the passes are from 14,000 to 16,000 feet above the sea.

Very many of the higher peaks of the Andes are conical and volcanic, but only a few are active volcanoes. Of these Cotopaxi, near Quito in the Andes of Quito, is one of those that has most frequently been described in modern times. Its height is estimated at 18,880 feet. This and the still higher elevation of Chimborazo (21,420 feet) are situated one or two degrees south of the equator. Pichincha is the name of another of the principal elevations, celebrated for having served as a signal in the measurement of an arc of the meridian by Bouguier and La Condamine. It is actually under the equator.

Little or no rain falls on the western or Pacific side of the Andes, except in the temperate latitudes near the southern extremity. In that part, however, there is not only rain, but extensive glaciers, which come down near the sea, and penetrate below the limits of the palm tree and other tropical and sub-tropical vegetation. Nothing can surpass the desolation of these regions. Further north in the Andes of Chili there are a number of volcanoes, and some extremely lofty peaks, Aconcagua, near Valparaiso, rising to 23,200 feet (as much as 10,600 feet above the snow line in that latitude).

In the higher plains of the Andes there are remarkable atmospheric effects, the landscape being without much colour, although the sky is generally quite cloudless. This arises no doubt from the thinness of the air. Changes of weather are sudden and violent, and the storms, both electric and of wind, are singularly destructive and terrible.

Andesine. A lime-and-soda Felspar resembling Albite, and entering into the compo-

ANDIRONS

sition of the rock Andesite, which occurs in the Andes of South America.

Andirons. The term used by the mediæval authors to express the fire dogs which were used in places where wood was burnt. They were often made highly ornamental, and were adorned with silver and plated extremities of the most elegant character.

Androsaceæ (Andrea, one of the genera). Little moss-like plants, differing from the true mosses in the want of an operculum and peristome, and in having four-valved spore-cases.

Andreasbergolite. A name given to Harmotome, after Andreasberg in the Harz, where it was first discovered.

Andrena. The name of a Fabrician genus of bees, including those which have the tongue three-cleft, and the labium cylindrical, with two membranous bristles on each side.

Androecium (Gr. *andros*, a male, and *eikos*, a house). All that part of a flower to which the male organs appertain. The ring of stamens in a plant is an androecium; so is the fringe at the mouth of the tube in the passion flower, taken together with the true stamens. The term may be literally translated the male apparatus.

Androgynous (Gr. *andros*, from *andros*, a man, and *gynê*, a woman). In Botany, a union of both males and females, either in the same flower, which is also called hermaphrodite, or upon the same plant, the sexes being in different flowers, as in the birch and similar trees. The latter is what Linneus called monœcious.

ANDROGYNOUS. In Physiology, the possession of the organs of both sexes in the same individual, either naturally, as in the snail; or preternaturally, as in the free martin and similar monsters. An hermaphrodite.

Androïd (Gr. *andros*, man, and *eidos*, form). An automaton which imitates the actions of man. [AUTOMATON.]

Andromeda (after the virgin Andromeda, daughter of Cepheus and Cassiope). A family of Ericaceous shrubs, many of which are cultivated for the sake of the flowers. The type species is *A. polifolia*, a dwarf plant possessing acrid narcotic properties, and found wild in boggy situations in some parts of England.

Androm (Gr.). In Architecture, the suite of apartments exclusively occupied by the male part of the establishment. [ΓΥΝΕΚΕΙΟΝ.]

Androphorum (Gr. *andros*, a man, or, in Botany, a stamen, and *phoros*, to bear). A columnar expansion of the centre of the flower, on which the stamens seem to grow, as in the passion flower. In reality, it is formed partly of the adhering filaments, and partly of an elevation of the growing point.

Andropogon (Gr. *andros*, a man, and *pogon*, a beard). A genus of tropical grasses containing *A. Schenanthus*, the sweet-lemon-grass, which yields one of the fragrant lemon-scented grass oils; *A. Calamus-aromaticus*, considered to be the sweet cane of Scripture; and *A. (Anatherum) muricatus*, the aromatic khus of India, and vetiver of the French.

ANEMOMETER

Anecdote (Gr. *anekdoron*, something unpublished). In its original sense, some particular relative to a subject not noticed in previous works on that subject. In its secondary sense, the narrative of a particular action or saying of an individual.

Anellata, Anellides (Lat. anellus or anellus, a little ring). Sometimes written *annelidans* or *annelides*. A class of articulate animals, with a long cylindrical body, divided into ring-like segments, having red blood, and respiratory organs, but no jointed extremities. They are classified as follows:—

Order Suctoria . Leeches		
<i>Terricola</i>	{ Earthworms, Naiads.	= Abranchia.
<i>Errantia</i>	{ Nereids, Sea-centipedes, Lugworms, & Sea-mice.	= Dorsibranchiata.
<i>Tubicola</i>	. Serpulans	{ Cephalobranchiata.

Analytrens (Gr. *ἀνάλυτρος*, from *ἀν*, priv., and *λυτρος*, a sheath). A name sometimes given to those insects which have two or four membranous wings, either naked or covered only with hairs or scales.

Anemometer (Gr. *ἀνέμος*, the wind, and *μέτρον*, measure). An instrument for measuring the force or velocity of the wind.

Dr. Lind's anemometer consists of a glass tube, bent into the form of the letter U, and open at both extremities. One of the extremities, A, is also bent round to the horizontal direction, in order that the wind may blow into it. The tube being partially filled with water and exposed to a current of air, the water in the branch at which the wind enters is depressed, for example, to B, and consequently rises in the other branch to C, and the difference, *b C*, of the levels at which it stands in the two branches is the height of a column of water, the weight of which forms a counterpoise to the force of the wind. The relative velocities of the wind are thus ascertained, the variation of the velocity being nearly proportional to the square root of the resistance. The bore of the tube is diminished at the bottom to check the undulations of the water caused by a sudden gust of wind. This instrument may be mounted on pivots, and an arrow-shaped vane attached, so that the mouth A shall be always exposed to the direct current, and thus the direction as well as the velocity of the wind indicated at the same moment.

But the anemometer most generally used is one devised by Dr. Robinson, of Armagh, and made by Casella, of London. It consists essentially of four hemispherical cups, having their diametral planes exposed to a passing current of air; they are carried by four folding horizontal arms attached to a vertical shaft or axis, which is caused to rotate by the velocity of the wind.

Dr. Robinson found that the cups, and consequently the axis to which they are attached, revolve with one third the wind's velocity. A simple arrangement of wheels and screws is appended to the instrument, which, by means of two indices, shows on inspection the space traversed by the wind in a given time.

Whewell's registering anemometer consists of a series of wheels and pinions carrying a tracing pencil which is set in motion by a small fly connected with an ordinary vane. The pencil descends $\frac{1}{2}$ th of an inch for every 10,000 revolutions of the fly, and presses against a cylinder carrying a registering paper.

Casella, by an elaborate combination of Robinson's anemometer with some recent modifications, has produced an instrument capable of registering the direction and velocity of wind with even greater accuracy than any of the above. A specimen of this anemometer was shown at the International Exhibition of 1862; its indications may be recorded in any room of the building on which it may be placed.

Anemometry. The operations connected with ascertaining and recording the direction, velocity, and other attributes of wind. [ANEMOMETER.]

Anemone (Gr. from *ἀνέμος*, *wind*). A genus of Ranunculaceae herbs, mostly perennials, many of them cultivated in gardens for the sake of their handsome cup-shaped flowers. The most showy is that known as the poppy anemone, *A. coronaria*. Many of them have tuberous or thickened roots.

Anemonic Acid. A solid organic compound existing in the wood anemone.

Anemonin, or Anemonia. An acrid crystallizable substance obtained from some species of anemone. It burns like camphor.

Anemoscope (Gr. *ἀνέμος*, *wind*, and *σκοπέω*, *I look*). An instrument for indicating the direction of the wind. A common vane, or weathercock, is an instrument of this kind. Sometimes the vane turns a spindle which descends through the roof of the building into the chamber where the observation is to be made. An index fixed to the spindle points out the direction of the wind, on a compass card fixed to the ceiling. By means of wheel-work, the direction of the spindle, or the axis of the index, may easily be changed, so that the compass card may be placed on a wall of the chamber, or in any convenient position for observation.

Aneroid Barometer (Gr. *ἀ*, *without*, and *νόσος*, *wet, damp*, to distinguish it from the ordinary mercurial barometer).

The instrument may be described as consisting of three essential parts: first, an airtight box formed of thin metallic plates, so that the sides yield to the pressure, and collapse when the air is withdrawn from the interior; secondly, a spiral spring resisting the compression of the sides of the box; and thirdly, a system of levers connected with the box and spring, and giving motion to an index

by which the amount of pressure is exhibited on a scale. The arrangement is represented in the annexed diagram, in which A represents the vacuum-box, B B the main lever, C the

fulcrum or support, and S the spring; the direction of the forces being indicated by the arrows. If, at a certain pressure, the lever has the direction indicated in the figure, then, supposing an increase of pressure to take place, the upper side of the box will be pressed downwards, carrying the lever, with which it is shown to be in connexion, along with it, and consequently compressing the spring against which it acts. The lever, it will be observed, is of the second order, and, as usually constructed, the distance of the spring from the fulcrum is to that of the box from the fulcrum in the ratio of six to one.

The box is of a cylindrical form, about 2½ inches in diameter, and 5-16ths of an inch deep, partially exhausted of air, and hermetically sealed. It is composed of thin corrugated copper-plates. The spring is formed of steel wire, about 1-20th of an inch in thickness, and the helix or coil is about an inch in height, and 5-8ths of an inch in diameter. A system of levers is employed to multiply the movement of the main lever, and to the ultimate lever is attached a piece of fine watch-chain pressing round a small roller, on the axis of which the index is placed, which exhibits the variations of pressure on a graduated dial. The index is kept in its place, and the chain in a state of tension, by means of a delicate spiral spring attached to the same axis. The whole is placed within a cylindrical box, about five inches in diameter, and the general form of the instrument resembles that of a watch.

Anethum (Gr. *ἀνθον*). This genus of Umbelliferae contains the common dill, *A. graveolens*, a slender fennel-like plant, with umbels of small yellow flowers succeeded by thin flat fruits, which yield up their carminative properties on distillation. Dill-water is a well-known domestic remedy for flatulency.

Aneurism (Gr. *ἀνέκρουμα*, from *ἀνεύρω*, *I dilate*). A tumour formed by the morbid dilatation of an artery, and which is therefore distinguished by its pulsatory motion.

Anfractuous (Lat. *anfractus*, a winding, or curve). In Botany, when the lobes of an anther, or the margin of any part, is folded back upon itself, and doubled and bent till all trace of its normal character is lost. The anther of a cucumber is anfractuous.

Angiology, or Angiology (Gr. *ἀγγειον*, a vessel, and *λόγος*, a discourse). The doctrine of the vessels of the body.

Angel, Golden, or St. George, or St. Constantine. An ancient order of knight hood, fabulously reported to have been insti-

ANGEL-WATER

tuted by Constantine, but probably by the imperial house of Comnenus at Constantinople, and revived by the Emperor Charles V. The grand mastership of this order was resigned by the last representative of the house of Comnenus to that of Farnese, dukes of Parma.

Angel-water. A mixture of rose, orange-flower, and myrtle water, perfumed by musk and ambergris. It is made in Portugal.

Angelic Acid. A solid white crystalline body, found in angelica root. It may be formed by heating oil of chamomile with a caustic alkali.

Angelic Ether. A compound of angelic acid and ether.

Angelica (Gr. *ἄγγελος*, *angelio*, from its supposed virtues). A tall growing Umbelliferous plant, found on the banks of rivers, and in other watery places. It grows four or six feet high, and has large compound leaves. The stalks are hollow.

Angelicin. A neutral substance found in angelica root.

Angels (Gr. *ἄγγελος*, a messenger). Spiritual beings ministering to God. In the Scriptures they appear as messengers, by whom God conveys his commands to men. We read also of the devil and his angels. See Milman, *Lat. Christianity*, b. iv. c. 2.

Angina (Lat. from *ango*—Gr. *ἄγω*, *I strangle*). A disease attended with a sense of anxiety and suffocation. The term is commonly applied to certain symptoms arising from organic disease of the heart, which gives rise to a distressing difficulty of respiration, and is hence termed *Angina Pectoris*.

Angiocarpous (Gr. *ἄγγιον*, a vessel, and *καρπός*, fruit). When seed-vessels are inclosed within a covering that does not form a part of themselves, as the filbert, covered by its husk, or the acorn seated in its cupule. The word is also applied sometimes to such fungi as have their spores included in a peridium, or hollow-shell, as *Lycoperdon*.

Angiospermous (Gr. *ἄγγιον*, and *σπέρμα*, seed). When seeds are inclosed within a pericarp, as in most plants. The word is now chiefly used in opposition to gymnospermous, which means that seeds are not included in a pericarp, as in fir-trees and others. Linnæus intended to apply it in the same sense; but he contrasted it with small-lobed seed-like fruits, which he mistook for naked seeds.

Angiosporous (Gr. *ἄγγιον*, and *σπορά*, a seed). A term applied to such fungi as *Lycoperdon*, which have their spores inclosed in a hollow shell or bag.

Angiotomy (Gr. *ἄγγιον*, and *τέμνω*, *I cut*). The dissection of vessels.

Angiarite. A fibrous and compact phosphate of iron, of a grey colour inclining to blue, which is found at Anglar, dept. of the Haute Vienne, in France.

Angle (Lat. *angulus*). In Geometry, there are several kinds of angles; the simplest, and the one to which all others are referred, is a *rectilinear angle*, which, according to Euclid, is

ANGLE

'the inclination of two straight lines, which meet, but have not the same direction.' The point of meeting is called the *vertex* of the angle, and the lines themselves its *sides*. A clearer conception of an angle as a *magnitude*, however, is obtained by considering it as the *quantity of turning* around the vertex, which would have to be applied to one side in order to make it coincide with the other. To this it might be objected that the coincidence in question could be brought about by very different quantities of turning. The rotation, for instance, might be *direct* (like the hands of a watch) or *retrograde*, or it might be arrested at the first, or at any subsequent coincidence. This absence of strict definition, which might easily be remedied if desired, has, however, its own advantages, especially in trigonometry. Euclid always understands by the angle between two right lines the *least quantity of rotation* necessary to produce coincidence. The quantity of turning necessary to make a line coincide with its continuation has been called an *angle of continuation*; half of this is a *right angle*.

In the ordinary measurement of an angle, a complete rotation is supposed to be divided into 360 equal parts called *degrees* (°), each degree being subdivided into 60 equal parts called *minutes* (′), and each minute again into 60 parts, termed *seconds* (″).

The theoretical, or, as it is called, the *circular measure of an angle*, instead of being a *concrete* is an *abstract* number. A circle is conceived to be described around the vertex, and the *ratio* of the arc, intercepted by the sides of the angle to the radius of the circle, is taken as the measure of the angle. The assumption is justified on the ground that the ratio in question does not depend upon the magnitude of the circle, whilst for one and the same circle this ratio is proportional to the arc, and, therefore, to the angle at the centre standing on that arc.

According to the above definition the theoretical *angular unit* will be the angle at the centre which is subtended by an arc equal to the radius. The circumference of a circle being times its diameter or 2π times its radius (where π represents the number 3.14159, &c. [CIRCLE]), π will be the circular measure of two right angles or 180° , and if A be the number of degrees in any other angle, whose circular measure is θ , we have the following simple formula for converting ordinary into circular measure, or *vice versa*:

$$\frac{A^\circ}{180^\circ} = \frac{\theta}{\pi}.$$

ANGLE OF CONTACT. Called also *angle of contingence*; it is the infinitesimal angle between the rectilinear tangents to a curve at two consecutive points. When the curve is traced on a surface, the angle between two geodesic lines touching the curve at consecutive points is called the *geodesic angle of contact*. [CURVATURE, GEODESIC.]

ANGLE OF CURVATURE. The angle between

ANGLE

two consecutive normals of a plane curve; it is always equal to the angle of contact.

ANGLE, CURVILINEAR. In Geometry, the angle formed by the tangents to two curves at the point where the latter meet.

ANGLE, DIHEDRAL. In Geometry, the angle formed by two planes which intersect; in other words, the quantity of turning, around the line of intersection, which would be requisite in order to make one plane coincide with the other.

The angle between a right line and a plane is the quantity of turning, around the point of intersection and in a plane perpendicular to the given one, which would be required to make the line lie in the plane.

ANGLE, FACIAL. In Zoology, signifies the angle made by the intersection of two lines drawn, the one from the most prominent part of the frontal bone over the anterior margin of the upper jaw, the other from the external orifice of the ear-passage along the floor of the nasal cavity.

The internal angle of Walther was described by two lines, the one from the occipital protuberance to the *crista galli*, the other from the glabella to the root of the nose. The external angle of Mulders was formed by the intersection of Camper's facial line, with another from the basioccipital bone to the root of the nose. Daubenton's angle was described by a line going from the inferior margin of the orbit from the posterior region of the occipital foramen intersecting another following the direction of the foramen. Doornick's incisivo-occipital line was obtained by dropping a vertical line to the level of the meatus auditorius externus, crossed by another from the incisor teeth to the occipital protuberance.

ANGLE, FRONTAL. In Ornithology, signifies the angle which the culmen, or upper line of the beak, makes with the forehead.

ANGLE OF JAW. The point of intersection between the ascending and the horizontal rami of the jaw is so called. In the marsupial mammalia it is inflected inwards. The bone *angularis*, which forms this angle, is separately ossified in the lower *Vertebrata*.

ANGLES OF INCIDENCE AND REFLECTION. Terms used in Optics. [REFLECTION.]

ANGLE, SOLID. According to Euclid, 'a solid angle is that which is made by the meeting of more than two plane angles, not in the same plane, in one point.' This definition, however, is incomplete as well as vague. For we also speak of the solid angle at the vertex of a cone, and measure the same by the ratio, to the whole surface of a sphere around the vertex, of the portion of this surface intercepted by the cone.

ANGLE, SPHERICAL. In Trigonometry, the angle between two great circles of a sphere, or the inclination of the planes of these circles to each other. A spherical angle is measured by the arc of a great circle intercepted between those two points of its sides which are at the distance of 90° from the point of intersection, or the vertex of the angle.

ANGUSTURA BARK

ANGLE, VISUAL (Optics). The angle formed by two rays of light, or two straight lines drawn from the extreme points of an object to the centre of the eye. The apparent magnitude of objects depends on the magnitude of the angle under which they are seen; nevertheless, in observing distant objects, our ideas of their magnitude are greatly modified by the judgment which we form of their distances. [MAGNITUDE, APPARENT.]

Angle Iron. The piece of iron which is rolled to the shape of the letter L, intended to form the joints of plate iron for large girders or for the joints of boiler plates, &c., to which the angle iron is riveted by single or double, or chain riveting.

Angiometer. This name has been specially given to an instrument used by geologists for measuring the dip of strata, the angles of joint-planes, &c. (*British Association Reports*, 1847.)

Anglesite. A sulphate of lead produced by the decomposition of galena. It occurs in rhombic prisms, with dihedral terminations, and of a white, grey, or yellowish colour, but frequently tinged blue or green by oxide of copper, in Derbyshire, Cumberland, Leadhills in Lanarkshire, and Wanlock Head in Dumfriesshire; also in Baden, Siegen in Prussia, Silesia, Siberia, the Harz, Spain, and a mine near Coquimbo in Chili. It was first observed as a distinct species at Pary's Mine in Anglesey, whence the name Anglesite.

Anguilliform (Lat. *anguilla*, an eel, form, shape). Eel-shaped fishes, or those belonging to the tribe of eels.

Anguis. The name of a genus of Saurian reptiles, characterised by having subcaudal and abdominal imbricated scales, which scales consequently form a uniform covering over the whole body. The genus is now subdivided into the subgenera *Pseudopus*, *Ophisaurus*, *Acontias*, and *Anguis*, properly so called; the reptiles comprehended under the latter denomination have the tympanum concealed beneath the skin; the maxillary teeth compressed and hooked, and no teeth on the palate. The *Anguis fragilis*, blind, or slow worm, is a well-known example of this genus.

Angular Motion. The angular motion of a point or body is the same as that of the line, or radius vector, joining the moving point to some fixed one. The *angular velocity* of the body, as referred to the fixed point, is the ratio of the angle described by the radius vector, to the time occupied by its description.

Angular Section. The division of an angle into any number of equal parts. The general division of an angle into any proposed number of equal parts is a problem which mathematicians have not yet been able to solve. In modern mathematics the term angular sections denotes that branch in which the properties of circular functions are investigated.

Angustura Bark. The bark of the *Cusparia febrifuga*, originally imported from Angustura in South America; it is occasionally

ANHARMONIC RATIO

used in medicine as a tonic. A poisonous bark is occasionally found in commerce under the name of spurious Angustura, which appears to be the produce of a species of strychnos.

Anharmonic Ratio. A term of modern geometry, introduced by Chasles (*Aperçu Historique*), and applied to four points on a right line, as well as to four lines through a point (a plane pencil of four rays), or to four planes through a line (pencil of four planes).

The anharmonic ratio of four points, $abcd$, in a line is represented by the symbol $(abcd)$, which denotes the ratio of the ratios $\frac{ac}{cb}$

and $\frac{ad}{db}$; that is, $(abcd) = \frac{ac}{cb} : \frac{ad}{db}$. The seg-

ments here introduced are to be understood as positive or negative, according to the order in which the letters denoting them are written; thus, $ab = -ba$. Two anharmonic ratios are said to be *reciprocal* when their product, and *complemental* when their sum, is equal to unity. Now the twenty-four anharmonic ratios to which four points give rise, by changing their order in all possible ways, may be divided into six groups each consisting of four equal ratios, and such that the ratios in three groups are respectively the reciprocals of the ratios in the other three. In other words, each of the twenty-four ratios, or its reciprocal, is equal to one or other of the three *fundamental ratios* $(abcd)$, $(acdb)$, $(adbc)$. These, again, are expressible in terms of the first; in fact, the second is the reciprocal of its complement, and the third the complement of its reciprocal; so that, putting the first ratio, $(abcd) = a$, the second ratio $(acdb) = \frac{1}{1-a}$, and

the third ratio $(adbc) = 1 - \frac{1}{a} = \frac{a-1}{a}$.

The *anharmonic ratio of four lines*, $ABCD$, passing through the same point (of a pencil of four rays), is represented by the symbol $\sin. (ABCD)$, which is itself defined by the equation $\sin. (ABCD) = \frac{\sin. AC}{\sin. CB} : \frac{\sin. AD}{\sin. DB}$; it being understood that AC and CA represent angles between the lines A and C which, though equal in magnitude, are opposite in sign. If $abcd$ be the points in which any transversal is cut by the rays $ABCD$, it can be easily shown that $(abcd) = \sin. (ABCD)$. The whole modern system of geometry may be said to be founded on this equation, which expresses the *projective character of anharmonic ratios*. We learn from it, on the one hand, that the projections upon any line of any four points *in lineo* have the same anharmonic ratio as the latter; and, on the other hand, that all pencils whose rays pass through the same four points *in lineo* have the same anharmonic ratio.

The *anharmonic ratio*, $\sin. (ABCD)$, of a pencil of four planes passing through the same line or axis, is identical with that of the four lines in which the system is cut by a plane perpendicular to the axis, and is equal to that of the four points in which the pencil is cut by any

ANILOCYANIC ACID

transversal whatever, or, again, to that of the four lines in which the system is intersected by any plane whatever.

The *anharmonic ratio of four points on a conic* is identical with that of the lines joining the same to any other point of the curve; it being a property of conics that all pencils whose centres are on the curve, and whose rays pass through the four fixed points of the same, have the same anharmonic ratio. Similarly, the *anharmonic ratio of four tangents to a conic* is the invariable anharmonic ratio of the points in which these four tangents intersect any fifth.

Anhelation (Lat.). Difficulty of breathing.

Anhydrides. Bodies without water. A chemical term restricted to the anhydrous acids, or acids without water.

Anhydrite. Anhydrous sulphate of lime. It is harder and heavier than gypsum, into which it becomes slowly converted by the absorption of water.

Anhydrous (Gr. *ἀνυδρος*, from *ἀ*, priv., and *ὕδωρ*, water). Without water. A term often applied to salts, and to acids when deprived of water.

Anicut. An artificial dam, made in the course of a stream for the purpose of regulating the flow of a system of irrigation; under these circumstances the great anicuts which are established on the Indian rivers are always provided with bottom sluices, through which the water is let out for the regular supply. The term 'anicut' is of Indian origin, and is only used in technical works upon the irrigation of that country.

One of the plants yielding indigo. **ANIL** (Sansk. *nili*, *indigo*). A kind of indigo said to be a native of America, although now cultivated in the East Indies. It is very like *Indigofera tinctoria*, the true indigo, from which it chiefly differs in having compressed legumes, which are not torulose.

Aniles. Aniline, in which two atoms of hydrogen are replaced by one of a diatomic acid radical.

Anilic Acid. *Indigotic acid*, *Nitrosalicylic acid*. A solid, fusible, white crystalline body resulting from the action of nitric acid on indigo.

Anilides. Aniline, in which one atom of hydrogen is replaced by an electro-negative radical.

Aniline (from anil, the indigo plant). A colourless oil-like liquid of a strong odour and hot aromatic flavour, remarkable for its tendency to form crystallizable compounds with acids, so that it was originally termed *crystalline*. It is a product of the distillation of certain organic substances, and among others it has been derived from *indigo*. It is largely consumed in the preparation of mauve and magenta dyes, and for this purpose is derived from benzole, one of the constituents of coal tar. The formula of aniline is C_6H_5N .

Anilocyanic Acid. Cyanic acid in which hydrogen is replaced by phenyl.

Anilotic Acid. A product of the action of nitric acid upon salicin.

Animal Mundi (Lat. *soul of the world*). An expression formerly used to denote an ethereal essence or spirit, supposed to be diffused throughout the world, organising and actuating the whole and the different parts.

Animal (Lat.). The name of the higher division or kingdom of organised beings, distinguished by endowments of sensation and voluntary motion, superadded to the organic functions which animals possess in common with plants.

It has been objected to this definition, that the so-called sensitive plant is susceptible of impressions which cause action and motion of its parts, and that the embryos of *Algae* and *Conferva* have locomotion, while many of the lower animals are fixed as immovably to the earth as plants. But these objections have no real value, and could only have arisen from confounding irritability with sensation, which are two very different phenomena. It is the property of all living organised beings, and essential to their existence as such, to be susceptible of the impressions of certain stimuli, which occasion a reaction of the part stimulated, and the main object of physiology is to determine the precise mode in which each organ of a plant or animal reacts when stimulated. But it is here only necessary to state, that the muscular fibre in animals reacts when stimulated by an angular puckering called contraction, and this property is termed irritability. It is independent of the nerves and of sensation, for a portion of muscle removed from an animal body manifests the same contraction when irritated, whether mechanically, galvanically, or chemically. In the living animal the most common stimulus of the muscular contraction is the operation of the nerves, excited by the will, and is commonly the consequence of an act of sensation; but this is by no means the only stimulus by which the irritable property of the muscle is or can be called into play. In plants, universally, there are also irritable parts, or parts which react when stimulated by producing motion of a part or the whole of the body. It is this property which occasions the motion of the cambium or sap; it is by the same endowment that growing plants incline to the light, and extend their roots to the most congenial soil; or entwine their tendrils around the bodies which serve as their support; or move the stamens in regular succession towards the female part or pistil (saxifrage), or incline the pistil successively to each stamen (lily). By a modification of the same irritable property some plants close their leaflets or flowers at sunset; while others, like the nocturnal animals, go to sleep, as it were, at the approach of day. By a higher degree of this irritability the leaflets of the fly-trap (*Dionaea*) approach each other, and inclose the insect which has alighted upon them; and the *Mimosa pudica* withdraws its leaves from the offending touch, while the *Diosmodium* exhibits during the day a constant alternate movement of the lesser folioles, ana-

logous to the quicker vibration of the cilia which beset the respiratory organs of many molluscous animals, and which is equally independent of the nerves and of the will. The conditions of all these vegetable motions, which essentially distinguish them from the voluntary movements of animals, are, that they never proceed from an internal impulse, but are invariably the consequences of external stimulus, and take place, as it were, mechanically, and in the self-same manner; while in animals the motions arise out of an internal determination from parts not moving to the moving powers. There is also an essential difference in the nature of the motion itself, even when we compare the simplest animal with the plant. If we touch the feeler of a polype, it recedes from the irritant by a true contraction of the part within itself; but in the case of the sensitive plant, there is nothing like this contraction of the part touched, but only an articular plication of a contiguous part, without the dimensions of the irritated leaf being altered. Experiment has also shown that the intumescent parts of the mimosa, in which the irritable property is concentrated, move the leaf by an extension of cells, and not by a contraction of fibres.

It is true that many of the lower aquatic animals are rooted to the bottom: and these are often aggregated, and grow in a branched or plant-like form, as the scyphularia and other corallines; but, although voluntary motion of the whole is impossible, yet it is sufficiently conspicuous in the different parts, and the vital endowments of the individual polypus manifest a multiplied animal enjoyment, not the condition of a vegetable. The simplest monad of infusions exhibits the voluntary characteristics of the animal, by varying its movements to avoid obstacles or seize its food, while the locomotive embryo of the *Conferva dilatata* proceeds blindly onwards in an unvarying course, till its irritability is exhausted, and excites no idea of animality in the mind of an observer who has had any experience in the observation of animalcules. Ehrenberg has asserted that he can distinguish a moving embryo of the *Algae* from a polygastric monad, as easily as a tree from a bird.

The nerves are the organs on which spontaneous motion and sensation depend, and they chiefly distinguish the animal from the vegetable. Hence the nervous system has been termed the essence of an animal. All the other systems of organs appear in their plan of arrangement to be subject to the modification of the nervous system; and it is upon this system, therefore, that, in the classification of animals, their primary division is founded. Recent and more accurate researches have proved the existence of nerves in many of the lower organised animals, where their presence had been denied; and as, in every species in which the nerves have been detected, sensation has been found to depend exclusively upon them, we are hence led to assume that all animals in which sensation is observable, must

ANIMAL

have it depending on nervous matter present in some condition or other in their tissue; even where, as in the freshwater polype, this is apparently homogeneous, and where, from the extreme divisibility of the individual without loss of vitality in the detached parts, we may reasonably conclude the nervous molecules to be dispersed throughout the corporeal mass.

The attributes of sensation and voluntary motion modify, as might be expected, all the other functions which animals possess in common with plants. For example, as regards nutrition, vegetables which are fixed to the soil absorb immediately by their root the nutritive parts of the surrounding fluid. These roots are indefinitely subdivided; they penetrate the smallest interspaces, and seek, as it were, at a distance the nourishment of the plant to which they belong. Their action is tranquil, but unintermitting; being only interrupted when dryness has deprived them of the juices which are necessary for them.

Animals, on the contrary, which are rarely stationary, but which have the power of moving not only parts of the body, but the entire body, from place to place, require the means of transporting the provision necessary for their subsistence; accordingly, they have received an internal cavity, appropriated for the reception of the nutriment, and upon the parietes of which open the pores of the absorbent vessels, which have been justly compared to internal roots.

An internal cavity is requisite for animals on another ground;—their food must first be digested. Plants are supported by water containing carbonic acid, or the already dissolved organised material of the soil. But nutrition in animals does not immediately commence by the absorption of such fluids as the soil or the atmosphere furnishes, but their food consists of substances already in organic combination, which must be prepared and submitted to instruments for dividing and comminuting it, and to the action of solvent fluids. Thus digestion, or the preparatory assimilation of the food, is entirely peculiar to animals. They alone are endowed with organs of sensation, which guide them in the choice of aliment. They alone possess labial and other prehensile organs for seizing the food; teeth and jaws for comminuting and destroying its vitality if living; muscular actions, by which it is swallowed; and a reservoir for its reception endowed with chemical and vital powers for dissolving and assimilating such parts as are proper for nourishment, and which are selected and taken into the system through the purely vital sensibilities of the absorbent internal surface, while such parts as are unfit for nourishment are expelled.

A still more important difference, in connection with the digestive functions, arises out of the limitation of the powers of assimilation in the animal kingdom. Animals can convert into their own substance only matter which has already been organised; while plants have the power of assimilating the inorganic binary

compounds, carbonic acid and water. This property of plants is more important than perhaps at first sight might be suspected; for in the vital operations of animals a great quantity of organised matter is constantly decomposed, and is rendered, at all events, useless as nutriment for other animals; while, by means of combustion and other decomposing processes, an incalculable quantity of vegetable matter is continually resolved into binary compounds, or the ultimate elements of matter: hence, if the power of producing new ternary organised compounds out of carbonic acid and water had not been given to plants, both these and animals must, in process of time, inevitably have been annihilated, and successive creations of animals and vegetables would have been indispensable to maintain the present system of things. It is a beautiful instance of the harmony which pervades the relations of nature, that animals contribute as essentially to the support of vegetables, by a process of excretion, as these to the maintenance of animal life, by their powers of assimilation. The product of the respiratory interchange which takes place between the circulating fluids and the atmosphere in animals, is carbonic acid, which is an essential aliment of plants, and which plants, when in health and exposed to the influence of the sun's rays, absorb from the atmosphere by their respiratory organs, the leaves exhaling the superfluous oxygen which is extricated in their assimilative processes. Thus the constitution of the atmosphere is maintained by the different products which are evolved in the respiratory processes of plants and animals.

The circulation of the nutrient juices is much more independent of the external influences of light and heat in animals than in plants; and in most classes of the animal kingdom, the motion of the blood is principally determined by the contraction of an express muscular organ called the heart.

From a general review, therefore, of the nature and properties of living animals, their distinguishing characteristics may be summed up as follows:—

Animals are the only beings in nature which manifest sensation and spontaneous movements. They digest organised substances alone, and are always provided with a mouth, and an internal digestive cavity or canal.

Their nutrient fluids are received by an absorbent internal surface; while in plants they are taken up by an absorbent external surface.

Animals at all times, in respiration, exhale carbonic acid and absorb oxygen.

The tissues developed by animals comprise, as proximate principles, the quaternary compounds of carbon, hydrogen, oxygen, and nitrogen.

The two divisions of organisms called 'plants' and 'animals' are specialised members of the great natural group of living things; and there are numerous beings, mostly of minute size and retaining the form of nucleated cells, which manifest the common organic characters, but

without the distinctive superadditions of true plants and animals. Such organisms are termed 'Acrita' or 'Protozoa,' and include the *Amorphozoa* or Sponges, the *Rhizopoda* or foraminifers, the *Polycystinea*, the *Diatomacea*, the *Desmidiæ*, *Gregarina*, and most of the *Polygastria* of Ehrenberg, or infusorial animalcules of older authors. [ACRITA, PROTOZOA, and ZOOLOGY.]

Animal Substances. The principal products of the animal kingdom are chemically characterised by the presence of nitrogen as one of their ultimate elements, which is generally in combination with carbon, hydrogen, and oxygen. When, therefore, they are subjected to destructive distillation, ammonia is a common product; it is also often evolved when they are triturated with caustic potash, or quicklime.

Animalcules. [ACRITA, INFUSORES, and PROTOZOA.]

Animo. A resin which exudes from the *Hymenæa Courbaril*. It is brought from South America. It was formerly used in medicine, but is inert.

Animé. In Heraldry, when the eyes of any rapacious animal are borne of a different tincture from the creature itself.

Anions (a word formed from Gr. *ἀνά*, upwards, and *ίών*, a participle of the verb *εἶμι*, to go). Substances which in electro-chemical decompositions are evolved from their combinations at the surface by which the electricity is supposed to enter the electrolyte. [ELECTRODE.]

Anisamic Acid. White crystals derived from nitranisic acid, by the action of sulphide of ammonium.

Anisamide. Ammonia in which an atom of hydrogen is replaced by one of the negative radical anisyl.

Anisanilide. Anisamide in which an atom of hydrogen is replaced by phenyl.

Anise (Arab. *anisun*; Gr. *άνισον* = *άνισον*). The aromatic fruit of an eastern annual umbelliferous plant called *Pimpinella anisum*. It is principally employed in the manufacture of liqueurs, and against flatulence. *Star-anise* is the produce of *Illicium anisatum*, a tree belonging to *Winteraceæ*.

Anisette. A French liqueur, made by distilling anise, fennel, and coriander seed with brandy, and sweetening the product.

Anishydramide. A crystalline solid, product of the action of ammonia on hydride of anisyl.

Anisic Acid. Crystals formed on treating oil of anised with nitric acid.

Anisic Ether. A compound of anisic acid and ether.

Anisobryous (Gr. *άνισος*, unequal, and *βρύω*, I grow). A name given by some writers

including those insessorial species the toes of which are of unequal length, as in the nuthatch.

The term has been also applied to the odd-toed section of Ungulate Mammalia, in which the toes are of unequal number. [PERISSODACTYLA.]

Anisodynamous (Gr. *άνισος*, unequal, and *δύναμις*, power). A name given to Monocotyledonous plants, for the same reason as Anisobryous [which see].

Anisoin. A resinous body, formed by the action of oil of vitriol on oil of aniseed.

Anisostemonous (Gr. *άνισος*, unequal, and *στήμων*, a stamen). When the number of stamens in a flower neither corresponds with the calyx nor corolla in number or power; as, for instance, when a flower having five sepals has three or seven stamens, in which case the stamens are equal neither to the number of sepals nor any power of their number.

Anisotomidæ (Gr. *άνισος*, unequal, and *τέμνω*, I cut). A family of Coleopterous insects, having moniliform, or beaded, antennæ, subelongate, slender at the base, gradually increasing towards the apex, with a terminal club-shaped multiarticulate joint; palpi various, generally filiform; head small and ovate; body convex, never linear. This family includes eight genera: *Tritoma*, of which we have one indigenous species, *Tr. bipustulatum*; *Phalacrus*, of which Stephens describes twenty-eight British species, remarkable for their brilliant colours, and faculty of rolling up the body into a ball; *Ephistemus*, of which only three species are known, which have been detected in the neighbourhood of London; *Leiodes*, abundant in species, of which twenty-six are British; *Agathidium*, of which we have twelve species, inhabiting putrid wood and fungi, also found near London; *Clambus*, of which various species, all extremely minute, are known; *Clypeaster*, a term already appropriated to a genus of *Echinidæ*; lastly, *Sericoderus*; distinguishable from the rest of the family by its truncate elytra.

Anisyl. The hypothetical radical of aniseic acid and its derivatives.

Anker. A measure of wine or spirits equal to 10 of the old gallons, or $8\frac{1}{2}$ imperial gallons, = 2310·6 cubic inches.

Ankerite. A crystallized variety of Dolomite containing a large proportion of iron, found near Torness in the Orkneys, in amygdaloid. It is much prized as an ore of iron for smelting, and as a flux.

Annabergite. A hydrated arseniate of nickel, occurring in apple-green capillary crystals at Annaberg.

Annals. A chronological history: derived from the Roman *Annales Pontificum* or *Annales Maximæ*, which were annual records of passing events connected with religious observances kept by the Pontifex Maximus.

They seem, notwithstanding, materially from history, as the latter is now understood. Annals should comprise a succinct account of the events having reference to some

ANNATES

peculiar subject, as they occur in successive years. Inquiries as to the remote causes and consequences of events seem to be misplaced in them; though they are the essence of history. Cicero, when speaking of annalists, says, '*Unam dicendi laudem putant esse brevitatem, non exornatores rerum, sed tantum narratores.*' Annals are, in fact, rather materials for history than history. In the one, events only are narrated, in the other they are narrated and reasoned upon.

Annates or First Fruits. A fine paid to the king, as head of the church, by one promoted to an ecclesiastical benefice, and supposed to amount to one year's value of that benefice. This, however, is evaded by assuming as the basis of the valuation that made in 1635, and contained in what is termed the *Liber Regis*. In England, first-fruits go to the augmentation of Queen Anne's bounty.

Anne (St.) Order of. An order of knighthood, originally established in Holstein, and carried with the princes of that country into Russia. It was made a Russian order in 1796, and is now widely diffused.

Annealing (A. S. *anelan, to heat*). There are many substances which, when rapidly cooled, after having been heated, become exceedingly brittle,—an inconvenience often prevented by very slow cooling. This is especially the case with glass, which is therefore suffered to cool very gradually in an oven constructed for the purpose, and the process is called annealing. Many of the metals which have become harsh and hard in the process of manufacture, are softened in the same way; thus the blank pieces for coinage, several metallic wires, &c. are annealed.

Annihilator, Fire. An instrument in which a large quantity of non-combustible gas, chiefly carbonic acid, can be quickly generated. Directed on burning matters, this gas stops combustion by excluding air.

Anniversary (Lat. *anniversarius*). In Ecclesiastical usage, the day of the year on which an office is celebrated in honour of a deceased person. Hence, the annual return of any remarkable day. The services for 'anniversary days' of political significance, in the Church of England (Jan. 30. May 29. Nov. 5. Oct. 23) were abolished by Act of Parliament in 1859.

Annivite. An impure variety of Grey Copper, found in the valley of Anniviers, in Switzerland, with Copper Pyrites.

Annona (Lat.) In Roman writers, means, in a general sense, the year's increase, or the fruits of the year; and it also means the contribution or tax payable in corn, imposed on some of the more fertile provinces of the empire, as Sicily, Egypt, &c., for the use of the army and of the capital. The office of *Prefectus Annonæ* was of great importance at Rome, and continued down to the latest times of the empire.

Annotta, Annotto. Is the pulp of the seeds of the *Bixa Ordlana*, an Exogenous tree common in Cayenne and other parts of Ame-

ANNUITY

rica; it is made into a pulp, which, after having fermented, is rolled into pieces of two or three pounds' weight: it is imported under the names annotto, Roucou, or Orleans, and is used occasionally as an orange dye and for colouring cheese. It imparts little colour to water, but dissolves in alcohol and in alkaline solutions; its colour is not materially altered by acids or alkalis.

Annuaire. A name given by the French to publications on continuous or similar subjects, which appear in yearly parts or numbers. Of the existing *Annales*, that published by the *Bureau des Longitudes* is the most celebrated. There are also an *Annuaire Historique*, corresponding to our *Annual Register*, an *Annuaire de l'Etat Militaire*, an *Annuaire du Clergé de France*, &c.

Annual (Lat. *annualis*, from *annus, a year*).

A plant which arrives at perfection, passing from a seed into a perfect plant, yielding its fruit, and perishing, within the space of a year. The term also applies to cases where duration is for one growing season only. Many plants have perennial roots and annual stems, that is, stems perishing and being renewed annually: such plants are usually denominated *Herbaceous*, in contradistinction of shrubs and trees, which have more durable stems.

Annuity. A rent or sum receivable yearly for a term of years.

An annuity may be receivable during a definite number of years, or during a period of uncertain length; for example, during the life of one or more individuals. In the former case it is called an *Annuity Certain*; in the latter, a *Contingent Annuity*.

An annuity which is not to be entered upon immediately, but after a certain number of years, is called a *Deferred Annuity*; if it is not to be entered upon till after the death of some person or persons now living, it is called a *Reversionary Annuity*. When limited by the duration of a given life or lives, it is called a *Life Annuity*; and when it is to continue only for a term of years, provided an individual or individuals now living shall survive that term, it is called a *Temporary Life Annuity*.

The practice of raising or investing money on annuities is attended with many advantages in the ordinary affairs of the world. A merchant or trader thus finds the means of clearing off his engagements gradually by the profits of his trade, and without losing possession of the capital necessary for carrying on his speculations; and one who possesses unemployed capital is thus enabled to convert it into an equivalent annual income for life, and thereby derive the utmost benefit from it while he lives, without risk of destitution from its failure. The accurate determination of the value of annuities in present money is therefore a subject of very considerable importance. We propose to explain the principles on which the calculation is made, and to apply them to a few of the cases of most frequent occurrence.

Annuities Certain.—The values of annuities

ANNUITY

of this kind depend only on the rate of interest of money, and the number of years during which they are payable, and are easily calculated. Suppose it were required to determine the value, in present money, of an annuity of 100*l.* per annum, to continue five years, or till five payments have been made, the interest of money being 5 per cent., we should reason as follows:—The first payment of 100*l.* becomes due at the end of a year from the present time; but since 100*l.* in hand is equal to 105*l.* receivable at the end of a year, the present value of the first annual payment is 100*l.* reduced in the proportion of 100 : 105, or of 1 to 1·05; that is, it is equal to $\frac{100}{1\cdot05}$ *l.* In like manner, the present value of 100*l.*, to be received at the end of two years, is less than if it were receivable at the end of one year, in the proportion of $\frac{1}{1\cdot05}$; consequently, the present value of 100*l.*, to be received at the end of two years, is $\frac{100}{(1\cdot05)^2}$ *l.* Pursuing the same reasoning, the present value of 100*l.*, to be received at the end of three years, is $\frac{100}{(1\cdot05)^3}$ *l.*; at the end

of four years it is $\frac{100}{(1\cdot05)^4}$ *l.*; and so on till the end of the term. But it is evident that the present value of the whole annuity is the sum of the values of all the annual payments; hence the required value of the proposed annuity is—

$$\frac{100}{1\cdot05} + \frac{100}{(1\cdot05)^2} + \frac{100}{(1\cdot05)^3} + \frac{100}{(1\cdot05)^4} + \frac{100}{(1\cdot05)^5}$$

This reasoning may be easily generalised. Let *a* denote the annual payment, *r* the rate of interest, *n* the number of years during which it continues, and *s* the present value of all the payments, we shall then have—

$$s = \frac{a}{1+r} + \frac{a}{(1+r)^2} + \frac{a}{(1+r)^3} + \dots + \frac{a}{(1+r)^n}$$

For the sake of abridging, put $v = \frac{1}{1+r}$, and the formula will become—

$$s = a(v + v^2 + v^3 + \dots + v^n)$$

$$\text{or } s = av(1 + v + v^2 + v^3 + \dots + v^{n-1})$$

The sum of the series within the parenthesis is $\frac{1}{1-v}(1-v^n)$; therefore, $s = \frac{av}{1-v}(1-v^n)$; or, writing $\frac{1}{r}$ for $\frac{v}{1-v}$, $s = \frac{a}{r}(1-v^n)$.

From this it is easy to understand the method of proceeding in all other cases of annuities certain. For instance, let it be required to find the present value of an annuity deferred for three years, that is, not to be entered upon till after the end of three years; and to continue ten years from that time. It is evident that we have only to find the value of an annuity of the same amount for thirteen years, and also for three years, and to subtract the latter value from the former. The difference is the value of the deferred annuity. Again, suppose that the annuity, instead of being payable yearly, is

to be paid half yearly, or quarterly. It is obvious that an annuity of 100*l.* per annum for ten years, to be paid in half-yearly payments, the interest of money being 5 per cent., is the same thing as an annuity of 50*l.* per annum for twenty years, payable yearly, interest being 2½ per cent.; or an annuity of 25*l.* per annum, payable yearly for forty years, interest being 1½ per cent. The principle of the calculation is the same in all the cases.

Life Annuities.—When the annuity is to cease with the life of an individual, or any number of individuals, the calculation of its value is a little more complicated, as it becomes necessary not only to find the present value of the payment to be made at the end of any given year, but also to take into account the probability of its being received, that is to say, the probability that the individual or individuals, on the duration of whose lives it depends, will be alive at that period. Let the annuity depend on the continuance of a single life, and let us denote the probability that the life will be in existence at the end of

1,	2,	3,	4,	5, &c. years,
by p_1 ,	p_2 ,	p_3 ,	p_4 ,	p_5 , &c.;

and, as before, let $v = \frac{1}{1+r}$. The present value

of 1*l.*, to be received certainly at the end of a year, is *v*; but the probability of receiving it is p_1 ; therefore the value of 1*l.* at the end of the year, subject to the chance of the given life being then in existence, is p_1v . In like manner, the value of 1*l.*, to be received certainly at the end of two years, is v^2 ; and the chance of its being received is p_2 ; therefore, the value subject to the contingency is p_2v^2 , and so on.—Let *A* denote the value of 1*l.* to be received yearly during the whole continuance of the given life, we have evidently

$$A = p_1v + p_2v^2 + p_3v^3 + p_4v^4 + \&c.$$

continued till *p* becomes nothing, or till the extinction of human life.

It is now necessary to consider the nature of the quantities represented by p_1, p_2, p_3 , &c., and to show in what manner they are to be computed. By the doctrine of chances, the probability of the occurrence of any event is measured by the quotient that arises from dividing the number of chances favourable to its occurrence by the whole number of ways in which it can happen. Consequently, if *n* denote the number of individuals living at a given age, *n*₁ the number of the same individuals alive at the end of one year, *n*₂ the number living at the end of two years, *n*₃ the number living at the end of three years, and so on, we shall have $p_1 = \frac{n_1}{n}, p_2 = \frac{n_2}{n}, p_3 = \frac{n_3}{n}, p_4 = \frac{n_4}{n}$, and so on. The numbers *n, n*₁, *n*₂, &c., are taken from a table of mortality, or a table constructed to show the ratio of the number of individuals who enter upon every given year of life to the number who survive that year, or who die in the course of it.

There is no other method of finding the

ANNUITY

value of the series represented by Δ than that of calculating the value of its different terms separately, and adding the whole into one sum. Nevertheless, as the object in general is not to determine merely the value of an annuity on life at a particular age, but to construct a table showing its value for all the different ages of life, there is a method of deducing the value at one age from the value at another age, which greatly abridges the labour of calculation. Thus, suppose the age of the individual on whose life the annuity depends to be 40, and the probabilities of a life of 40 continuing 1, 2, 3, &c. years to be p_1, p_2, p_3 , &c., we have, by what is already shown,

$$\Delta = p_1v + p_2v^2 + p_3v^3 + \dots + p_nv^n.$$

Now, let Δ_1 be the annuity on a life of 41, that is, one year older than the former; and let the probabilities of a life of 41 living over 1, 2, 3, &c. years be q_1, q_2, q_3, q_4 , &c., we shall have

$$\Delta_1 = q_1v + q_2v^2 + q_3v^3 + \dots + q_nv^n.$$

But the quantities q_1, q_2, q_3 , &c., are not independent of p_1, p_2, p_3 , &c.; the one set are evidently functions of the other. In fact, the probability that a life of 40 will live over 2 years is equal to the probability that a life of 40 will live over 1 year, multiplied into the probability that a life of 41 will live over 1 year. This is evident from the manner in which the probabilities are obtained; for n, n_1, n_2 , being the numbers respectively alive at the ages of 40, 41, and 42, the probability that

a life of 40 will live over 1 year is $\frac{n_1}{n}$, and

that it will continue 2 years, $\frac{n_2}{n} \times \frac{n_1}{n_1} \times \frac{n_1}{n}$. In

like manner, the probability of a life of 40 living over 3 years is equal to the probability of a life of 40 living over 1 year multiplied into the probability that a life of 41 will live over 2 years; and so on. Hence, $p_2 = p_1q_1$

or $q_1 = \frac{p_2}{p_1}, q_2 = \frac{p_3}{p_1}, q_3 = \frac{p_4}{p_1}$, and so on. We have, therefore,

$$\Delta_1 = \frac{1}{p_1} (p_2v + p_3v^2 + p_4v^3 + \dots + p_nv^{n-1});$$

and, multiplying both sides by p_1v ,

$$p_1v\Delta_1 = p_2v^2 + p_3v^3 + p_4v^4 + \dots + p_nv^n.$$

On subtracting this equation from

$$\Delta = p_1v + p_2v^2 + p_3v^3 + p_4v^4 + \dots + p_nv^n,$$

we get $\Delta - p_1v\Delta_1 = p_1v$, whence $\Delta = p_1v(1 + \Delta_1)$. This formula, which was found by the celebrated Euler, gives the following rule for determining the value of an annuity on a life at any age from the value of the same annuity on a life one year older, and renders the computation of the whole table not much more laborious than the direct calculation of the annuity on the youngest life. Add one to the value of an annuity on a life one year older; multiply the sum by the probability that the given life will live over one year, and also by the present value of 1*l.* to be received at the end of a year. The product is the value of the annuity on the given life.

The values of deferred and temporary

annuities on single lives are easily found from the table of the values for the whole of life. For example, let it be required to determine the present value of an annuity on the life of an individual now aged 40, but deferred 10 years, that is to say, not to commence till the expiration of 10 years. After the 10 years, if the individual be then alive, the value of the annuity on the remainder of his life is the annuity on a life of 50: let this be called Δ . The present value of 1*l.* payable at the end of 10 years is v^{10} ; and the probability of receiving it, in the event of an individual now aged 40 being then alive, is p_{10} ; therefore, the present value of Δ , subject to the contingency, is $p_{10}v^{10}\Delta$. In general, the value of an annuity deferred n years is $p_nv^n\Delta_n$ where Δ_n represents the annuity on a life n years older than that corresponding to Δ .

A temporary annuity on a single life for n years is found by adding together the first n terms of the series

$$p_1v + p_2v^2 + p_3v^3, \text{ \&c.}$$

But it is frequently more easy to find it by means of the deferred annuity on the same life for the same term of years; for it is obvious that the temporary annuity and deferred annuity are, together, equal to the whole annuity. Thus, let Δ be an annuity for the whole of life, Δ_n a temporary annuity of the same amount for n years on the same life, and Δ_{n+1} the same annuity deferred n years, we shall have $\Delta_{n+1} =$

$$\Delta - \Delta_n$$

Annuities on Joint Lives.—The method of calculating annuities, to be paid so long as two or more individuals shall continue to live together, is equally simple. Let the probabilities that Δ and Δ will live over

1,	2,	3,	4, &c. years
be $p_1,$	$p_2,$	$p_3,$	$p_4,$ &c.
$q_1,$	$q_2,$	$q_3,$	$q_4,$ &c.

respectively, then the probability that both will live over

$$1, \quad 2, \quad 3, \quad 4, \text{ \&c. years}$$

will be $p_1q_1, p_2q_2, p_3q_3, p_4q_4$, &c., and the value of an annuity on their joint lives which we may denote by Δ , becomes

$\Delta = p_1q_1v + p_2q_2v^2 + p_3q_3v^3 + p_4q_4v^4 + \text{ \&c.}$, continued till p or q becomes nothing, or to the last age in the table. When more lives than two are involved, the method of proceeding is obvious.

Another question of this kind frequently occurs, namely, to determine the value of an annuity on the survivor of two or more lives. Let us suppose two lives only are concerned; and let Δ be the value of the annuity on the first life, Δ that on the second, and Δ that on the joint lives (i. e. to be paid till one of the lives shall drop). Let p_x = the probability the first will live over x years, and q_x = the probability the second will live over x years. We shall then have

$1 - p_x$ = probability 1st will die before the end of x years,

$1 - q_x$ = prob. 2d will die before the end of x years,

ANNUITY

$(1-p_x)(1-q_x)$ = prob. both will die before the end of x years ;
and hence the probability that both will not die before the end of x years is $1 - (1-p_x)(1-q_x)$, which is equal to $p_x + q_x - p_x q_x$. This expression, therefore, is the measure of the probability that a payment will be received at the end of the x th year ; and supposing the annuity to be 1*l.*, the present value of that payment certain is v_x . Multiplying this into the above probability, we get the value in present money of the payment to be made at the x th year, if one or both of the lives survive, viz.

$$p_x v^x + q_x v^x - p_x q_x v^x.$$

Now, if we substitute successively the numbers 1, 2, 3, 4, &c. for x in this expression, we shall have the value of the 1st, 2d, 3d, 4th, &c. payment ; and the sum will be the value of the annuity to continue during the life of the survivor. But it has been shown that

$$p_1 v^1 + p_2 v^2 + p_3 v^3 + p_4 v^4 + \&c. = A,$$

$$q_1 v^1 + q_2 v^2 + q_3 v^3 + q_4 v^4 + \&c. = B,$$

$p_1 q_1 v^1 + p_2 q_2 v^2 + p_3 q_3 v^3 + p_4 q_4 v^4 + \&c. = C$; therefore the value of the annuity is $A + B - C$; that is to say, the value of an annuity on the survivor of two lives is equal to the sum of the annuities on each of the single lives diminished by the annuity on the joint lives. [For applications of the doctrine of annuities, see the terms ASSURANCE, SURVIVORSHIP.]

Annuity Tables.—In consequence of the numerous and important applications of the doctrine of life annuities to commercial purposes, great pains and labour have been bestowed in the formation of tables of their values at all the different ages of human life. These tables differ very considerably, not from any difference in the methods of constructing them, but from the difficulty of estimating with numerical precision the probable duration of human life. The first table of the kind which we possess was given by Dr. Halley, in a paper inserted in the *Philosophical Transactions* for 1693, and founded on observations of mortality made at Breslaw. De Moivre, in a tract entitled *Annuities on Lives*, published in 1724, gave a very elegant formula for determining the value of a life annuity at any age, founded on the hypothesis that the annual decrements of life are equal ; or that out of a given number of individuals, equal numbers die every year, till all become extinct. In 1742, Thomas Simpson published tables of annuities on single and joint lives, calculated from observations of mortality made in London. These were extended in a supplementary work published in 1752. Deparcieux, in 1746, published his excellent *Essai sur les Probabilités de la Durée de la Vie Humaine*, with tables of annuities on single lives, calculated from the probabilities deduced from the registers kept in different religious houses, and the lists of the nominees in the French Tontines. These tables were decidedly the best that had then appeared, and even now, when much more extensive observations have been obtained, are of great value. But the tables which acquired the

most extensive reputation were the celebrated Northampton Tables, calculated by Dr. Price from registers kept in the city of Northampton. These, till a late period at least, have formed the guide of the transactions of all the assurance offices. They give the probabilities of life, and consequently the value of the annuities, considerably lower than all other good observations have subsequently proved them to be ; but, in proportion as the annuities are too low, the premiums for assurance deduced from them are too high ; and hence they were extremely safe for the offices, though proportionally unjust for the assured. In consequence of the competition resulting from the recent great increase in the number of assurance offices, they now transact their business on more equitable terms. An extensive set of annuity tables was given by Mr. Milne in his *Treatise on the Valuation of Annuities and Assurances on Lives and Survivorships*, published in 1815. One of these tables, founded on observations made at Carlisle, has acquired considerable reputation, and perhaps gives a nearer representation of the value of life at present in England generally than any other which has yet been published. The

VALUE of a LIFE ANNUITY of 1*l.*, Interest being 4 per Cent.

annuities granted by government are now valued according to a table calculated by Mr. Finlaison from the mortality experienced among the different classes of annuitants. This table possesses a great advantage over most others, inasmuch as it is founded on observations of the actual numbers who entered upon and passed through the several years of age among a class of individuals none of which could be lost sight of, so that no uncertainty remains about the accuracy of the data. The values of the annuities are in general considerably higher than those given by the Northampton Table, at the same rate per cent., and approach to those of the Carlisle Table. The observations also indicate a considerable difference between the values of male and female life at the same ages; a fact which appears to be borne out by all the accurate registers of mortality which have been kept in this and other European countries. [MORTALITY.]

The preceding table, extracted from Mr. Finlaison's Report to the Lords Commissioners of the Treasury (March, 1829), shows the value of a life annuity of $l.$ at all the different ages of male and female life to 90, according to the mortality among the government annuitants, the rate of interest being 4 per cent.

ANNUITY. In Law, a sum of money paid yearly, and charged on the personal estate, or on the person, of the individual from whom it is due: thus differing from a rent-charge, which is charged on real estate. Annuities are commonly employed as a system of borrowing and lending; the borrower of the money being the grantor of the annuity, and the lender the grantee. An annuity is either for a term of years, for a life or lives, or in perpetuity; and the latter, although charged on personal property, may by the terms of the grant descend as real estate. A perpetual annuity is redeemable by the grantor, subject, however, to conditions in the grant, by which he may preclude himself from redeeming for a certain period of years. An annuity for life or years is only redeemable by consent of the parties, unless it has been rendered redeemable on specific conditions in the original grant. Annuities for life, on account of the risk to which the grantee is exposed, were not within the usury laws: they were, therefore, formerly commonly resorted to as a mode of raising money by loan at high interest. By the stat. 53 Geo. III. c. 141, a memorial of every instrument by which annuities for life are granted, must be enrolled in the Court of Chancery, containing the date, names of parties and witnesses, and conditions of contract, and the grantor may have the instrument cancelled, if the consideration money is not bona fide paid to him; but this Act was intended to relate only to annuities granted in return for loans, and was repealed in 1854. Since the repeal of the usury laws there has been no object in securing by way of annuity loans made to private persons, and this practice has consequently fallen into disuse. Loans contracted by sovereign states are, however, still frequently

so secured. Annuities created by will are general legacies, and subject to abatement, in proportion with other legacies, on a deficiency of the funds of the testator.

Annular Eclipse. An eclipse of the sun, in which the moon conceals the whole of the sun's disk, excepting a bright ring all round the border. [ECLIPSE.]

Annulate (Lat. *annulus, a ring*). Formed or divided into distinct rings, or marked with differently coloured annulations.

Annulet. Any small member which is inserted under the architectural decorations of a capital, without much reference to the character of the profile of the members themselves. Properly speaking, the term ought to be confined to the four or five fillets under the echinus of the Doric order; but by extension it is made to express the same mouldings upon capitals of every description, even of mediæval architecture. The columns in the Temple Church and in Salisbury Cathedral are said to be 'annuleted,' because connected by a species of clustered annulet.

Annulosa (Lat. *annulus, a ring*). A term used to designate, sometimes a part, sometimes the whole, of the articulate division of Invertebrate animals. [ARTICULATA.]

Annulus (Lat.). This word is used in Botany in several different senses. In the mushroom and some other fungi it is applied to a collar which surrounds the stipes just below the hymenium; in mosses it signifies a rim external with respect to the peristome; in ferns it is an elastic rib which girds the theca or spore-cases nearly all round, and which by its contraction tears them open and disperses the spores.

ANNULUS. In Geometry, denotes a solid formed by the rotation of a circle around a line in its own plane, but not cutting it. The area of the annular surface, as well as the volume of the annulus, may be found by the general rules applicable to surfaces of rotation. [QUADRATURE and CUBATURE.]

Annunciation, Feast of the. A festival of the Christian church, in commemoration of the announcement of the conception of our Saviour to the Blessed Virgin by the angel Gabriel.—St. Luke i. 26, 38. It is celebrated on March 25, commonly called Lady-day.

ANNUNCIATION, Order of the. Founded in Savoy by Amadeus VI., in 1335, as the order of the Collar: received its present name from Charles III. The reigning king of Sardinia (now Italy) is grand-master of the order.

Anobium. The name of a Fabrician genus of Coleopterous insects, characterised by antennæ filiform, the last joints larger; thorax nearly round, not margined, receiving the head; palpi clavate; labium entire.

Anode (Gr. *ἀνοδος, a way up*). The positive pole of a voltaic battery, or the way by which electricity is figured to the mind as entering substances through which it passes; opposed to cathode, the road or way by which it goes out.

ANODON

Anodon (Gr. $\alpha\acute{\nu}\delta\omicron\nu\varsigma$, a tooth). The name of a genus of Lamellibranchiate Bivalves, including the common freshwater mussel, the shell of which has no articular processes, or teeth, at the hinge. The name has also been applied to a genus of serpents, which have the teeth in the mouth very minute, or rudimental: the *Anodon typus* (*Coluber scaber* of Linnaeus), a South African species of this genus, lives upon the eggs of birds, which, by the structure of the mouth above-mentioned, it is enabled to swallow entire. The inferior spinous processes of the cervical vertebrae are prolonged into the gullet, and there receive a coating of enamel; thus serving the office of teeth, where the breaking of the egg may take place without the loss of any of its nutritious contents.

Anodyne (Gr. $\alpha\acute{\nu}\delta\omicron\nu\nu\varsigma$, from $\alpha\acute{\nu}$, neg. and $\delta\delta\iota\nu\alpha$, pain). A term applied in Physic to medicines which relieve pain. Anodynes are chiefly of vegetable origin, and generally come under the head of sedatives or narcotics.

Anolis. *Anoli*, *anoalli*, is the vernacular name, in the Antilles, of the lizard to which the generic term *Anolis* is applied. This term is restricted in Zoology to those iguanoid species of lizard which have minute scales on the under part of the last joints of the toes, while the next joints are extended into soft pads transversely striated, but not organised to act as a sucker, as in the geckos. All the species of *anolis* are natives of the warmer parts of the American continent; all are remarkable for their power of inflating the skin of the throat; they are light and agile in their movements, and in the beauty and brilliancy of their colour exceed all others of the Saurian order.

Anomalistic Year. The interval of time in which the earth completes a revolution with respect to any point in its elliptic orbit. The tropical year is measured by the return of the earth to the same equinox; the sidereal year by its return to the same fixed star; the anomalistic year by its return to the same apsis or extremity of the greater axis of its orbit. The major axis of the diameter of the earth's orbit is not fixed, but has a progressive motion eastward among the stars. Suppose that when the earth is at its perihelion, or point nearest the sun, the other extremity of the major axis points to a given star; when the earth, after having completed a revolution, returns to its perihelion, the diameter will point $11^{\circ}8'$ eastward of the same star; consequently the ano-

malistic year is longer than the tropical year, for the line of the equinoxes goes backwards at the rate of $50''$ in a year; therefore after the earth has completed a revolution with respect to the line of the equinoxes, it has still to describe $50''$ + $11^{\circ}8' = 81^{\circ}9'$, before it overtakes the same point of its ellipse. The time occupied in describing this arc is 25 minutes, and the length of the tropical year is

ANOMODONTIA

365 d. 5 h. 48 m. 45 s.; therefore the anomalistic year is 365 d. 6 h. 13 m. 45 sec.

Anomaly (Gr. $\alpha\nu\alpha\mu\alpha\lambda\iota\alpha$, unevenness). A term used in Astronomy to denote the angular distance of a planet from its perihelion, as seen from the sun. There are three different anomalies: the true, the mean, and the eccentric. Let ApB be the orbit of a planet, S the sun, AB the transverse diameter, and C the centre. Through p draw pQ perpendicular to AB , meeting the circle circumscribed about the orbit in z . On account of its unequal distances from the sun, the angular motion of a planet in its orbit is irregular; conceive, therefore, that while the real planet moves from A to p , another planet moving in the same orbit, with an equable motion, and performing a revolution in the same time, has moved from A to P . This being supposed, the angle ASP is the true anomaly; ASP is the mean anomaly; and ACz the eccentric anomaly. The mean anomaly is proportioned to the time of description; to find the true anomaly is a problem of considerable difficulty, requiring the aid of the higher mathematics. From the circumstance of its having been first proposed by Kepler, it is usually called Kepler's problem.

ANOMALY. In Grammar, an exception from a general rule.

Anomeans (Gr. $\alpha\nu\omicron\mu\omicron\iota\alpha\iota$). In Ecclesiastical History, the name given to that extreme party among the Arians who denied the similitude of the Son to the Father. (Milman, *History of Christianity*, book iii. ch. v.)

Anomia (Gr. $\alpha\acute{\nu}\omicron\mu\omicron\iota\alpha$, neg. $\nu\omicron\mu\omicron\varsigma$, law; because not easily reduced to the ordinary laws of classification). The name of a Linnæan genus of the *Vermes Testacea*, the characters of which, as given in the *Systema Nature*, apply to the organisation of the soft parts and shell of the modern *Terebratula*. Modern naturalists have limited the term to a genus of acephalous mollusks having two unequal irregular thin valves, of which the flatter one is deeply notched at the cardinal margin. The greatest part of the central muscle traverses this opening to be inserted into a third piece, which is sometimes calcareous, and sometimes simply horny, but which is always attached to foreign bodies. The rest of the muscle serves to join one valve to the other. The animal has a small vestige of a foot, and is remarkable for the length of its labial tentacles. They are attached to oysters and other shells, and frequently acquire the form of the surfaces with which their growing margins are in contact.

Anomodontia (Gr. $\alpha\nu\omicron\mu\omicron\iota\alpha$, without law, and $\delta\delta\iota\nu\alpha$, tooth). This order of reptiles, of which all the forms have become extinct, is characterised by having teeth wanting, or limited to a single maxillary pair, having the form or proportions of tusks; a foramen parietale; two nostrils; tympanic pedicle fixed; vertebrae biconcave; trunk ribs long and curved, the anterior ones with a bifurcate head; sacrum

ANONA

of more than two vertebræ; limbs ambulatory. It is composed of the *Dicynodontia* (*Dicynodon*, *Psychognathus*), and the *Cryptodontia* (*Oude-nodon*, *Rhynchosaurus*), and the *Cynodontia* (*Galesaurus*, *Cynochampsa*).

Anona (Menona, the Malayan name of the *custard apple*). A genus of Exogenous trees, representative of the *Anonaceæ*, found in hot latitudes, with large roundish pulpy fruit, which in some species is used as food. The custard apple, so named from its seeds lying in a whitish sweet cream-like pulp, is produced by *A. squamosa*; the cherimoyer, the most esteemed of all the fruits in Peru, is yielded by *A. Cherimolia*; and other kinds are known.

Anonaceæ. [ANONA.] An extensive natural order of Exogenous plants, comprehending evergreen trees or shrubs, whose fruit is sometimes eatable, as in *Anona*, most generally dry and aromatic, as in the genera *Unona*, *Habselia*, &c., whose ripe carpels furnished the *Piper ethiopicum* of the old drug shops. The great mark of *Anonaceæ* is their having ternary (trimerous) polypetalous flowers, and a ruminate albumen.

Anonymous (Gr. ἀνώνυμος, *nameless*, from ἀ, priv., and ὄνομα, *a name*). In Literature, works published without the name of the author. Those published under a false name are termed *Pseudonymous* (ψευδής, *false*). The best catalogue of anonymous works is that of Barbier (*Dictionnaire des Ouvrages Anonymes et Pseudonymes*, 3 vols. Paris 1822-1824, and now in course of republication); but it is confined solely to French works. There is nothing of the kind in English literature.

Anoplotherium (Gr. ἀνοπλος, *unarmed*, and θηρίον, *beast*). An extinct genus of even-toed Artiodactyle Pachydermata, from the Upper Eocene, characterised by the shortness and feeble size of the canine teeth, which resemble the incisors, and are consequently unfitted for being used as weapons of offence. As the canines in this genus do not project beyond the level of the incisors and molar teeth, no vacant interspace, or *diastema*, is required in the dental series of the opposite jaw for the reception of their pointed extremities, and consequently the series of teeth is uninterrupted in both jaws, a structure observable in no existing animal save man. The *Anoplotherium* has $\frac{6}{6}$ incisors,

$\frac{1-1}{1-1}$ canines, $\frac{4-4}{4-4}$ premolars, and $\frac{3-3}{3-3}$ molars in each jaw. The *Anoplotherium commune* (Cuv.) is about the size of a wild boar, but longer in the body, with the head of an oblong form, and a tail of considerable thickness and as long as the body. Its probable use was to assist the animal in swimming. Another species (*Anoplotherium medium*) is of a size and form more nearly approaching to the light and graceful character of the gazelle. A third species was about the size of a hare. All the species, from the form of the teeth and the absence of claws or horns, appear to have been singularly deficient in defensive organs.

ANTACIDS

Anorexy (Gr. ἀνορεξία, from ἀ, neg. and ορεξίς, *appetite*). Loss of appetite.

Anorthite (Gr. ἀ, neg., ὁρθός, *straight*). A lime-Felspar, with the same composition as Scapolite, except that small portions of the lime are replaced by magnesia, potash, and soda. It occurs in white, translucent or transparent crystals, with a vitreous lustre inclining to pearly on the planes of cleavage, principally at Vesuvius, amongst the older lavas of Monte Somma, generally occupying the cavities of chloritic masses. It is also found in Ireland in greenstone-dykes traversing the limestone of Carlingford Mountain, co. Down.

Anorthoscope (Gr. ἀ, neg., ὁρθός, and σκοπέω, *I view*). The name given by M. Plateau, of Brussels, to an instrument invented by him, and intended to produce a peculiar kind of anamorphoses by means of two discs rotating rapidly one before the other, the hind one of which is transparent, and bears distorted figures, while the front one is opaque, and pierced with a small number of narrow slits. On revolving the disc the distortions appear as amusing and interesting figures and pictures. As in other toys of a similar kind, the *Phenakistoscope*, for example, the effect depends on the persistence of impressions on the retina.

Anosmia (Gr. ἀ, without, and ὀσμή, *smell*). Loss of the sense of smelling.

Anostoma (Gr. ἀνω, *upwards*, and στόμα, *mouth*). A genus of pulmonate or air-breathing Gasteropods, allied to *Helix*, in which the aperture in the adult is turned upwards towards the spire of the shell, and ingent.

Anourans (Gr. ἀ, priv., and οὐρά, *tail*). A name applied to a tribe of Batrachian reptiles, which lose the tail in arriving at maturity; as the toad and frog.

Anse de Panier. A French phrase applied to arches which are the result of elliptical curves in section; they are the most elegant form of arch used in bridge building.

Anseres (Lat.). In the Linnæan arrangement, the name of the third order of birds, having the bill broad at the top, and covered with a soft skin; the feet webbed. [NATATORES.]

Ant. [FORMICA.]

Ant-eaters. [MYRMECOPHAGA.]

Anta. A term used to express the species of pilaster, or pillar, used by the Greeks to terminate the side walls of the temples, such as the temples of Agrigentum, Eleusis, and Rhannus; they differ from pilasters in this respect, that they are not repeated in the length of an elevation, whereas the pilasters may be repeated as often as the architect desires. The capital of an anta differs also from that of a pilaster, inasmuch as the former is a special composition, whilst the latter is but a reproduction, on the flat, of the decorations of the columns themselves. The return faces of the anta are generally much narrower than the face next the corresponding column; but there is no absolute rule upon this subject.

Antacids. Medicines which neutralise the acid of the stomach.

ANTAGONISTICS

Antagonistics (Gr. ἀνταγωνιστής). In Anatomy, those muscles are so termed which are opposed to others in their action, as the extensors to the flexors, the pronators to the supinators, the abductors to the adductors, &c.

Antalgic (Gr. ἀντί, *against*, and ἄλγος, *pain*). That which relieves pain.

Antanaclosis (Gr.). In Rhetoric and Composition, a figure in which a word is repeated, but in a different sense or different inflection from the first; which gives a kind of antithetical force to the expression

Labitur, et labetur in omne volubilis ævum.

The return to the former series of thought and diction after the interruption of a parenthesis, is also termed Antanaclosis.

Antaphrodisiacs (Gr. ἀντί, and Ἀφροδίτη, *Venus*). Medicines which quell amorous desires.

Antarctic (Gr. ἀνταρκτικός). Opposite to Arctic. Antarctic circle, one of the small circles of the sphere, parallel to the equator, and distant $23^{\circ} 27\frac{1}{2}'$ from the South pole. Antarctic pole, the South pole, or southern extremity of the axis of the earth. [ARCTIC.]

Antarctic Current. This drift current commences on the shores of Victoria land, in the perpetual frost of the south pole. It carries vast quantities of ice and cold water towards the north-east and east, and becomes converted into a coast current, washing and cooling the shores of South America, performing therefore a work nearly the converse of that performed by the Gulf Stream on the shores of Europe. It conveys drift ice to the latitude of about 66° .

Besides the part that is converted into the Peruvian coast current, and runs north, another portion flows more to the south after reaching the coast of Chili, between Concepcion and Valparaiso, reaching Cape Horn (or Horn), and passing into the Cape Horn current.

The temperature of the land is so greatly affected by this current that the general mean temperatures of air and ocean in latitude 12° south are reduced the one by 11° and the other by 14° .

Antarctic Ocean. The part of the great ocean within the Antarctic circle is estimated to contain about two millions of square miles, and might with propriety be considered as part of the Pacific Ocean. The land lying within the Antarctic circle is probably of far greater extent and much more elevated than that of the Arctic; but the coast can rarely be approached, the ice being more continuous, and advancing for the most part into much lower latitudes. The climate throughout is excessively severe.

Antecedent. In Analysis, the name given to the first of the two terms composing a ratio. Thus in the ratio $a : b$, a is the antecedent, and b is denominated the consequent.

ANTECEDENT. In Logic, the first member of an hypothetical proposition; followed by the consequent; as in the following instance:—

If we live (*antecedent*),

We live unto God (*consequent*).

ANTENNA

ANTECEDENT. In Mathematics, the name given to the first of the two terms composing a ratio. Thus in the ratio $a : b$, a is the antecedent, and b is denominated the consequent.

Antediluvian (Lat. ante, *before*, and diluvium, *deluge*). Anything that existed before the deluge. This term is sometimes used by geologists to designate the period anterior to the presumed Noachian deluge. In this sense it is used chiefly in reference to human history. There is no physical evidence of any single deluge that could have affected the whole surface of the globe during any geological period, and thus the expression is without a literal meaning in geology. It is therefore seldom employed, and when it is, it is meant to refer to the Noachian deluge only.

Ante-fixæ (Lat.). The lions' heads, or other ornaments, which are introduced below the line of the eaves of a temple, through the perforations of which the water is allowed to escape, usually through the mouths, so as not to fall upon the foundations; in this respect it resembled the gargouilles of Gothic architecture. By some writers on architecture this term is used to denote the upright ornaments above the eaves in ancient buildings, which concealed the ends of the harmi, or of the joint tiles, without reference to their function of water-bearers.

Antelope. [ANTILOPE.]

Antenati (Low Lat. born *before*). In English law, a phrase applied to Scots born before the union of the crowns under James I., who were considered aliens in England, while the postnati, born in Scotland after that event, claimed the rights of native subjects of the English crown.

Antenna (Lat.). A moveable, tubular, and jointed sensiferous organ situated on the head, and peculiar to the *Condyllope articulata*. Certain Annelides carry soft tentacles or filaments upon the head, which have been termed antennæ; but improperly, according to the above definition, which would restrict the phrase to the jointed antennæ of insects and crustaceans. In the latter class the antennæ are commonly four in number, consisting each of a 'scape,' a 'pedicel' of two joints, and a 'clavoleit;' the latter is setaceous, and divided into a vast number of minute joints. It is simple in the external antennæ, but in the internal pair is always composed of two and sometimes of three setaceous filaments. The internal pair of antennæ are situated before or between the eyes, the external behind, at the outer sides of the eyes. In insects the antennæ are always two in number, and situated in the space between or before the eyes; they consequently correspond to the internal antennæ of crustaceans. The cavity or socket in which the base of the antennæ is planted is called the 'torulus,' or bed. The first, and in many cases the most conspicuous, joint of the antennæ is termed the scape. The base of the scape, by which it is articulated with the torulus, is the bulb. It often looks like a distinct joint, and is the point upon which the antenna turns. The

ANTENNULÆ

pedicellus, or second joint of the antenna, in some insects, also acts the part of a pivot in the bed of the scape, in order to give a separate motion to the clavola, or clavolet. This, which includes the remaining joints of the antenna taken together, is occasionally terminated by a capitulum or knob; a term applied to the last joints of the clavolet when suddenly larger than the rest. [For the varieties of antennæ with respect to situation, approximation, proportion, direction, figure, termination, and appendages, the reader is referred to the 4th vol. of Kirby and Spence's *Introduction to Entomology*.]

Antennulæ (dim. of antenna). A term sometimes applied to the articulated filaments attached to the jaws or lower lip of Mandibulate insects, and which seem to be endowed with a sensiferous faculty specially adapted to distinguish kinds of food, and applied by the animal to that use: these organs are more commonly called palps, palpi, or feelers.

Antepectus. In Entomology, signifies the under-side or breast-plate of the main trunk, and the bed of the first pair of extremities or arms.

Antepenult, or **Antepenultima** (Lat.). In Grammar and Prosody, the last syllable of a word but two.

Antepilani (Lat.). A name given to the two classes of soldiers in the Roman army called Hastati and Principes, as being drawn up (*ante pila*, i.e.) before the Triarii, who were armed with the pilum or long spear.

Anterior (Lat.). In Botany, this is said either when of two lobes of a stigma one, the anterior, is directed towards the front of a flower, and the other, the posterior, towards the back, or in any similar case. It is also applied to certain stipules, which stand between the petiole and stem of a plant, adhering to the former, as in some Cinchonaceous plants.

Antesignani (Lat.). A name given to the class of Roman soldiers called Hastati, as standing in front of the standards (*ante signa*) of the maniples.

Anthelia (Gr. ἀνθελίαι, *opposite the sun*). Luminous coloured rings, or glories, observed under certain conditions round the shadow of the spectator's own head. The conditions of the phenomenon are two: first, that the sun be near the horizon, and secondly, that the shadow be projected on a surface covered with dew drops as a field of grass or stubble, or on a dense cloud or fog-bank, distant about 50 or 60 yards. Generally the luminous appearance is very faint, and only one or two rings can be traced; but sometimes, in favourable circumstances, it is strikingly vivid, and two or three small concentric circles appear, surrounded by a much larger one, of whitish light, the head of the observer's shadow being at the common centre. Such brilliant Anthelia were observed by Bouguer and his companions on the clouds of the Andes (*Figure de la Terre*, p. 43), and by Scoresby on the fog-banks in the Arctic seas. Scoresby gives the following dimensions of the rings as measured by him on one occa-

ANTHER

sion: radius of the first or innermost ring 2° ; of the second $4^{\circ} 45'$; of the third $6^{\circ} 30'$; and of the outermost $38^{\circ} 50'$. The cause of interior rings is thus explained by Fraunhofer. Light falling directly from the sun on the anterior side of an aqueous globule undergoes a refraction, and a portion of this refracted and consequently coloured light on falling on the interior surface of the opposite side of the globule is reflected back to the eye of the spectator. The large surrounding circle is supposed to be formed by a double reflection, as in the case of the ordinary rainbow. [HALO.]

Anthelix (Gr. from ἀντή, and ἑλῖξ, *the helix*, or external involute margin of the auricle). In Anatomy, the outer or external ridge of the auricle ear, which runs nearly parallel with the helix.

Anthelmintics (Gr. ἀντή, and ἑλμινς, *a worm*). Medicines which kill intestinal worms, or effect their expulsion.

Anthem (probably the same derivation as Antiphon). In Modern Music, is a term used for any church vocal composition more important than a psalm tune.

Anthemion (Gr.). That ornament or ornamental series used in Greek and Roman decoration, which is derived from floral forms, more especially the honeysuckle, very common in the early period of Greek art. It was much used for antefixes and friezes in architecture, and for interior decoration; also for the painted decoration of fictile vases, and for the borders of dresses. The so-called honeysuckle is alternated generally with some other floral form, as in the excellent examples in the British Museum from the Erechtheum and from the temple of Apollo Epicurius. (Wornum, *Analysis of Ornament*, 1859.)

Anthemis (Gr. from ἄνθος, *a flower*). The hamemile, one of the most useful of our native tonic bitters, belongs to this genus of composite plants. It is the *A. nobilis* of botanists, and is abundant on waste common land, where its prostrate stems form part of the turf. Its stimulant tonic properties make it useful in cases of weak digestion.

Anther (Gr. ἀνθήρα, *a flowery herb*). A hollow case, usually consisting of two parallel cells, and constituting the apparatus that contains the pollen, or male part of a flower. Theoretically considered, an anther is the blade of a leaf, in a contracted state, with its two sides hollowed out and its parenchyma converted into pollen, while the midrib in a fleshy state divides the two lobes, and is called the connective. This part is sometimes highly developed, when the lobes of the anther are often placed at a distance from each other, as in *Nymphaea*; or it is altogether absorbed, when the lobes run together, and there is but one cell, as in *Euphrasia*. Other modifications produce other striking appearances: one lobe, for instance, disappears, and the connective is expanded into the state of a petal, as in *Canna*; or it is simply lengthened and distorted, as in *Salvia*; or, the anther remaining in its normal

ANTHESIS

state, it is converted into a fleshy mass, as in *Penæa*; and it undergoes many similar transformations, either from the same or other causes. What is most curious about the anther is its property of opening to discharge its pollen just at the very time when the stigma is ready to receive the influence of the latter. The cause of this sympathy between two really independent parts is supposed to consist in an emptying and drying up of the cellules forming the lining of the anther by the absorbent action of the ovary, which, it is imagined, by its own efforts thus brings about an action which is necessary to its own complete operation. The cellules lining the anther, when thus dried up, contract, and pull against certain fissures or dehiscent lines in the valves of the anther, which give way, and so form openings by which the pollen escapes; or heat is evolved and the cases are thus burst.

Anthesis (Gr. ἀνθήσις). The period when flowers expand. It is at that time that all the curious phenomena of fertilisation occur, and the parts are all in their most perfect state.

Anthodium (Gr. ἀνθώδης, *full of flowers*). The head of flowers of a 'histle or daisy or other composite plant; it is the same thing as capitule, and is applicable to all cases where a number of small flowers or florets are combined in a head, and surrounded by a common involucre. An anthodium is nothing but a depressed spike.

Anthology (Gr. ἀνθολογία, *a collection of flowers*). In ancient literature metaphorically applied to a collection of short pieces of poetry on amatory, convivial, moral, funeral, &c., subjects. The first collection known by the name of Anthology was made by Meleager, a Syrian Greek poet, who lived about a century before the birth of Christ; to this additions were made by different hands as low down as the times of the Byzantine empire, and it has been several times edited by modern scholars.

Antholysis (Gr. ἄνθος, *a flower*, and λύσις, *breaking up*). The changes of flowers from their usual to some other state, as leaves, branches, &c.

Anthophorum (Gr. ἀνθοφόρος, *bearing flowers*). A columnar process arising from the bottom of the calyx, and having at its apex the petals, stamens, and pistil. It is usually very short, and is in reality an internode between the whorls of sepals and petals.

Anthophyllite (Gr. ἄνθος, and φύλλον, *a leaf*). A kind of Tremolite occurring in masses of acicular fibres, of a grey or clove-brown colour, with an occasional blue tinge and a glistening pearly lustre. It is found in Norway, Greenland, and Connecticut.

Anthosiderite (Gr. ἄνθος, and σίδηρος, *iron*). A hydrated silicate of iron occurring in fine fibrous tufts, with a radiated structure and of an ochreous-yellow and yellowish-brown colour, at Antonia Pereira in Minas Geraes in Brazil, associated with Magnetite.

ANTHRAX

Anthoxanthum (Gr. ἄνθος, and ζαῖθος, *yellow*). A dwarf annual grass, found plentifully in pastures, and having sweet-scented leaves, the scent depending on the presence of coumarin. There is no doubt the fragrance of hay is owing to its presence. The flowers are in oval heads, which become dull yellow when ripe. Farmers call it the sweet vernal grass.

Anthozasia (Gr. ἄνθος, and ζῶσα, *I live*). When the leaves of a plant assume the appearance of petals.

Anthozoa (Gr. ἄνθος, and ζῶον, *animal*). The class of Corals, and Actiniae, also termed Actinozoa. They are divisible into the following families:—

- Family Actiniidæ.
- „ Zoanthidæ.
- „ Xenidæ.
- „ Aleyonidæ.
- „ Pennatulidæ.
- „ Tubiporidæ.
- „ Caryophyllidæ.
- „ Gorgoniadæ.

Anthracin. A solid crystalline hydrocarbon, accompanying naphthalin in the distillation of coal tar.

Anthracite (Gr. ἄνθραξ, *charcoal or coal*). A variety of coal containing, when pure, hardly any volatile ingredients, and in some cases consisting almost exclusively of carbon. Very large quantities of anthracite occur in the coal fields of South Wales, and much larger deposits exist in North America.

Anthracite burns with intense heat and very slowly, but it requires a peculiar structure of the furnace to allow it to be used economically. It requires a strong draught, and the carbonic oxide formed during combustion does not, without special arrangement, circulate in long tongues of flame, such as are used to get up steam rapidly. Hence it was long after other coals were in common use that anthracite was rendered available for steam power. It is now used both for ordinary furnace purposes, and in the manufacture of iron, and is a very valuable fuel.

In Pennsylvania, in North America, is a very remarkable series of anthracite beds, extending over a quarter of a million of acres of ground. There are here sixteen workable seams, the thickest being as much as thirty feet. Other deposits of smaller magnitude occur elsewhere, but there are none containing such thick masses or so many beds.

Anthraconite. [STINKSTONE.]

Anthracotherium (Gr. ἄνθραξ, *charcoal*, and θηρίον, *a beast*). A name indicative of the stratum in which the fossil genus of Pachyderms, to which it is applied, was found, viz. in the tertiary Miocene coal or lignite of Cadibona, in Liguria. The genus presents seven species, some of them approximating to the size and character of the hog; others approaching nearly to the dimensions of a hippopotamus.

Anthranilic Acid. A solid crystalline body derived from indigo.

Anthrax (Gr.). The name of a Fabrician

ANTHRAX

genus of Dipterous insects, having the mouth provided with a very long straight setaceous sucker formed of two unequal horizontal valves, and containing setaceous stings; palpi two, hairy; antennæ distant, the last joint setaceous. The genus is now raised to the rank of a family, *Anthracide*, characterised by a short body; wings spreading widely out; antennæ distant, two and sometimes three-jointed; the head as high as the thorax. Two of the genera (*Somatia* and *Anthrax* proper) are British.

ANTHRAX. A carbuncle. A hard circumscribed tumour, resembling in colour a glowing coal.

Anthrenus. The name of a Linnæan genus of Coleopterous insects, having the antennæ clavate, the club solid; palpi unequal, filiform; maxillæ membranaceous, linear, bifid; labium entire; head hid under the thorax.

Anthribus. The name of a Fabrician genus of Coleopterous insects, applied to that section of the Linnæan *Curculiones* which has the lip bifid, the jaw bifid and short, and the proboscis short.

Anthropology (Gr. *ἄνθρωπος*, a man, and *λόγος*, a science). The science of Man and Mankind; subordinated under three great heads: *Ethnology*, or the study of the races of men; *Archæology*, or the study of the past evidences of man's existence; and *Ethnography*, or the study of man's works.

Anthropomorphites (Gr. *ἄνθρωπος*, and *μορφή*, form). Persons who conceive the Deity to have naturally the human shape. Such sensuous conceptions of the nature of God have been always common among heathens.

Anthropophagi (Gr. *ἄνθρωποφάγος*). People who feed upon human flesh.

Anthurus (Gr. *ἄνθος*, a flower, and *οὐρά*, a tail). A spike of minute flowers arranged closely on a long axis, as in the genus *Piper*.

Anthus. The name of a subgenus of Passerine birds, including the pipits.

Anti (Gr. *against*). This Greek preposition is constantly used as a prefix to express opposition; thus, antidote, antibilious, antipathy, &c.

Antiar. [UPAS.] A Javanese poison.

Antiarine. The poisonous principle contained in the milky juice of the *Antiaris Toxicaria*, a large forest tree growing in Java. This poison acts upon the brain and spinal marrow, and paralyzes the heart.

Antiaris (Jav. antja). The upas tree of Java belongs to this genus of *Artocarpacæ*. The tree, which attains considerable size, secretes a milky juice which contains a most virulent poison, the antiar poison of Java, though extremely exaggerated statements have been made respecting its influence on animal life. It was said to grow in a desert with no other vegetation within miles of it, and to destroy all living creatures which approached it; but it is now known to grow in woods amongst other trees, and birds and lizards have been observed on its branches. It is, however, a very dangerous poison, and severe effects have

ANTICLINAL AXIS

been felt by persons merely climbing the trees: the dried juice, moreover, is most venomous.

Anti-attrition. A compound applied to machinery to prevent the effects of friction. It frequently consists of a mixture of plumbago with some greasy material.

Antibrachium (Gr. *ἀντί*, and *βραχίον*, arm). The fore-arm, or third segment of the anterior extremities, which is formed, in the skeleton, by the radius and ulna conjointly; or sometimes by the radius, either alone, or with the ulna partially developed. And the forearm articulates, above with the arm, below with the hand.

Anticardium (Gr. *ἀντί*, and *καρδία*, the heart). In Anatomy, the cavity under the breast, which is just against the heart, and is called the pit of the stomach.

Antichlor. Sulphite of Soda is so called, because used in removing the last traces of chlorine from bleached paper pulp.

Antichrist (Gr. *ἀντίχριστος*). Mentioned by St. John, 1st Ep. ii. 18, and supposed to be the same with the 'man of sin' whose coming is foretold by St. Paul, 2 Thess. ch. ii. The speculations in which theological writers have indulged respecting this great adversary of Christianity have been various and most fanciful. At the council of Gap, in 1603, the reformed ministers there assembled, inserted an article in their Confession of Faith, in which the pope is pronounced Antichrist. Grotius, and most catholic divines, consider Antichrist as symbolical of Pagan Rome and her persecutions; Leclerc, Lightfoot, and others, find in the term a symbol of the Jewish Sanhedrim, or of particular Jewish impostors.

Antichthon (Gr). In Greek astronomy, an imaginary world, in the scheme of the Pythagorean Philolaus. It is a body distinct from the earth, and nearer to the central fire. Aristotle ascribes the idea of the Antichthon to the Pythagorean doctrine of the properties and virtues of numbers. (Sir G. C. Lewis, *Astronomy of the Ancients*, ch. ii. sect. 17.)

Anticlimax. In Architecture, an anticlimax is said to have been attained, when the original composition is succeeded by a motive of the same character, but upon a much diminished scale to that of the principal member of the series. Thus, the domes of Somerset House, and of the National Gallery, may be cited as illustrating the precise relations of an 'anticlimax' to the primary motive of the composition of those buildings.

ANTICLIMAX (Gr. *ἀντί*, and *κλίμαξ*, gradation). In Rhetoric, when a sentence or discourse, instead of ascending from little to great, descends from great to little. Horace has given a famous example,

Parturiunt montes, nascetur ridiculus mus.

There are also several striking examples of this figure in Pope, as in the verse,

Die, and endow a college or a cat.

Anticlinal Axis (Gr. *ἀντί*, and *κλίνειν*, to incline). If a range of hills or a valley

ANTICLINAL LINE

be composed of strata which, on the two sides, dip in opposite directions, the imaginary line that lies between them, towards which the strata on each side rise, is called the anticlinal axis. In a row of houses with steep roofs facing the south, the slates represent inclined strata dipping north and south, and the ridge is an east and west anticlinal axis (Lyell). In the annexed diagram, *a a* are the anticlinal, and *b b* the synclinal lines.

Anticlinal and Synclinal Line. In Geology, the imaginary line from either side of which strata are seen to dip in opposite directions. It is not uncommon, in cases where strata have been disturbed from their original horizontality, to find some parts of a series of strata in a ridge or saddle-shaped position, having been apparently lifted by a linear upheaving force. The line of this force is called an **Axis** or **ELEVATION**, and if two such are parallel, the beds between will occupy the position of two ridges and a furrow. The ridge is an *anticlinal*, and the furrow a *synclinal* axis. Excellent examples of anticlinals are seen in the Jura mountains, where the mountain chain lies in the direction of the axes of this kind. The phenomena are also common in the western parts of England, throughout the country from north to south. An inverted V (*A*) represents a transverse section of a bed raised by an anticlinal; but the angle has often been broken away and rounded, thus giving the saddle-shape. The V in its usual position represents a bed bent by a synclinal. Saddle and trough are terms sometimes used instead of anticlinal and synclinal. The result of an anticlinal is not infrequently a 'VALLEY OF ELEVATION' [which see]. Synclinals are often hardly indicated at the surface; but they sometimes produce natural valleys, either alone or in systems of several parallel to each other, separated by anticlinal ridges.

Anticous. In Botany, is applied to an anther whose lobes are placed facing the style; or to a petal which is stationed on that side of a flower which is next the eye of an observer as it grows upon its stem.

Antifriction. Any arrangement of machinery by which the resistance to motion by friction is opposed is called 'antifriction.' This term is especially applied to a description of alloy destined for this purpose, composed of bell metal, or aluminium bronze, both of which enjoy the faculty of opposing the least resistance to motion of any possible varieties of metal in union with the greatest resistance to the effects of friction, as far as regards the wearing away of the surfaces of contact.

Antigorite. A species of Serpentine in which a portion of the silica is replaced by alu-

ANTIMONIC ACID

mina; lustre weak; feel smooth but not greasy. It is found in the Antigiora Valley, in Piedmont.

Antigugler. A siphon, so inserted into casks or carboys as to admit air over the liquor contained in them, and to allow of its being poured out without agitation.

Antilegomena (Gr. *things spoken against*). In Theology, a term applied to those books of the New Testament concerning the authority of which there were disputes in the church, although they were ultimately received into the canon; namely, the Second Epistle of Peter, those of James and Jude, that to the Hebrews, the Second and Third of St. John; and the Apocalypse.

Antilogarithm. In its most common acceptance, denotes the number to a logarithm. Thus, in the common system of logarithms, 100 is the antilogarithm of 2, because 2 is the logarithm of 100. Sometimes the term is used to denote the complement of the logarithm, or the difference of the logarithm from the next higher term in the series, 1, 10, 100, &c.

According to the notation of inverse functions the antilogarithm of x would be represented by $\log^{-1}x$; thus $\log^{-1}2 = 100$.

Antilolimo (Gr. *ἀντί*, and *λόιμος*, pestilence). Remedies used in the prevention and cure of the plague.

Antelope. Antelope: a term which, according to Cuvier, is a corruption of the word 'antholops,' applied by Eustathius, an ancient naturalist, to the gazelle, in allusion to its beautiful eyes. The name is now given to a division of the hollow-horned Ruminants [*CAVICORNIA*], in which the bony axis of the horn is without cavities or sinuses. Antilopes are further distinguished by suborbital or maxillary glandular pouches, and their light and elegant figure. They are the natives, for the most part, of the wildest and least accessible places in the warmer latitudes of the globe; frequenting the cliffs and ledges of mountain rocks, or the verdure-clad banks of tropical streams, or the oases of the desert. They traverse the intervening wildernesses in pairs or in troops with incredible fleetness, clearing obstacles, which would impede the course of other quadrupeds, by a succession of agile bounds.

The antelopes are now arranged under a number of subgeneric divisions, according to the form of the horns, which are peculiar to the male. Forty-seven species are known, which, with one or two exceptions, are peculiar to the Old World.

Antimonial Copper. Native sulphide of copper and antimony. [*WOLFSBERGITE*.]

Antimonial Copper Glance. [*WOLFSBERGITE*.]

Antimonial Nickel. [*ULLMANNITE*.]

Antimonial Ochre. The name given to a hydrated antimonious acid, which occurs in earthy masses and as a pulverulent crust. [*CERVANTITE*.]

Antimonial Silver. [*DISCRASITE*.]

Antimonic Acid. The peroxide of antimony. [*ANTIMONY*.]

ANTIMONITE

Antimonite. A mineralogical synonym for native sulphide of antimony or grey antimony ore. [STIBNITE.]

Antimony. A brittle metal of a silver white colour; specific gravity, 6.7. Fuses at 810°, or just at a red heat. The principal properties of this metal were first described in the *Curus Triumphalis Antimonii* of Basil Valentine, published towards the end of the thirteenth century. When heated in an open vessel, it gradually combines with oxygen, and evaporates in a white vapour. There are three oxides of antimony. The protoxide consists of 65 antimony + 12 oxygen: it is a greyish white powder, eminently purgative, sudorific, and emetic; and as such, of much importance in medicine. It is the active base of emetic tartar and of James's powder. The other oxides of antimony, from combining with certain bases, have been called antimonious and antimonie acid; they consist respectively of 65 antimony + 16 oxygen, and 65 + 20. The combination of chlorine and antimony was known to the old chemists under the name of *butter of antimony*. The principal ore of antimony is the *sulphuret*: it is met with in commerce, melted into conical ingots, under the name of crude antimony. It is of a bluish grey colour, metallic lustre, and a striated texture; specific gravity 4.62; it is much more easily fusible than the pure metal. Antimony forms brittle alloys with some of the most malleable metals: when gold is alloyed with a two-hundredth part of antimony, the compound is brittle; and even the fumes of antimony in the vicinity of melted gold are sufficient to render it brittle. Alloyed with lead in the proportion of 1 to 16, and a small addition of copper, it forms the metal used for printers' types: with lead only, a white and rather brittle compound is formed, used for the plates upon which music is engraved. With iron it forms a hard whitish alloy, formerly called *martial regulus*: 12 parts of tin and 1 of antimony form hard pewter. The white metal spoons and teapots are formed of an alloy of 100 tin, 8 antimony, 2 bismuth, and 2 copper.

Antimony is the *stimm*, or *stibium*, of the old chemists.

Antinomians (Gr. *ἀντί*, and *νόμος*, law). Oppugners of the law. In Theology, Antinomians are such as interpret the law, to which St. Paul refers more especially in the Epistle to the Romans, as including all moral ordinances whatsoever; and push the contrast which the Apostle maintains between faith and the works of the law to an extreme extent, asserting the entire uselessness of good works in any case, and the sole efficacy of faith. Hence the term Solifidian is applied to the same class of religionists. The name of Antinomian was first given by Luther, as a term of reproach, to the followers of the opinions of John Agricola on this subject, who complained, however, that his notions had been unfairly represented. Similar doctrines appear to have been held in England by an ephemeral sect in the time of the commonwealth: but the word

ANTIPODES

Antinomianism may now be taken rather as expressing the extreme to which the Calvinistic scheme of theology has the tendency to lead men, than as denoting the creed of any distinct sect or congregation, either in this country or abroad.

Antipædobaptists. In Theology, those who object to the baptism of infants on the ground that they are not capable of understanding the nature of the rite, and of pledging themselves to such a course of life as is required of all such as come to be baptized. [BAPTISTS.]

Antiparallel or Subcontrary. In Geometry two pairs of right lines in the same plane are said to be *antiparallel* or *subcontrary* when equal and opposite quantities of turning applied to the lines of either pair bring them into coincidence with the other pair. For instance, the two pairs of opposite sides of a quadrilateral inscribed in a circle are antiparallel.

Two circular sections of a quadric cone planes intersect are also sometimes called antiparallel or subcontrary.

Antipathes. A genus of Corticiferous Polypes, or corals, in which the central axis is enveloped by so soft a cortex that it falls off when the specimen is removed from the water. From the colour of the axis, it is commonly called 'black coral.'

Antipathia (Gr. *ἀντιπάθεια*). The *antipathic method* in Medicine, consists in the use of remedies which produce effects of an opposite nature to the symptoms of the disease: the maxim adopted is '*contraria contrariis opponenda*.' Hippocrates may be regarded as the founder of this doctrine.

Antipedes (Lat. *ante*, before, *pes*, foot). In Zoology, the anterior or pectoral extremities, formed by the diverging appendages of the occipital segment of the skull.

Antipeliargia (Gr. *ἀντί*, and *πελαργός*, a stork). The *Lax ciconiaria*, an old law by which children were compelled to nourish their aged parents. The Ciconia, or stork, is famous for the care it takes of its parents, and hence the Latin name.

Antiperistaltic (Gr. *ἀντί*, and *περιστέλλω*, I wrap up). That movement of the intestinal tube which is retrograde or contrary to the proper course impressed upon the contents by the ordinary vermicular or peristaltic action.

Antiphlogistic Treatment (Gr. *ἀντί*, and *φλόγωσις*, inflammation). In Surgery, the means of removing or lessening inflammation, and of obviating its effects.

Antiphon (Gr. *ἀντιφωνος*). A piece of music performed in cathedral service by choristers who sing alternately. This manner of singing is very ancient in the church; some suppose it to have descended from the practice of the earliest Christians, who, according to Pliny, were accustomed to sing their Hymn to Christ in parts or by turns (*secum invicem*). The antiphon, in ancient church music, is the short verse sung before the psalms and other portions of the service.

Antipodes (Gr. *ἀντί*, and *πούς*, the foot).

ANTIPOPE

Denotes, literally, those who stand feet to feet; that is, the inhabitants of opposite parts of the earth. They live under the same parallels of latitude, on opposite sides of the equator; consequently the seasons are reversed, i.e. when it is summer to the one, it is winter to the other. Their longitude differs by 180°, or 12 hours; consequently their days and nights are reversed; that is, when it is mid-day to the one, it is midnight to the other. They have the same climate; in so far, at least, as climate depends on latitude.

Antipope. One that assumes the title and functions of pope without a valid election. The term more particularly refers to the popes who maintained themselves in opposition to each other during part of the fourteenth and fifteenth centuries. The great western schism was caused by the rival jealousies of the French and Italian parties in the conclave; the French cardinals having been accustomed by their numbers and the influence of the kings of France, to carry the election in favour of French candidates, while the popes resided at Avignon, a period of about 70 years from 1305 to 1376. Accordingly, when the Italian party at last succeeded in the election of Urban VI., in 1389, the French cardinals retired from Rome, and there invested with the functions of pope one of their own body, under the title of Clement VII. They attempted, in the first instance, to maintain themselves in Italy, and war was proclaimed between the two rivals. After a short struggle, Clement retreated to Avignon, and there he, and his successor, Benedict XIII., held their court; while Urban, and after him Boniface IX. and Gregory XII., reigned at Rome. They were supported respectively by different European states, of which France, Austria, Castile, Aragon, Savoy, Genoa, and Scotland sided with the party of the seceders. The schism caused great scandal throughout Christendom, and measures were repeatedly taken, and baffled only by the artifices of the rival claimants, for an adjustment of the difference. However, in 1409, the rival parties were both declared by the Council of Pisa guilty of heresy and schism, and thereby the validity of both claims greatly disproved. Alexander V. was then elected in due form; and the antipopes were unable long to maintain their pretensions against the authority of a general council.

Antiquary. Copiers of old books, especially in convents, were termed *Antiquarii* in the Latin of the middle ages. In modern phraseology, antiquary is defined 'a person who studies and searches after monuments and remains of antiquity, as old medals, books, statues, inscriptions, &c.:' to which may be added those who make the manners and customs of ancient times an especial subject of inquiry. Henry VIII. gave Leland the title of his 'Antiquary.' The Royal Society of Antiquaries, in London, was founded under the reign of George II. [ACADEMY.]

Antique. The term especially employed to convey the meaning of an ancient or of a very

ANTIQUITIES

early monument. There are as many interpretations as to the meanings of the word as there are sentiments with regard to antiquity, and the word 'antique' has therefore been applied in a countless variety of manners. The general acceptance of the word is, however, understood to be that of a period antecedent to the revival of the classical studies in Western Europe, or before the *risorgimento*, or *renaissance*, of the arts from their assumed period of lethargy. There was, in fact, a distinct character about the productions of the artists of the more ancient and the more modern times, which was sufficiently marked to produce in the best of them a separate style of art, and which has led to the establishment of the schools of the so-called antique and modern styles; the mediæval arts form as it were an intermediate class, which was as distinctly marked as any of the other styles. The antique school was distinguished by an anthropomorphism and a divination of the human form; the mediæval school was formed upon, and characterised by, a species of contempt for the human figure, and an aspiration after an ideal perfection, and therefore there is something vague and undefined in its efforts to represent the objects it copied; whilst the modern school has united the indefiniteness of its aim with that clearness of the perception of its objects, which is so marked a characteristic of its productions. The antique schools date from the dawn of civilisation to the end of the tenth century; the mediæval schools date from the tenth to the fifteenth centuries; and the modern schools have continued the traditions of the masters of art to the present times. The works of the various authors are respectively known by the names of their actual schools, and are called antique, mediæval, or modern, as they belong either to the one or the other of them.

Antiquities. Under this term, which has not a very definite meaning in modern European languages, we appear generally to comprehend all memorable things respecting Man in his social state in past time, except the political events, which form more properly the subject of History. Thus, manners and customs, language, literature, topographical details, the monuments of architecture, sculpture, &c., of ancient times, all fall under the general cognisance of the antiquary. His science is, as it were, subsidiary to the more general objects of the historian. In a more restricted sense, the study of antiquities is confined to the description and interpretation of the existing relics of former times, such as architectural remains, manuscripts, medals, and other objects of curious research. Among classical writers, there is, perhaps, only one who falls exactly within the definition of what in modern times we should term an antiquary; viz. Pausanias, whose work, written about the period of Marcus Antoninus, is entirely devoted to a description of the monuments of earlier periods then existing in Greece. But about the time of the revival of letters, when the study of classical

ANTIQUITIES

writers became the main pursuit of literary men, classical antiquities became also a distinct and important branch of research. Besides the writers who employed their antiquarian knowledge in the shape of commentary on classical authors, a great number devoted their talents to the production of treatises exclusively illustrating particular points in ancient customs and usages. The following older works may be named as among the most comprehensive and general which we possess, containing an immense repository of facts, which the more refined criticism of modern times has sifted and applied with better success: the treatises of *Signonius* and *Meursius*—the latter chiefly on Greek antiquities—collected in twelve folio volumes; Florence, 1741: the vast *Thesaurus Antiquitatum Græcarum* of the Dutch commentator Grævius (Leyden, 12 vols. fol. 1697, &c.); and the still more extensive work of Gronovius (*Thesaurus Antiquitatum Romanarum*, Leyden, 13 vols. fol. 1697), together with its continuations and supplements, by Burmannus, extending in the whole to 45 volumes; the works of Polenus, Pitiscus, and Gruterus, on the same plan with those two vast collections; the *Antiquité Expliquée* of Bernard de Montfaucon, extending, with the supplements, to 16 vols. folio, Paris, 1719–24. From these great works our modern Compendia in common use are chiefly compiled. The names of Boeck (*Public and Private Economy of Athens*), Heeren (*History of Ancient Commerce, &c.*), Müller, Niebuhr, Creuzer, Böttiger, Wachsmuth, &c., attest the equal industry and superior critical skill of the classical antiquaries of modern Germany, the country in which this branch of knowledge is most successfully cultivated; while in England many distinguished scholars, such as Arnold, Grote, and Sir George Lewis, have followed the same or a similar path. Dr. Smith's valuable series of Dictionaries may now be referred to as comprising the results, well sifted, of earlier diligence in this great study. In that more restricted branch of classical antiquities, the description of the monuments of ancient art, among many illustrious names we may mention those of Caylus (*Recueil d'Antiquités Egyptiennes, Grecques, et Romaines*, 7 vols. 4to, Paris, 1752, &c.) and the Abbé Winkelmann. In the peculiar study of Egyptian antiquities, the names of Young, Hamilton, Champollion, Bunsen, and Sharpe, stand pre-eminent. In ecclesiastical antiquities, the huge collections of Ugolinus (*Thesaurus Antiquitatum Sacrarum*, 34 t. fol. Antv. 1744) and Canisius (*Lectiones Antiquæ*, edited by Basnage, 4 t. fol. v. Antv. 1726) may be mentioned among many others. Lastly, the antiquities of the middle ages have received much and accurate attention, especially in France and England, within the last century. Besides the works of Leland and Camden, the fathers of English antiquities, of Dugdale and Hearne, &c., we may name in modern times, Fosbrooke (*British Monachism*, 2 vols. 4to. 1802, and *Encyclopædia of Antiquities*), Strutt (*Regal and Ecclesiastical Antiquities of Eng-*

ANTITYPE

land, &c. 1773, and many subsequent works). Brand, Lodge, Playfair, &c. &c., besides many who have devoted themselves to particular branches of the subject; and, among later authors, Sir Henry Ellis, Sir F. Palgrave, Sir H. Nicolas, Mr. Petre, W. Wright, &c. In French antiquities, the greatest name is that of Montfaucon (*Monumens de la Monarchie Française*, 5 vols. fol. Paris, 1726, &c.); while the Italians, among whom the study of national antiquities has been very sedulously cultivated, are peculiarly indebted to the indefatigable Muratori. His principal works are the *Antiquitates Italicæ Medii Ævi*, and *Rerum Italicarum Scriptores*: the whole are said to amount to 41 vols. in folio, besides 34 in 8vo.

Antirrhineæ. A small division of Scrophulariaceæ plants, consisting of *Antirrhinum* (the snap-dragon of the gardens), *Linaria*, and a few other genera.

Anticell, or Antiscians (Gr. ἀντί, and σκιά, shadow). An old term used in Geography to denote those inhabitants of the earth whose shadows fall in opposite directions. The inhabitants of the north and south temperate zones are always Antiscians; those living within the tropics may be Antiscians at one season of the year, and not at another.

Antiscorbutics (Gr. ἀντί, and scorbutus (a barbarous Latin word), scurvy. Medicines against the scurvy.

Antiseptic (Gr. ἀντί, and σφραῖν, to putrefy). Antiputrefactive. Substances which prevent or check the putrefaction and decay of animal and vegetable matter, are called antiseptic.

Antispasmodics (Gr. ἀντί, and σπασμός, a spasm). Medicines which alleviate or cure cramp and spasm.

Antistrophe. [STROPHÆ.]

Antithesis (Gr.). In Rhetoric, a figure in which two thoughts, words, or sentences are set in opposition to each other, in order to be more strikingly brought forward by the contrast; as in the following sentence from Cicero: 'Quod scis, nihil prodest: quod nescis, multum obest.' 'Your knowledge avails you nothing: your ignorance hurts you much.' Quintilian translates the Greek word ἀντίθεσις by the Latin *contrapositum*.

Antitragus. In Anatomy, the process of the external ear opposite the tragus, and behind the *meatus auditorius*, or ear-passage.

Antitropal (Gr. ἀντί, and τρέπω, to turn). When in a seed the radicle of the embryo is turned to the end farthest away from the hilum. This, although a comparatively unusual position of parts, is nevertheless the normal position, if the exact nature of the development of an ovule is rightly understood.

Antitype (Gr. ἀντίτυπος). Literally, a copy, answering to the type which determines its character. In Theology the term denotes the person in whom any prophetic type is regarded as fulfilled. Thus if Moses guiding the Israelites to the promised land, be considered

ANTLIA

as a type, Christ is the antitype as guiding the redeemed to their rest in heaven. In this sense the type is always inferior to the antitype.

Antlia (Gr.). The oral instrument of Lepidopterous insects, in which the ordinary trophi, or instruments for obtaining, are replaced by a spiral, bipartite, tubular machine for suction, with its appendages. It principally consists of the solenaria, or two lateral subcylindrical tubes, and the fistula, or intermediate subquadrangular pipe, formed by the union of the two solenaria, which intermediate canal conveys the nectar to the pharynx. Theoretically and morphologically the solenaria are the maxillæ inordinately elongated, which support at their bases two minute palpi. Rudiments of the upper lip or labrum, and mandibles, exist above the maxillæ; and below these is the labrum, attached to the head, and distinguished by a pair of large palpi.

Antlia Pneumatica. A constellation of the southern hemisphere, so called from its supposed resemblance to an air-pump.

Antlion. [MYRMELONIDES.]

Antoeci (Gr. *ἀντί*, and *οἶκος*, a house) Those who live over against each other; term used in Geography to denote the inhabitants of the globe who live under the same meridian, but on opposite parallels of latitude. The hours of the day are the same to each, but the seasons are opposite; when it is summer with the one, it is winter with the other.

Antoninus, Itinerary of. An exceedingly valuable geographical work, extending over the whole Roman empire, and containing the distances on all the Italian and provincial roads, as well as from port to port. The date and author of the work are unknown.

Antoninus, Wall of. A turf entrenchment, raised by the Romans across the north of Britain, under the direction of Lollius Urbicus, legate of Antoninus Pius, about A.D. 140, and is supposed to have connected a line of forts erected by Agricola in A.D. 80. It extended from Dunglass Castle, on the Clyde, to Caer Ridden Kirk, near the Frith of Forth; and included a rampart and ditch, with nineteen forts, the mean distance between each fort being rather more than 2 English miles.

Antonomasia (Gr. from *ἀντί*, instead of, and *ὄνομα*, a name). In Rhetoric and Composition, a figure by which a proper name is put for an appellative noun; as where a tyrant is called a Nero, an usurper a Cromwell, &c.: or, vice versa, a complimentary periphrasis, or an appellation derived from some attribute, is put for a proper name; as where a king is called 'His Majesty,' or Tacitus the prince of political historians.

Antozone. A name proposed by Schönbein to distinguish a peculiar condition of ozone. [OZONE.]

Antozonite. A name given by Schönbein to a fetid variety of Fluor Spar found at Wölsendorf, in the Palatinate.

Antrimolite. A variety of Mesolite, oc-

AORTA

curing in white, silky and fibrous stalactites, in amygdaloid, at Ballintoy, on the north coast of Antrim, in Ireland.

Antrum (Lat.). A cavity in the superior maxillary bone. It is frequently termed *antrum Highmorianum*, from the name of its discoverer, the eminent surgeon, Highmore.

Antrustions; otherwise styled *Fideles* (Faithful) and *Leudes* (Leute, Germ. people). A class of people among the Franks, who were the personal vassals or dependents of the kings and counts. They were not dependent on them by reason of holding lands by their grant, but rather, in consequence of being such dependents, were favoured with donations of land, or benefices; which, in process of time, becoming hereditary, assumed the character of fiefs. [FUDAL SYSTEM.] The original word from which antrustion is derived was undoubtedly the same with that from which our word *trust*, confidence, has its descent.

Anubis. In Mythology, an Egyptian deity, identified by the Greeks with Hermes. In Egyptian painting and sculpture he is represented as a man with the head of a dog, whence Virgil (*Æneid*, viii. 698) speaks of Anubis as *laturator*.

Anus. The excrementary orifice of the alimentary canal, which sometimes opens directly on the exterior surface of the animal, as in most Mammals; sometimes into a cavity common to it with the outlets of the urinary and genital organs, called the cloaca, as in most oviparous Vertebrates; sometimes into the respiratory cavity, as in most Mollusks. In Entomology, it signifies the two last segments of the abdomen, and includes the podex, hypopygium, culus, ovipositor, and appendices. In most of the Acrites there is but one orifice to the alimentary cavity, which thus combines the functions of mouth and anus.

Anvil (Anglo-Sax. *sufil*). A mass of iron on which a smith works the piece of iron he is operating upon. The generality of anvils are made with a square block of iron in the centre, to which a strong projecting and pointed piece of steel, called the beak iron, is welded; the quarter, with a hole for various tools, and the feet are attached; the whole of the smooth face on the top is formed of steel. At the present day, the whole of the upper part of an anvil is worked out of one piece of wrought iron, and the lower part, or the feet, is of another; and the best anvils are made to incline inwards from the outer face on both sides, in order to resist the tendency of the iron to spread laterally under the series of blows it receives.

Aorist (Gr. *ἀόριστος*, indefinite). In Grammar, that inflexion of the verb which leaves the time of the action denoted uncertain.

Aorta (Gr. *ἀσπρί*). The great arterial trunk which issues from the left ventricle of the heart. After death it is found empty. It is single in Mammals and Birds; double in most Reptiles, and in the Cephalopods; triple in the Crustaceans.

APAGYNOUS

Apagynous (Gr. ἀπαγ, *once*, and γυνή, *a female*). When a plant fructifies but once, perishing immediately after it flowers. It is the same as monocarpic, and nearly the same as annual; only that, like the latter term, it includes such plants as the American agave, which live many years before they fructify.

Apalus. A Linnæan genus of Coleopterous insects, having the antennæ filiform; the palpi equal and filiform; the maxillæ horny and one-toothed; the labium membranaceous, truncate, and entire.

Apanage or **Appanage** (Low Lat. appanagium, *an allowance for bread*, i.e. panis). In the Feudal Law, an allowance to younger branches of a sovereign house out of the revenues of the country; generally together with a grant of public domains. A district with the right of ruling it, when thus conferred, is termed *paragium*. An apanage, in ordinary cases, descends to the children of the prince who enjoys it.

Apatelite. A mineral resembling Copiapite, found in small friable nodules of a clear yellow colour, disseminated in an argillaceous bed at Meudon and Auteuil, in France.

Apatite (Gr. ἀπατή, *I deceive*; from the fallacious resemblance it bears to other minerals). Native Phosphate of Lime. When crystallized it occurs in six-sided prisms, usually of a green or greenish colour. The amorphous varieties are used for manure, and the massive kinds found in Spain, at Logrosan in Estremadura, furnish a building-stone. Apatite usually occurs in crystalline rocks, but it is also found in granular limestone and sometimes in serpentine. In the United Kingdom it is met with in Devonshire, Cornwall, Cumberland, and Aberdeenshire; in Ireland in the granite of co. Antrim, and in limestone at Killiney Hill. The chief foreign localities are Saxony, Bohemia, St. Gotthard, the Tyrol, Norway, Spain, Portugal, France, Bucharia in Asia, N. America, &c. It frequently contains fluoride of calcium. [PHOSPHORITE.]

Apatoid. A mineral found in very minute quantity in certain meteorites, in the form of small yellow transparent grains. The name Apatoid has reference to its external resemblance to Apatite; but it does not contain phosphoric acid.

Apaturia (Gr. ἀπαυρία). An Athenian festival, celebrated in the month Pyanepsion, by the Ionian cities, except Colophon and Ephesus. The name is derived from ἀ=αἶμα and παρῖα, and so expressed the meeting of a people according to their Phratriæ.

Apaumé (Fr. paume, *the palm of the hand*). In Heraldry, a hand opened so that the whole palm is seen, with the thumb and fingers extended, as shown on the arms of baronets.

Ape (Anglo-Sax. apa). In the Zoological sense, is restricted to those higher organised species of the Linnæan *Simia* which are destitute of a tail. They are included in the modern subgenera *Troglodytes*, *Pithecius*, and *Hylapates*, or the chimpanzees, oranges, and gibbons.

APHELION

Apelleans, or **Apellites**. In Ecclesiastical History, heretics of the second century, said to have entertained the doctrine that the body of Christ perished at his ascension.

Apellous (Gr. ἀ, *priv.*, and Lat. pellis, *skin*). Destitute of skin.

Apennines. This principal spur of the higher Alps runs through and forms the backbone of Italy, having a total length of about 800 miles, and rising in the southern part to an elevation of more than nine thousand feet. Two of the great volcanic mountains of Europe, Vesuvius and Etna, belong to this chain, and recent volcanic action is traceable in many parts of the district around. The chain of the Dalmatian coast and Albania, on the other side of the Adriatic, extends into Greece, always parallel to the Apennines, and the two thus form a part of one great link connecting the Alps by a series of broken links with the Taurus chain, and so with the Asiatic mountain systems. The direction of the Apennines is on the whole south-east. The chain is narrow and continuous for the most part, but has some fine valleys and gorges, especially in the south.

Apetalous (Gr. ἀ, *priv.*, πέταλον, *a petal*). When a flower has a calyx only, and no corolla; sometimes extended to cases in which there is neither calyx nor corolla; thus, the apetalous plants of Jussieu are either destitute of a corolla only, or of all floral envelopes.

Apex (Lat.). The summit or highest point of anything. Thus, the apex of a cone, of a pyramid, &c.

Aphanipterous, **Aphaniptera** (Gr. ἀφανής, *unseen*, and πτερόν, *wing*). The name of an order of Apterous Haustellate insects, having rudimental elytra or wings in the perfect state, and undergoing a metamorphosis, resembling that of the *Tipulide*, or crane-flies. The common flea (*Pulex irritans*, Lin.) may be regarded as the type of this order. The female flea (*Pulex irritans*, Lin.) deposits a dozen eggs, of a white colour and rather viscous texture, from which proceed little apodal maggots, which are very active in their motions, winding themselves in a serpentine manner through the substance in which they may be deposited: the head of the larva is protected by a firm skin, and bears two small antennæ, but no eyes; the body consists of thirteen segments, bearing little tufts of hair, and the last is armed with a pair of hooklets: the mouth presents some small movable instruments with which the maggot hauls itself along. After having passed twelve days under this form, the larva spins itself a little silken cocoon, in which it passes into the pupa state, and in about twelve days more emerges a perfect flea; this metamorphosis distinguishes the flea and chigoe from other blood-sucking parasitic Apterous insects; and they are further distinguished by the number of segments into which their body is divided, and their pentamerous, or five-jointed, tarsi.

Apellion (Gr. ἀπό, *from*, and ἥλιος, *the sun*). In Astronomy, is that point of a planet's orbit which is at the greatest distance from

APHERESIS

the sun. It is opposed to perihelion, which signifies the point of the orbit nearest the sun. The aphelion and perihelion of an orbit are consequently the two extremities of its greater axis. In consequence of the mutual attractions of the planets, the positions and figures of their orbits are constantly undergoing a slow variation. The aphelia gradually shift their places on the planes of the orbits; and it is remarkable that these motions are direct, or eastward, in the case of all the planets excepting Venus, the aphelion of whose orbit, when referred to the fixed stars, moves westward at the rate of about 4 seconds annually. Of the old planets, Saturn is that whose aphelion undergoes the greatest annual variation; it amounts to about 18 seconds of a degree. [PERIHELION; PLANET.]

Apheresis or **Aphaeresis** (Gr. ἀφαίρεσις, from ἀφαίρω, *I take away*). In Grammar, a figure by which a letter or a syllable is cut off from the beginning of a word; as in the common abbreviation, 'tis, for 'it is.'

Aphides. A family of emipterous insects, commonly called 'plant-lice,' inhabiting trees and plants, and living on their juices; remarkable for the anal saccharine secretion referred to in ANAL GLANDS, but more especially for a peculiarity of their generative economy, particularly described by Bonnet, and which consists in the first fecundation of the female influencing not merely the ova immediately developed thereafter, but those of the females resulting from that development, even to the ninth generation, which are successively impregnated and productive without any intercourse with the male insects. Certain Coleopterous insects, which prey upon the Aphides, are termed Aphidiphagi and Aphidivora (φάγω, *I eat*; voro, *I devour*).

Aphlaston. [POOF.]

Aphlogistic (Gr. ἀφλογιστος). Without flame or fire.

Aphlogistic Lamp. A lamp with a glowing wick, the combustion of which goes on without flame.

Aphony (Gr. ἀφωνία, from ἀ, priv., and φωνή, *voice*). Loss of voice.

Aphorism (Gr. ἀφορισμός, from ἀφορίζω, *to define, or limit*). A term chiefly used in Law and Medicine, but occasionally also in Moral Philosophy, &c., to denote a comprehensive maxim or principle expressed in a few words.

Aphrite (Gr. ἀφρός, *froth*). A nearly pure carbonate of lime, sometimes occurring in a very soft, loose and friable state, in beds and veins in the older rocks.

Aphrizite (Gr. ἀφριζω, *to froth*). A sub-variety of Tourmaline occurring in small, brilliant, black crystals in decomposed Felspar, at St. Just in Cornwall, and in the Harz. It froths under the blowpipe.

Aphrodisiac (Gr. Ἀφροδισια, *Venus*). That which incites to venery.

Aphrodite (Gr.). In Greek Mythology, a name given to the Goddess of Love, who was identified with the Latin Venus. According to

APIOCRINITES

the Hesiodic Theogony (197), she sprang from the sea-foam, Ἀφρός, after the mutilation of Ouranos by Kronos, and so received her name. In the *Iliad* and *Odyssey* she is the daughter of Zeus and Dione, the wife of Hephaestus, and the paramour of Ares. In the so-called Homeric hymns she is the mother of Æneas by Anchises.

APHRODITE. A soft and earthy mineral of a white or yellowish colour, and with a waxy lustre, found at Langbanshytta in Sweden. It is a hydrated silicate of magnesia, and resembles Meerschaum.

APHRODITE. This classical name was applied by Linneus to a beautiful genus of Anellidans adorned with resplendent silky hairs and bristles, of which the seamouse (*Aphrodita aculeata*, Lin.) of our coasts is an example.

Aphroditidæ. The name of the family of Anellidans, of which the seamouse, or *Aphrodita aculeata*, is the type.

Aphrosiderite (Gr. ἀφρός, *froth*, and σίδηρος, *iron*). A ferruginous Ripidolite occurring in fine scaly grains in Nassau and Weilburg.

Aphthæ (Gr. ἀφθα). In Medicine, the thrush; small round superficial ulcers, seated principally in the extremity of the excretory vessels, salivary glands, &c.

Aphthonite (Gr. ἀφθονος, *abundant*). A mineral resembling an argenteiferous Grey Copper Ore. It occurs massive, of a steel-grey colour, at Wärmkog, in Wermland.

Aphyllanthææ. A small division of the Juncaceous order of Endogens, comprehending the genus *Aphyllanthos* from the south of Europe, with *Calcestasia* and *Dasyppogon* from New Holland.

Aphyllous (Gr. ἀφυλλος). Leafless. The term is, however, sometimes applied to plants in which the leaves are present, but so small as not to look so much like leaves as mere scales. Plants are also called leafless in which, although scales of a considerable size are present, there are no true green leaves: of this description are *Monotropa*, *Orobanchæ*, *Pyrola aphylla*, &c.

Apiaceæ (Lat. apium, *parsley*). One of the names of the natural order *Umbellifera*, constructed with more resemblance to the plan upon which the names of other natural orders are formed in Botany than that of *Umbellifera*.

Apiculate (Lat. apex, *a sharp point*). When a leaf or any other part is suddenly terminated by a distinct point.

Apidæ (Lat. apis, *a bee*). One of the varieties resulting from the modern division of the Linnæan genus *Apis*, including those species which are distinguished by the length of the terminal parts of the inferior organs of the mouth, which constitute a proboscis.

Apine. A gelatinous substance (distinguished by affording a blood-red colour with solution of sulphate of iron), obtained from parsley (*Apium petroselinum*).

Apiocrinites (Gr. ἄπιον, *a pear*; ἄπρον, *a*

bily). Pear Encrinite. [ENCARINITE.] The name of a sub-genus of fossil Encrinites, in which the body is formed of separate pieces articulated with the stem, and supporting the rays by similar articulations, in consequence of which the stem is rounded and dilated into a pyriform figure at its upper part.

Apion. A genus of minute Coleopterous insects of the weevil family (*Curculionidae*); very numerous in species, distinguishable by their elegant pear-shaped form, protruded snout, and straight antennæ.

Apis. In Egyptian Mythology, a bull supposed to be the representative of the god Apis. This fact was held to be ascertained by the occurrence of certain signs in the body of the animal, which are specified by Herodotus, iii. 28. The bull was then consecrated, and received the highest worship. It was not suffered to live more than twenty-five years; and its death was followed by a solemn burial and a general mourning, until a new calf, with the requisite signs, was discovered. By the Greeks this god was called Epaphus, and was said to be the son of Io. The slaughter of Apis by Cambyces was assigned as the cause of his madness. (Herod. iii. 27.)

Apis (Lat. a bee). The Linnæan genus, now subdivided into different families, is thus characterised: mouth horny; jaw and lip membranaceous at the tip; tongue inflected; feelers four, unequal, filiform; antennæ short, filiform, those of the female subclavate; wings flat; sting of the females and neuters pungent, and concealed in the abdomen.

The insects of this extensive genus live some of them in large societies, and some are solitary; their food is the nectar of flowers, honey, and ripe fruit; the larva is soft and without feet; the pupa resembles the perfect insect.

The characters of the Linnæan genus are applicable to a variety of forms, now the types of numerous subgenera, included by Latreille in a family of Aculeate Hymenopterous insects, under the term *Anthophila*, or *Melilifera*. The habits of each of the subgenera of this family are replete with interest, arising from their social economy, and the separation of the individuals into three sexual modifications, viz., the prolific females, or queens; the unprolific females, or workers; and the males, or drones. The policy of the hive-bee (*Apis mellifica*, Lin.) has been studied with so much diligence and detail, that we penetrate this mystery of nature with astonishment, and often feel inclined to regard what Huber relates as fabulous. Nevertheless, the highly interesting observations of this writer, and those especially on which his reputation chiefly rests, have been confirmed by subsequent observers, both scientific entomologists as well as practical apiarians.

The hive-bee is distinguished from all other species of the modern genus *Apis* by having the femora of the posterior pair of legs furnished with a smooth and concave plate on the

outer surface, and fringed with hair, forming a basket adapted for the conveyance of pollen; and in being destitute of spines at the extremity; by the basal joint of the tarsi, in the workers, being of an oblong form, with its inner surface clothed with hairs disposed in transverse rows; by the trophi being of an elongated form, and the maxillary palpi being almost obsolete and consisting of a single joint.

The different individuals of the social *Apis mellifica* more nearly resemble each other in their grade of developement—as regards their locomotive powers, organs of sense, and instinctive endowments—than the ant. No individual among them is without wings; and the industry of the workers, or imperfect females, is less astonishing, at least their tasks are less arduous, than fall to the lot of the Apterous labourers of the ant tribes.

As bees, like most other winged insects, are annuals, or go through the whole essential economy of their existence within the year, the history of a year's existence includes the whole, and we have only to choose the point in the circle at which to commence it.

As some individuals, however, always survive the winter, and begin to breed early in spring, forming a colony which quits the parent stock, we shall begin with this colony, and trace their operations through the year.

The first young swarm in this country is generally sent off in June. The migration seems to depend on want of space in the mother hive, not on an instinctive desire of change on the part of the brood; for if there be space for the operations of the increasing community, bees will not naturally swarm; and skilful apiarians sometimes take advantage of this circumstance, and, by making successive additions to the hive, retain the whole year's increase in the same building. The swarm consists in general of about six or seven thousand individuals, of which about one-thirtieth part are males, the rest females; and of these, one only, for the most part, is prolific, and she is called the queen. Her body is longer than that of either the drone or worker; her colours are brighter and purer, and generally of a darker shade; the transverse bands across the abdomen are of a deeper and brighter yellow, and are sometimes orange; the head is smaller than that of the unprolific female, and the tongue is shorter and more slender; her mandibles are notched, and her sting is curved; but the most obvious distinctive character is the proportional length of the abdominal segment of the body which lodges the generative apparatus, and which is of an elongate conical form, tapering rather sharply to the anus. The male bee is readily distinguished by the short and thick form of his body, which is obtuse at each extremity. He has no sting. The workers, like the queen, are armed with a sting, but it is straight, and proportionally larger and stronger. The workers are essentially females in their internal structure, but their growth is arrested before

arriving at the period when the full development of the sexual system takes place, and they consequently are smaller than either the queen or the drones; and their colours are less bright. According to Huber, there are two varieties of labourers, one of a larger size, which he calls 'abeilles cirières,' or makers of wax; the other, or smaller variety, he terms 'abeilles nourrices,' or nurse-bees, whose crop or first stomach is not capable of the distension requisite for collecting honey, but whose office is to build the combs and cells after the foundation has been laid by the cirières, and to feed the larvæ.

It is also stated there are two kinds of drones; one not larger than the workers, the other as above described. And Huber has described another variety of the inmates of the hive, which he terms 'black bees,' and which are supposed to be the superannuated workers.

The swarm, thus composed, commonly leaves the hive in the heat of the day, and often immediately after a shower. It is supposed that the queen takes the lead, and she ever afterwards exercises an inscrutable influence over all their operations. Perhaps a stronger proof that instincts do not necessarily depend on physical conformation is not afforded by any phenomenon in natural history, than by the effects which the loss or death of the queen produces on the labourers. This event does not deprive them of any organ, or paralyse any limb; yet, the moment they are conscious of her loss, all their labours are interrupted and forsaken, and, unless another queen be provided, they join another hive, or perish from inanition.

The flight of the swarm is directed to some neighbouring fixed place, and wherever the stand is made they all forthwith repair to it. In the wild state, the cavity of an old tree is commonly chosen; and this, with a seeming prudence and foresight which cannot be sufficiently admired. The first care of the bees is to cleanse it from dust and rubbish, and to gnaw off with their mandibles any asperities or projections which might interfere with the future construction of the comb. In the state of domestication in which the hive-bee is usually preserved in this country, the practice of the above instinctive actions is rendered unnecessary, by the reception of the swarm into neat artificial hives. Yet this modification of their habits, and many other interferences to which they are subject, have had no effect in inducing any varieties in the organisation of the bee, nor any change in those instinctive actions which the care of man has not rendered indispensable. The consideration of this curious exception to the ordinary consequences of domestication, and of the conditions on which the circumscribed limits of variation in the bee depend, would lead us far beyond the extent allotted to the present subject; but it is an inquiry full of interest in relation to the recondite laws which govern the variation of animals from their specific standard.

In the wild state, the young colony at first

return occasionally to the parent establishment for supplies of provision; and the domesticated bees always fill their crops with honey before they leave the hive. The wax is a peculiar secretion from the working bee; and having the materials, therefore, within themselves, they immediately begin to form the comb.

Before describing the many-chambered nursery and storehouse which our bees are about to prepare, a few words are necessary regarding the material of which it is constructed.

The formation of the wax is a very singular and complex operation. Huber says, 'The wax-makers, having taken a due portion of honey or sugar, from either of which wax can be elaborated, suspend themselves to each other, the claws of the fore legs of the lowermost being attached to those of the hind pair of the uppermost, and form themselves into a cluster, the exterior layer of which looks like a kind of curtain. This cluster consists of a series of festoons or garlands, which cross each other in all directions, and in which most of the bees turn their back upon the observer: the curtain has no other motion than what it receives from the interior layers, the fluctuations of which are communicated to it. All this time the nurse-bees preserve their wonted activity, and pursue their usual employments. The wax-makers remain immovable for about twenty-four hours, during which period the formation of wax takes place, and thin laminae of this material may be generally perceived under their abdomen. One of these bees is now seen to detach itself from one of the central garlands of the cluster, to make a way amongst its companions to the middle of the vault or top of the hive, and by turning itself round to form a kind of void, in which it can move itself freely. It then suspends itself to the centre of the space which it has cleared, the diameter of which is about an inch. It next seizes one of the laminae of wax with a pincer formed by the posterior metatarsus and tibia, and drawing it from beneath the abdominal segment, one of the anterior legs takes it with its claws and carries it to the mouth.'

The wax has, perhaps, the nearest analogy to the sebaceous secretion of the integument than to any other animal secretion: it is formed beneath the scales on the under side of the abdomen, and, when accumulated there, seems to irritate the part, for the bee may then be observed wagging her abdomen, and running round, or to and fro, as if endeavouring to shake out the little scales; and she is generally followed by one or two other bees which have been attracted by her movements, and are ready to seize upon the plates of wax as they fall. How the bees mould the scales into the walls of the cells is not yet exactly understood. Some have supposed that they bite pieces off and join them together; but the smooth and uniform surface of the cell shows that some other operation must take place: besides, the wall of the cell is sometimes thicker than a

scale of wax. We must, therefore, suppose that the bees have the power of applying some dissolving or softening menstuum to the wax scales, by which they are enabled to knead and blend them into a ductile paste. And when we remember that the secretion of the salivary tubes of insects is generally alkaline, and that wax may be softened by alkali, it has been naturally supposed that it is by this means that the wax-scales are brought into a workable state. Reaumur, indeed, observed a frothy substance exuding from the mouth of a bee while working at a cell, which was applied to the proper place by the nimble tongue, and then kneaded in by the mandibles; and Huber has described the process very circumstantially: he says that the bee holds the lamina of wax with its claws vertically—the tongue rolled up serving for a support—and by elevating or depressing it at will causes the whole of its circumference to be exposed to the action of the mandibles, so that the margin is soon gnawed into pieces, which drop, as they are detached, into the double cavity, bordered with hairs, of the mandibles. These fragments, pressed by others newly separated, fall on one side of the mouth, and issue from it in the form of a very narrow riband. They are then presented to the tongue, which impregnates them with a frothy liquor. During this operation the tongue assumes all sorts of forms: sometimes it is flattened like a spatula; then like a trowel, which applies itself to the riband of wax; at other times it resembles a pencil, terminating in a point. After having moistened the whole of the riband, the tongue pushes it so as to make it re-enter the mandibles, but in an opposite direction, where it is worked up anew. The liquor mixed with the wax communicates to it a whiteness and opacity which it had not before, and doubtless gives it that ductility and tenacity which it possesses in its perfect state.

Bees commonly begin at the top or roof of their chamber, and build downwards, at first working irregularly, and as it were pasting over the surface, and then building horizontal cells of a more perfect form. These at length become so numerous, that they extend downwards in the form of a vertical wall; other congeries of cells are formed in succession, until the whole comb assumes the form of a series of perpendicular plates or partitions. Each plate consists of a double set of cells, the bottoms of which are applied to each other and form the partition between each set. The plates are not always regular, and the irregularities which may be observed are not always necessary adaptations to a peculiar form of the cavity in which they are built. The cells are not all of the same size, but a sufficient number of a given depth are reserved for receiving the eggs, and which are necessarily adapted to the size of the future maggot: the smaller or shallower cells are those in which the honey is stored. The breeding and store cells are placed horizontally, but the mouth of the cell is sometimes a little raised—the better to

retain the honey. The interspace between the vertical combs is generally about half an inch: these streets, as they may be termed, in this city of industry, being just wide enough to allow two bees busied upon the opposite cells to pass without incommoding each other. In addition to these interspaces, the combs are perforated in various places, so as to allow a passage for the bees from one street to another, thus saving them much time.

The shape of each cell is not, as might have been expected, cylindrical, or that which seems best adapted to the form of the maggot, or even of the constructor bee; but it is hexagonal—the only form which allows the cell to be of the largest size in proportion to the quantity of matter employed, and at the same time to be so disposed as to occupy in the hive the least possible space. The form of the base of each cell, which is in apposition with the one on the opposite side, is also such as to gain greater strength, and more capacity, with less expenditure of wax; the latter consideration being one of great importance to bees, which do not secrete a very large quantity of this material; and the most profound mathematicians and most skilful geometers have found the solution of the problem, relating to the attainment of the preceding objects, as derived from the infinitesimal calculus, to have a surprising agreement with the actual measure of the different angles formed by the walls of the cell.

There may generally be observed one or more cells, wider and shallower than the rest, placed either on the edge of a comb, or partition; or placed against the mouths of the cells, and projecting beyond the general surface of the comb. These are called the royal cells; but as they are not adapted to the form of the queen, nor ever lined with the silken covering of the chrysalis, the supposition that the queen is bred in them seems improbable.

Having now generally described the comb, we return to the consideration of those instinctive operations by which its several compartments are furnished with their destined contents.

The comb seems at first to be formed entirely for propagation, and, indeed, to be essentially related to that function; for if the workers lose their queen, they make no combs; and the reception of honey is, therefore, its secondary use. Wasps and hornets make combs, although they collect no honey.

As soon as the young colony has prepared a few combs the female begins to exclude her eggs. The first that she lays produce the imperfect females, or workers; the subsequent ones produce the males, and, perhaps, the fertile females, or queens. The eggs are deposited at the bottom of the cells, often before these are half completed; they adhere generally by one end to the cell. In about five days the little maggot is hatched, and is seen lying at the bottom of the cell, coiled up in a transparent fluid.

Now begins the additional employment of the

labourers, that of feeding and nursing the young maggots; for this purpose new materials must be collected abroad, and brought into the hive.

At first the bees of a young colony fly out singly, and afterwards collectively. They direct their flight generally in a straight line, or the nearest way to the destined object, and often travel to great distances from the hive. In summer time they may be seen almost every where where flowers bloom. In April and May they are abroad the whole day; but in the hot months they venture out less frequently generally in the morning and evening, at which times it is more easy for them to form the pellets of the pollen, the grains of which adhere together less strongly during the heat of noon-day.

Bees do not like wet weather; yet it perhaps less the presence of rain, than the changes in the degree of light, which deters them from venturing abroad at this time: for they possess large and complex organs of sight, and when clouds collect quickly over the clear sky, they are seen to hurry back in great numbers to the hive; while if the sky be uniformly overcast, it is not merely a shower of rain that will drive them back: many of the actions of the bee prove, on the contrary, how essential moisture is for them. The bee does not take honey indiscriminately from every flower, in the meadows they may be seen generally upon the *Orchideæ*, *Polygoniæ*, *Caryophyllaceæ*, but seldom, if ever, upon the *Ranunculaceæ*, perhaps on account of some poisonous quality. The oleander (*Nerium oleander*, L.), which yields poisonous honey fatal to thousands of flies, is carefully avoided by bees; and the crown imperial (*Fritillaria imperialis*, L.), the white nectaries of which are so conspicuous, tempts in vain the passing bee. They are, however, extraordinarily active in spring at the blossoming of the *Amentaceæ*, *Rosaceæ* (especially the dog-rose), and the balsamic lilies, *Primulaceæ*, &c.; and are, above all, allured by the innumerable flowers of the lime (especially *Tilia parvifolia*), and their hum may be heard among the branches at some distance. The finest flavoured and most delicate honey is collected from aromatic plants; and it is therefore always advisable to have large beds of borage, mignionette, lemon thyme, and sage in the neighbourhood of beehives. Those flowers which yield a nectar innocuous to the bees themselves, but possessing poisonous qualities when taken by man, are sometimes frequented by bees, and the honey derived from them acts like a poison. The description by Xenophon of the intoxicating or maddening honey, which so violently affected a number of the ten thousand Greek soldiers in his celebrated retreat, has been confirmed by the observations of Tournefort; and Dr. Barton, in his account of the poisonous honey collected from the *Kalmia latifolia* by the bees in Pennsylvania, justly observes, that there is more of poetry than philosophy in the following lines of Pope:—

VOL. I.

In the nice bee what sense so subtly true,
From poisonous herbs extracts the healing dew.

The honey which is swallowed by the bee passes into the crop, where it is accumulated as in a reservoir, and upon the return of the bee to the hive is regurgitated into a honey cell. If any honey had been previously accumulated there, the bee breaks through the firm cream-like crust which always forms upon the exposed surface of the honey; and it is this crust which maintains the honey in the horizontal cells.

The collection of the farina, or pollen, of flowers is a great object of the industry of bees. In large flowers, as the tulip, the bee dives in; and if the pollen receptacle, or anther, be not burst, she bites it open, and comes out singularly disguised, being covered over entirely with the fertilising dust, which adheres readily to the fringed hairs of her body and legs.

Aristotle, who was well acquainted with much that is interesting in the economy of the bee, was the first to observe that a bee, during each single excursion from the hive, limits her visits to one species of flower. Modern naturalists have confirmed the general accuracy of this statement, and have noticed that the pollen with which a bee comes home laden is always of the same colour. The necessity of this instinct arises out of the operation which the pollen first undergoes when collected by the bee. She rakes it out with incredible quickness by means of the first pair of legs; then passes it to the middle pair, which transfer it to the hind legs, by which it is wrought up into little pellets. Now, if the pollen were taken indiscriminately from different flowers, it is probable that the grains, being heterogeneous, would not cohere so effectually. Certain it is, that bees enter the hive, some with yellow pellets, others with orange, pink, white, or even green-coloured ones; but they are never observed to be party-coloured. Through this instinct, another important end is gained, in relation to the impregnation of flowers; the production of hybrid plants by the application of the pollen of one species to the stigma of another is avoided—while those flowers are more effectually fertilised which require the aid of insects for that purpose.

When a pollen-laden bee arrives at the hive, she generally walks or stands upon the comb beating her wings, and three or four of her fellow-citizens assist in lightening her of her load; or the laden bee puts her two hind legs into a cell, and with the intermediate pair, or the extremity of the abdomen, brushes off the pellets. These are then kneaded into a paste at the bottom of the cell; and several cells are thus filled with the packed and softened pollen, which is called bee-bread.

Besides the honey and farina, bees also collect a peculiar substance, like gum-resin, which was called 'propolis' by Pliny; and this they obtain principally from the balsamic buds of the horse-chestnut, birch, and poplar, especially the *Populus balsamifera*, L. The

propolis is soft, red, will pull out in a thread, and is aromatic. It is employed in the hive, not only in finishing the combs, but also in stopping up every chink or orifice by which cold, wet, or any enemy can enter. Like the pellets of pollen, it is carried on the posterior tibiae, but the are lenticular. Having thus traced the operations of the working bees relating to the collection of the substances required in the economy of the hive, we shall now return to the larvæ, which are the immediate objects of all this industry.

The bees may be readily detected feeding the young maggot, which opens its lateral jaws to receive the bee-bread, and swallows it. The well-fed maggot soon grows too large for its tough outer skin, and accordingly casts it; when its bulk has increased so that it fills its cell, it then requires no more food, and is ready to be enclosed for the chrysalis state. The last care of the foster-parents is to cover over the mouth of the cell with a substance of a light brown colour, apparently a mixture of wax and farina. This takes place generally four days after the larva was excluded from the egg. The enclosed larva now begins to line the cell, and covering of the aperture before mentioned, with a silk, which it spins from glandular tubes, similar to those of the silkworm. When the first three segments of the trunk, to which the locomotive organs of the perfect insect are attached, begin to be enlarged, the last larva-skin splits along the back, and is pushed off from the head backwards, and deposited at the bottom of the cell, and it then becomes a chrysalis. Now the wonderful changes take place, partly by a formation of new organs, partly by a development of pre-existing ones, which end at last in the completion of the perfect bee.

Mr. Hunter ascertained the duration of the pupa state of the bee to be, in one instance, thirteen days and twelve hours exactly; making the period of immature life, from the first deposition of the egg, to be twenty-two days and a half—a remarkably brief time for the completion of the metamorphoses, as compared with that in which the corresponding changes are effected in other metabolan insects. When the bee first comes forth it is of a greyish colour, but soon assumes the ordinary brown tints.

When the season of oviposition and the rearing of the larvæ is over, then the business of collecting honey seriously begins; and when the last chrysalis of the season has disclosed its imago, the deserted cell is immediately filled with honey, and covered over with wax, to serve as a store for winter.

In the month of August it is supposed that the prolific female, which is to produce the swarms of the following year, is impregnated. This act takes place in the air. The queen, being preceded by the drones, traverses the exterior of the hive, and suddenly rises aloft in the air, wheeling upwards in large circles, until she is out of sight. The male, unable

to extricate the intromitted parts, generally perishes. The rest of this unhappy sex share a similar fate, and meet a violent death from the jaws of the unprolific females. It would seem as if the drones were conscious of their danger at this season, for they do not loiter as usual at the mouth of the hive, but hurry in or out. However, they are attacked, by one, two, or three workers at a time, who do not sting them, as Huber asserts, but pinch them and pull them about, as if to wear them out. From this instinctive and indiscriminate slaughter of the males, we may infer that the impregnation of the queen has taken place before the setting in of the winter season; and that the ova, the development of which is retarded during the indolent state in which bees pass through the cold months, are in a condition to be developed and produce the larvæ at the approach of spring. Yet, although on the setting in of the cold weather the bees remain very quiet, they are not torpid, as is the case with most other insects. They cluster as close together as the comb will permit, and have the faculty of generating a degree of heat superior to that of the external atmosphere.

Mr. Hunter found, during an evening in July, when the temperature of the atmosphere was 54°, that of the interior of a hive full of bees 82°; and in December, the external atmosphere being 35°, the bees preserved a temperature of 73°; and, what is, at this season, extremely rare in the lower animals, they maintain their digestive powers, and subsist on the produce of the summer and autumn. Accordingly, they are ready to take advantage of any fine and mild day, and may be seen then flying abroad and appearing to enjoy it. They void their excrements at this time, for they are insects of singular cleanliness and propriety; and when purposely confined in the hive, with abundance of food, they have been known to fall a sacrifice to this instinctive repugnance to defile the hive.

The continuance of the digestive actions during the winter influences the condition of the oviducts in the queen, and the impregnated ova begin early to expand, and are ready for exclusion in the month of March. This makes the bee the earliest breeder amongst the insects of this country. The labourers now resume their accustomed duties, and, as the season is too early for collecting the provision of the maggot abroad, the store of bee-bread, laid up in the preceding year, comes into use for the sustenance of the larvæ, which are about to form the first swarm. As soon, however, as the flowers begin to blow, the bees fly forth to gather fresh pollen, propolis, and honey, and the labours of the year recommence.

It appears to be the presence of the larvæ destined to become perfect females which stimulates the old queen to leave the hive. After repeated attempts to penetrate their cells, and destroy her royal progeny, she becomes infuriated, communicates her agitation to a portion of her subjects, which, together

with her, rush out of the hive, and seek a new domicile. It is stated that in every instance the old queen leads the first swarm; the labourers that remain pay particular attention to the royal larvæ that remain; and these, as they are successively excluded, lead away fresh swarms, if the hive be not sufficiently enlarged. Each swarm contains, not only the recently hatched young bees, but also a portion of the old inhabitants. Some assert that the queen which leads each swarm is impregnated soon after the new colony is settled; and, as this may take place early in the summer, she begins to oviposit the same year. The number of ova which are fertilised by a single coupling is prodigious: Huber calculates that the queen lays 12,000 eggs in two months; while, according to Reaumur, she oviposits at the rate of 200 a day. The duration of life of the different individuals of the hive varies: that of the male bee is not more than two or three months; there is more doubt respecting the longevity of the workers, but it is probable that it does not extend much beyond a year. The term of the queen's existence has been stated to be prolonged for five years; but this is rendered improbable by the fact that all insects of the same species have nearly the same duration of existence allotted to them.

The true honey-bee (*Apis mellifica*, L.) was originally limited in its geographical range to the Old World, whence it has been transported to America, and other countries where European colonies have been established, and where it is now acclimated. The distinguished entomologist Latreille, on whose authority we state this fact (*Règne Animal*, tom. v. p. 365.), is even of opinion that the honey-bee of the south and east of Europe, as well as that of Egypt, differs specifically from the *Apis mellifica* of Western Europe. [HIVE; HONEY.]

Apistes (Gr. ἀπίστος, treacherous). A genus of Acanthopterygians fishes, notable for a strong suborbital spine, with which they are apt to inflict severe wounds when incautiously handled.

Apjohnite. A kind of manganesian alum found in acicular crystals with a silky lustre, like Asbestos, near Lagoa Bay in S. Africa.

The name Apjohnite has also been given to a metallic ore of a brownish-lead colour, found in Ireland, mixed with Iron Pyrites. It is composed of bisulphide of iron, sulphide of lead, and sulphide of zinc.

Aplanatic Lens (Gr. ἀ, without, and πλάνη, deviation). In Optics, a lens such that rays parallel to its axis, or rays diverging from a point in its axis, after passing through it and suffering refraction at its surfaces, converge to a single point, or the true focus. In order therefore to be aplanatic, the lens must not only have the true geometrical figure necessary to destroy aberration, but must also be constructed of different media, so as to correct the effects of the unequal refrangibility of the different rays, that is to say, it must be achromatic. Neither of these conditions can be

accurately fulfilled in practice; the object aimed at is therefore to give the lens such a form that, with a given index of refraction, the aberration shall be the least possible. [ABERRATION; ACHROMATISM.]

Aplome (Gr. ἀπλός, simple). A variety of Garnet. The name has reference to the derivation of the rhombic dodecahedron (in which form it commonly occurs), from the cube, by one of the simplest laws of decrement.

Apletaxis (Gr. ἀπλός, single, and τάξις, a series). To this genus of *Compositæ*, which is found in the Alpine and temperate parts of the Himalaya, belongs the costus of the ancients, *A. Lappa*, which has also been described under the name of *Aucklandia Costus*. This is found on the mountain slopes of the Kashmir valley, and is a gregarious herb, with thick perennial aromatic roots, a tall annual stem, lyrate-pinnatifid leaves, and purple flowerheads. Large quantities of the roots, said to amount to 200,000 lbs. weight, are annually collected for exportation. The root is used by the Chinese as an aphrodisiac, and for incense in their temples.

Aplustræ. [POOR.]

Aplysia (Gr. ἀπλυσία, uncleanness). A genus of Tectibranchiata Gasteropoda, well known to the ancients under the name of *Lepus marinus*, or sea hare, from a resemblance which the long tentacles give it to the head of the hare. By Aristotle, the name was applied to certain zoophytes, but was arbitrarily transferred by Linnaeus to the molluscan animals now known under this denomination.

Apocalypses (Gr. ἀποκάλυψις). The book of Revelations, the last in the canon of the New Testament. Many conflicting opinions have been entertained as to the authenticity of this book. It was rejected by Luther, but the opinion of the great majority of orthodox critics and divines in modern times has been decidedly in favour of its genuineness. There have, also, been great varieties of opinion as to the person by whom, and the period when, the book was written: but the prevalent opinion is, that it is the work of St. John the Evangelist. See, for a searching examination of this question, Alford's *Greek Testament*, and the authorities there cited. Compare also *National Review*, April 1864, art. 'Apocalypse of St. John.' The phrase 'apocalyptic writings' is frequently used to designate those other portions of the Scriptures which contain prophetic descriptions, under the form of visions, of the future state of the church: such as the book of Daniel; and, among the Apocrypha, the fourth book of Esdras.

Apocarpous (Gr. ἀπό, from, and καρπός, fruit). When the carpels of a flower either do not adhere to each other at all, as in the strawberry, or only by the ovaries, as in *Nigella*. When a carpel is altogether single in a flower, it is considered, for systematic purposes, apocarpous, the supposition being that if another carpel were present it would not adhere to the first.

Apocrenic Acid (Gr. κρήνη, a fountain).

An extractive or brown matter found in some spring waters, and in ordinary vegetable mould. It contains ammonia.

Apocristarius (Gr. ἀποκριτάρης, *I answer*). In Ecclesiastical History, one who resided at the Emperor's court in the name of a foreign church or bishop. The office was established by law in the time of Justinian; and the name was at length confined to the papal nuncio who resided at Constantinople.

Apocrypha (Gr. ἀποκρυφα). Properly, things concealed or put out of sight; applied to books, in behalf of which a claim to inspiration has been put forth, but which are supposed to be spurious, and are therefore rejected from the canon of Scripture. One great distinction between the Roman and the Reformed churches is, that the latter reject certain books, admitted by the former on the same footing as those books about which there is no dispute, from the canon of the Old Testament; viz. the third and fourth of Esdras, the book of Tobias, that of Judith, the rest of the book of Esther, that of Wisdom, of Jesus the son of Sirach, Baruch the prophet, the Song of the Three Children, the story of Susanna, of Bel and the Dragon, the Prayer of Manasses, and the first and second Maccabees; reading them, as the sixth Article of the English church declares, for example of life and instruction of manners, but not applying them to establish any doctrine. The English church receives no books into the canon of the Old Testament which were not so received by the Jews; and it appears that the writings thus excluded are not quoted by the authors of the New Testament, nor are admitted into any of the earlier catalogues set forth by the Christian fathers. There exist at the present day various writings purporting to be the Gospels or Epistles of Joseph, of James the Apostle, of St. Paul, an Epistle of Christ himself to king Abgarus, &c.; which are, for the most part, intrinsically absurd; and, having no external evidence or authority in their favour, have never obtained currency in the church. [CANON.]

Apocynaceæ. An extensive natural order of plants, named after *Apocynum*, one of the more common of its genera. A few species are found in cold climates, but by far the larger part are natives of warm or tropical latitudes, in the form of shrubs or trees, or twining plants, some of which are remarkable for their beauty, as various species of *Echites*; others for their poisonous properties, as *Cerbera*, which furnishes the Tanghin poison of Madagascar; while a third set produce bark, having useful bitter and febrifugal properties. The inspissated milk that flows from these plants constitutes their poison; the febrifugal bitter principle is an independent secretion, that becomes useful when it can be separated from the milk. Notwithstanding these dangerous properties, the fruits of some species are eatable, as that of *Carissa*, the cream fruit of Sierra Leone, and some others.

Apode or **Apoda** (Gr. ἀ, priv. and ποῦς,

foot.) Footless. A term applied by Latreille to a section of Saurians or lizards, by Meyer to a family of serpents, and by Opfel to a family of Batrachians; by Linnæus to his first order of fishes which have no ventral fins, and by Cuvier a suborder of Malacopterygia, or soft-finned fishes, is thus designated, comprehending those which are devoid of the ventral fins, or the homologues of the posterior extremities. It is also indicative of those larvæ of insects which have only the soft tubercles or prolegs; and as the skins of the bird of paradise, imported as an article of commerce, were always deprived of the legs, it was for some time believed that the species was naturally without feet, and it was consequently termed *Paradisea apoda*.

Apodictic (Gr. ἀποδεικτικός, *demonstrative*). A philosophical term adopted by Kant from Aristotle, to distinguish judgments which are beyond contradiction from those which are merely empirical.

Apodogynous (Gr. ἀ, priv., γυνῆς, *a foot*, and γυνῆ, *a female*). A name given by Richard to disks which do not adhere to the base of an ovary.

Apodosis (Gr. from ἀποδίδωμι, *to give back*). In Grammar and Rhetoric, the second part of a period. [PROTASIS.]

Apogee (Gr. ἀπό, *from*, and γῆ, *the earth*). Applied, in Astronomy, to the orbit of the moon and the apparent orbits of the sun or planets, to denote the points of those orbits most remote from the earth. It is opposed to perigee, which denotes the point nearest the earth. The apogee of the lunar orbit advances eastward among the stars, and completes a revolution in about nine years.

Apogluic Acid. Oxidised glucic acid.

Apollinarians. In Ecclesiastical History, a sect who denied the humanity of Christ as far as regards the soul, believing its place to be supplied by the *Logos*, or Word of God. Apollinaris, their founder, was a bishop of Laodicea in the latter part of the fourth century: his doctrine was condemned by the council of Constantinople, A.D. 381.

Apollo, or **Phœbus**. In Greek Mythology, the god of Light and Day, represented with very various attributes, all of which may be traced to the early mythical speech on the action of the sun. The Homeric hymn to Apollo contains two poems, the earlier of which relates that his mother, Lêtô, or Latona (whose name may be identified with the Greek *Lethæ*, and the Latin *Letum*), took refuge in Delos, where Apollo was born, and where she promised that he should dwell for ever. The later hymn speaks of him as forsaking Delos, and wandering to Delphi, where he slays the dragon Python, which reappears in Northern Mythology as the serpent Fafrir. Many amours are attributed to Apollo, among the most noted being that with Daphnê (a name identified with the Sanskrit *Dahand* or *Dawn*), which represents her as flying from the god to her father Peneios, the later legend adding that

she was turned into a laurel tree. For a complete analysis of this subject, see Max Müller's *Comparative Mythology in Oxford Essays* for 1856.

Apollo Belvidere. A beautiful statue of Apollo, found, towards the end of the fifteenth century, among the ruins of the ancient Antium. It was purchased by Pope Julius II., who placed it in the Belvidere of the Vatican, whence it takes its name. It is, perhaps, the noblest work of art. The god is standing, about seven feet high, and almost naked. His quiver hangs over his right shoulder; his pallium over his left arm, which is extended; and in his hands are the remains of a bow, out of which he is supposed to have just discharged the arrow that killed the serpent Python. The whole figure has about it an indescribable air of grace, beauty, and majesty.

This *chef-d'œuvre* of Greek sculpture has been supposed by some, but on very slight grounds, to be referred to by Pliny (*Hist. Nat.* xxxvi. 4). The best critics are of opinion that the artist is wholly unknown. This noble statue was conveyed to Paris by Napoleon; but, on the downfall of the latter, it was again restored to the Vatican.

Apollonicon, a chamber organ of vast power, constructed by Messrs. Flight & Robinson, of London, in 1817. It had 1,900 pipes, some of them of immense size, forty-five stops, and was provided with five key-boards and two barrels. The whole of the accessories were on a very complex scale.

Apollyon, A Greek name of the destroyer, and answering to *Abaddon*.

Apologue (Gr. ἀπόλογος). In Literature, a fable or fiction, of which the object is moral. According to some definitions of the Apologue, it is a fable of which the interlocutors or subjects are animals; but this seems an unfounded limitation. [FABLE.]

Apology (Gr. ἀπολογία). In Literature, a defence, or answer to an accusation. The two pieces of Xenophon and Plato, each commonly termed *Apologia*, differ in character: the first being a defence supposed to be pronounced by the philosopher himself; the last, a narrative of his last hours and discourses. Treatises in defence of the Christian religion, in its early period, were denominated *Apologies* by their writers; as those of Justin Martyr, Tertullian, and others, both preserved and lost. The title has been retained by some writers in modern times: as by Robert Barclay, in his *Apology of Quakerism*, by Bishop Watson, in his *Apologies for the Bible* and for Christianity, and more recently by Dr. Newman in his *Apologia pro Vita sua*.

Aponeurotic (ἀπὸ, from, and νεῦρον, nerve). A term used in Anatomy, applied to the flattened membranes, *lamina* or *fascia*, in which the separate fibres of the voluntary muscles are arranged. The involuntary muscles, on the contrary, are densely interlaced at various angles, the layer formed by them

usually circumscribing the wall of a cavity constructed by the muscular fibre.

Apopemptic (Gr. ἀποπemptus, *I send away*). In Poetry, a poem addressed to one departing from his country on a journey. Horace, book i. ode 3, is commonly cited as a noted example. In modern poetry, a finer instance can hardly be found than Schiller's lines addressed to the Duke of Saxe-Weimar on his going to France: 'So bringet nun die letzte volle Schale; &c.

Apophthegm (Gr. ἀποφθέγμα, from φθέγγωμαι, *I speak*). A short and sententious speech or saying. The apophthegms of the ancients are generally sentences expressing some truth of universal application in philosophy, the conduct of life, &c. &c. Such are Plutarch's 'Apophthegmata Laconica,' a collection of the brief and pointed sayings for which the Lacedæmonians were famous.

Apophyge (Gr. ἀποφυγή, *a flying off*). A term used by writers on Architecture to express the hollow connecting the top of the shaft of a column with the fillet immediately above it; and also the similar hollow connecting the bottom of the column with the fillet at the base.

Apophyllic Acid. A product of the oxidation of cotarine.

Apophyllite (Gr. ἀποφυλλίζω, *to exfoliate*). A zeolitic mineral with a lamellar structure, the name of which has reference to the way in which it exfoliates before the blowpipe. It is a hydrated silicate of lime and potash, occurring in square prisms, the solid angles of which are sometimes replaced by triangular or rhombic planes. The colour is white or greyish, often with a tinge of green, yellow, blue, or red; transparent to opaque, brittle, lustre shining or pearly on planes of cleavage. It is found in druse cavities of amygdaloidal rocks at Ratho near Edinburgh; near Raith in Fifeshire; Old Kilpatrick in Dumbartonshire; Taliaker in Inverness-shire; Portrush; Ballintoy, county Antrim; also in Greenland, Iceland, Hindostan, the Tyrol, Harz, Bohemia, Saxony, Siberia, North America, &c.

Apophysis (Gr. ἀπόφυσις). A protuberance, process, or projection. In Anatomy, restricted to processes of the osseous system.

Apoplexy (Gr. ἀπὸ πλῆξ, *stupor from a blow*). A sudden suspension or loss of the powers of sense or motion; the heart continues to act, and respiration is continued, though often with some difficulty.

Aporobranchians, **Aporobranchiata** (Gr. ἀπορία, *I am in want*, and βραγχία, *gills*). A name applied by Latreille to an order of the class Arachnida, characterised by the absence of stigmata or respiratory pores on the surface of the body.

Apesopodin (Gr. ἀπὸ, from, and σπινδα, *putrefaction*). A peculiar crystallised substance obtained from putrid cheese. [LAVOURA.]

Aposiopesis (Gr.). A figure in Rhetoric and Composition, by which a sentence is made to break off abruptly when unfinished either in sense or grammatical construction; so that the

part which was to follow appears to be retained in the mind of the speaker or writer. In writing, the Apostrophe is now often denoted by an horizontal line or break—at the point where the sense is interrupted.

Apostasiaceæ. A very small natural order of plants found in the tropics of India, closely allied to *Orchidaceæ*, from which they differ in having a three-celled ovary and diandrous flowers, the sexes of which are partly free. *Apostasia* is the principal genus.

Apostill. In Literature, a marginal note to a book.

Apostle (Gr. ἀποστόλος). A person sent forth upon any business: hence applied, by way of eminence, to the twelve elect disciples of Christ, who were sent forth by him to convert and baptize all nations. In the first century, the apostles assumed the highest office in the church; and the term apostle during that period was equivalent to bishop in after times. According to Theodoret (y. Birgham, *Antiq.* ii. ii. §1.), the titles of bishop and presbyter were originally applied promiscuously to the same, or second, order in the church.

Apostles' Creed. A confession of faith, supposed anciently to have been drawn up by the apostles themselves, and deriving the title 'Creed' from the word with which it begins in Latin (*credo, I believe*). With respect to its antiquity, it may be affirmed that most of its clauses are quoted by the apostolic father Ignatius; and that the whole, as it now stands in our liturgy, is to be found in the works of St. Ambrose, in the fourth century.

Apostolic Fathers. The writers of the Christian Church, who lived in the apostolic age, or were during any part of their lives contemporary with the apostles. They are five: Clement of Rome, Barnabas, Hermas, Ignatius, and Polycarp; of whom the last suffered martyrdom, A.D. 147. Of these the three first are supposed to be mentioned in the Epistles and Acts; the fourth, according to a prevalent tradition, was the child whom Christ took in his arms, whence he was called Theophorus; and the fifth, who suffered at a very advanced age, seems to be the angel or bishop of Smyrna whom St. John addresses in the Revelations.

Apostrophe (Gr. a turning away). In Rhetoric, a figure of speech by which the orator or writer suddenly breaks off from the previous method of his discourse, and addresses himself in the second person to some person or thing, absent or present. It is not necessarily an address to the absent or dead, although often so defined. An orator, who should suddenly direct his speech to one of the audience, would be employing an apostrophe. It is, like other figures of speech, an imitation of one of the most natural effects of strong emotion. In oratory, the Apostrophe of Demosthenes to the gods, at the end of the *Oratio de Coronâ*, and, in narrative writing, that of Tacitus to the shade of Agricola in his biography of that statesman, may be cited as splendid examples of the use of this figure.

Apothecary (Gr. ἀποθήκη, a storehouse). Apothecaries were originally the venders and preparers of drugs and compounds used in medicine. Their practice in England is regulated by the act 55 Geo. III. c. 194. See also 21 & 22 Vict. c. 90; 22 Vict. c. 21; 23 Vict. c. 7; 23 & 24 Vict. c. 66; and 25 & 26 Vict. c. 91. The Apothecaries' Company, or the Society of Apothecaries of the City of London, was incorporated by James I. in 1606. Their last charter bears date 6th of December, 1617. [COMPANIES.]

Apothecium. A flat disk, consisting of a nucleus surrounded by a border, in which the asci of lichens are inclosed. It is commonly called a shield.

Apothème (Gr. ἀποθήμη, I deposit). A term applied by the old chemists to some of the varieties of extractive matter.

Apotome (Gr. ἀπότομος). In Geometry, a term employed by Euclid and some of the ancient mathematicians to denote the remainder or difference between two lines or quantities commensurable only in power. Thus, if from the diagonal of a square a part equal to the side of the square be cut off, the remainder is the apotome, and is represented numerically by the expression $\sqrt{2} - 1$. In the tenth book of his *Elements*, Euclid divides apotomes into six classes.

Apozem (Gr. ἀπόζεμα, from ἀπό, and ζείν, to boil). An old Pharmaceutical term for a decoction.

Appalachian Chain. The name of the principal mountain range of Eastern North America, separating the great plains of the interior of the continent from the eastern plains bordering the Atlantic. The chain includes, in all, from three to five parallel ridges of mountains from 3,000 to 4,000 feet high, separated by longitudinal valleys. Known as the Alleghany chain in the states of Virginia and Pennsylvania [ALLEGHANITES], they continue towards the north-east into Canada, being crossed by the valley of the St. Lawrence.

Apparent (Lat. appareo). A term used in Astronomy to denote things as they appear to the eye, in distinction to what they really are. Thus, the apparent altitude of a star denotes the angle which its line of vision makes with the horizon; but the real altitude is found by making a correction for the effects of refraction, which, in all positions except the zenith, causes the star to appear a little higher than it would if there were no atmosphere. The apparent diameter of a planet is measured by the angle made by two straight lines drawn from the eye to opposite points of its disk; the real diameter is a straight line joining those points; while astronomers call the angle under which the diameter would be seen from the centre of the earth, the true diameter. The apparent or sensible horizon denotes the plane which is a tangent to the earth's surface at the place of the observer; the true horizon is a plane parallel to the former, and passing through the centre of the earth. Apparent motion is the velocity and direction

APPARENT HEIR

in which a body appears to move to an observer who is himself in motion. For example: the apparent diurnal motion of the stars from east to west arises from the rotatory motion of the earth, which carries us along with it in an opposite direction. Apparent time is the same as true time, or the hour indicated by the sun's passage over a meridian; while mean time is that which would be indicated by the sun if its apparent angular velocity were uniform.

Apparent Heir. In Law. [HEIR.]

Apparent Solar Day. The interval between two successive transits of the sun's centre over the same meridian. It begins when the centre is on the meridian.

Apparitor (Lat.). Among the Romans, attendants on judges and magistrates, appointed to receive and execute their orders. In English Law, a messenger of the Spiritual Courts of Law, so called from his duty of summoning persons to appear.

Appeal (Lat. *appello*, *I call*). In Law, 1. The removal of a cause from an inferior court to a superior. 2. An accusation of a criminal offence by one subject against another. The bringing decisions of the courts of Scotland and Ireland, or of the court of chancery in England, before the house of lords, is peculiarly termed an appeal in the first sense. Criminal appeals are now obsolete; those on charges not capital have long been so. Appeals of treason and of felony subsisted for a much longer period: the latter had doubtless their origin in the early jurisprudence of the Gothic nations, by which acts of violence or injury were redeemable by a wergild or fine to the party injured or his nearest relative. They were put an end to by stat. 69 G. III. c. 46. [WAGER OF BATTLE.]

Appearance. In Law, the act whereby a defendant in an action recognises the process by which that action is commenced against him: originally by appearing in person, or by attorney, in court; now, by delivering a memorandum in writing to an officer of the court, or otherwise, according to the practice of the court in which the proceedings are taken.

Appellant. In Law, the party by whom an appeal is made; as against an order of magistrates to the quarter sessions, or against the decision of a court of equity to the house of lords. The opposite party is termed respondent.

Appendage (Lat. *appendix*). In Botany, all parts which are regularly arranged round any other part are called appendages. Thus leaves are appendages of the axis; so are all the parts of a flower theoretically. The super-numerary sepals in a strawberry are appendages of the calyx; the abortive stamens that arise from the calyx of a passionflower are appendages of the calyx; and so on.

Appendiculate. Having appendages. The word is sometimes applied to all those plants which are furnished with leaves or appendages of the axis.

Appendix (Lat.). In Literature, a supple-

APPLE

ment added at the end of a work, either to contain portions of the subject which had been omitted, or separate pieces and extracts from other works bearing on it. The latter are termed in French *pièces justificatives*.

Appensus (Lat. participle of *appendo*, *I hang up*). When an ovule is not exactly pendulous, but is attached to the placenta by some point intermediate between the apex and the middle.

Appentis (Fr.). The name given in works upon Architecture to a species of lean-to roof supported upon columns, or brackets, let into the wall to which it is desired to afford a protection.

Appian Way. The most celebrated of the highways leading from ancient Rome. It was constructed by the censor Appius Claudius, A.U.C. 442; and commencing at the Porta Capena, now the gate of St. Sebastian, it extended to Capua, the then limit of the territory of the republic. It was formed of stones, squared and jointed and laid in mortar, and was made wide enough to allow two carriages to pass one another abreast. On each side was a ditch, for the purpose of removing the surface-water falling upon the road.

Apple (Anglo-Sax. *apl*, Ger. *apfel*). The cultivated fruit of *Pyrus Malus*, the crab apple of our hedges. All the numerous varieties that are now so common are said to have originated slowly from improvements of this wild sort. At what period its amelioration commenced is unknown; but, as Pliny was acquainted with several kinds, it is reasonably to be supposed that its improvement is to be assigned to a high antiquity. If it could be true that pippins, that is, seedling improved apples, were introduced only at the end of the sixteenth century, we should have to give the southern nations of Europe the credit of having furnished us with the stock from which the valuable varieties we now possess have been derived. Dr. Prior has, however, lately pointed out that the probable origin of the apple is eastern, and that the garden apple is not, as usually supposed, an improved crab, but the crab a degenerate apple. It was apparently the only fruit with which our ancestors were acquainted before they came into Europe; for with the exception of a few wild berries and the hazel nut, it is the only one for which we have a name that is not derived from the Latin or French. 'The meaning of the word,' continues Dr. Prior, 'is unknown; but as *ap* is in Zend and Sanskrit "water," and *p'hala* "fruit," we might be tempted to believe that it originally meant water-fruit or juice-fruit, with which the Latin *pomum*, from *po*, to drink, exactly tallies.' There is no doubt that apples of some kind have been known in England from long before the Conquest, and although they may have been of bad quality, and fit for food only when roasted, yet they could hardly have failed to produce seedlings of valuable qualities. The crab apple is employed in composition to designate any large fleshy fruit, as love-apple, thorn-apple, pine-apple, &c.

APPOGIATURA

Appoggiatura (Ital. from *appoggiare*, to lean upon). In Music, a small note preceding a larger one of greater duration, of which it borrows a portion of its value.

Apportionment. In Law, the dividing of a rent, &c. into parts, according to the number and proportionate interests of the respective parties entitled thereto.

Appraisement. The valuation of goods sold under distress for rent due, by sworn appraisers, under several statutes. [DISTRESS.]

Apprehension, simple. In Logic, is that act or condition of the mind in which it receives a notion of any object, and is said to be either incomplex or complex: the former being the apprehension of one object, or of several without any relation between them, as 'a man,' 'cattle;' complex, of several, with such a relation, as 'a man on horseback,' 'a herd of cattle.'

Apprentice (Fr. *apprendre*, to learn). A person bound by indenture, for a certain term, to perform services for a master, receiving, in return, instruction in a trade or occupation, and, in most instances, necessary food and clothing. Apprenticeship seems to have originated, together with guilds and fraternities, in the middle ages. Seven years is a common term of apprenticeship in Germany, as well as in England; but other periods, as three and eight, have been customary in different trades, places, and times. The former period was fixed in England by the statute 6 Eliz. c. 4, which regulated apprenticeship throughout the realm in general. By 54 G. III. c. 96, persons were allowed to exercise their respective trades without having served; London, and a few other corporate towns, being excepted. Apprenticeship is, therefore, now only recognised by the law as the mode of learning a trade. The better protection of apprentices was provided for in 1851 by stat. 14 & 15 Vict. c. 11.

Approach, Curve of. In Geometry, the name given to a curve which possesses this property—that a heavy body descending along it by the force of gravity, makes equal approaches to the horizon in equal portions of time. It was proposed by Leibnitz, and its properties investigated by Bernoulli and others.

Approver. In Law, a person who, being indicted of treason or felony and not disabled from giving legal evidence, upon his arraignment, before any plea pleaded, confesses the indictment, and takes an oath to reveal all treasons and felonies that he knows of. The term is now commonly applied to any accomplice who gives evidence (or turns *queen's evidence*) against persons concerned in the same offence.

Approximate (Lat. *approximo*, I draw near to). In Zoology, when the teeth are so arranged in the jaws, that one passes on the side of the next, and there is no intervening vacancy or diastema. The disposition of the teeth in the human species and in the *Anoplotherium* forms an example.

Approximation (Lat. *proximus*, nearest, next to). A drawing near to. In Mathematics,

APPROXIMATION

quantities are said to be approximate which are nearly but not absolutely equal.

In a general sense, the term approximate may be applied to every result of natural philosophy or experimental science. For example, the magnitude of the earth, the distance of the sun, the masses of the planets, in fact, all the elements of astronomy, are only known approximately, and that in consequence of the imperfections of our senses and the errors of our instruments. In mathematics, too, quantities are frequently investigated which, from their very nature, are not susceptible of accurate numerical determination. We have then recourse to methods of approximation, by means of which the values of such quantities can be ascertained to any required degree of accuracy.

Thus, the diagonal and side of a square being incommensurable, we can only determine the length of the former, in aliquot parts of the latter, approximately. The perimeter of a polygon inscribed in a circle is always less than the circumference of the latter, but approximates the more thereto the greater the number of sides. In general, too, we may say that all magnitudes which increase or decrease by insensible degrees are incapable of exact expression by numbers, from the fact that the latter increase discontinuously, in other words by units.

Again, in the extraction of roots, the solution of algebraical equations of a degree higher than the fourth, and in general in all inverse operations where, the *process* and *result* being given, the subject operated upon is required, approximation is our only resource.

The method of exhaustion, by which the ancient mathematicians attempted to find the rectification and quadrature of the circle, was the first instance of a systematic method of approximation. The indivisibles of Cavallieri effected the same object in a more rapid and general manner, and prepared the way for the differential calculus. The invention of the method of infinite series led immediately to general methods of approximating to the values of all radical quantities, and subsequently to the roots of all kinds of compound equations whatever. Vieta was the first who showed how to find successive values of the roots of equations, each approaching more nearly to the true value than the preceding; but his method was tedious and imperfect. Other methods, more easy and general, have been given by various mathematicians; among which, the next known are those of Newton, Halley, and Raphson, and those which have been proposed at a later period by Lagrange, Legendre, Budan, and others. These methods are in general drawn from the most abstruse parts of the theory of equations, and could not be explained in this place with the details necessary to render them of any use. For the best information on the subject, we may refer the reader to the excellent work of Lagrange, '*Traité de la Résolution des Equations Numériques*;' the

APRICOT

'Nouvelle Méthode pour résoudre les Equations Numériques' of M. Budan; the 'Supplément à l'Essai sur la Théorie des Nombres,' by Legendre; and the article *Equations*, in the *Encyclopædia Britannica*, by Mr. Ivory. [EQUATIONS.]

Apricot (Lat. *præcox*, *early*, or Arab. *berkhach*, *butter fruit*). The fruit of *Armeniaca vulgaris*, a native of Kashmir, and probably of the mountains of Cabul, and distributed from Persia and the Oases of Egypt throughout the temperate parts of the world. In its wild state the apricot is a small round pale waxy yellow fruit, rosy on one side, and agreeably subacid: in that state it is dried in large quantities under the name of *mishmish*. In its most improved state it becomes three times as large and sweeter, but it is then apt to become insipid. For the confectioner's purpose, the Brussels and Breda apricots, which are near approaches to the wild fruit, are better adapted than the larger and sweeter kinds. For the history of the word, see Wedgwood, *Dictionary of English Etymology*, s. v.

April. The fourth month of the year. The name is probably derived from Lat. *aperire*, *to open*, either from the opening of the buds, or of the bosom of the earth, in producing vegetation.

A priori (Lat.). In Philosophy and Rhetoric, is a phrase somewhat loosely applied to designate a class of reasonings. It is generally understood to apply to any argument in which a consequent conclusion is drawn from an antecedent fact, whether the consequence be in the order of time, or in the necessary relation of cause and effect;—e.g., 'The mercury sinks, therefore it will rain.' This is an argument drawn from an antecedent in time, not from a cause to an effect. A murder has been committed; a party falls under suspicion, as having had an interest in the death of the deceased, or a quarrel with him: this suspicion is founded on the argument *à priori*, from cause to effect; because the fact of his enmity or interest would afford a cause for his committing the murder. On the other hand, another party falls under suspicion, as having been seen to quit the house at a particular time, having marks of blood on his clothes; these are arguments *à posteriori*, in which we reason either from consequent in the order of time to antecedent, or from effect to antecedent cause. The famous *à priori* argument of Clarke and others in favour of the existence of a God, was an argument drawn from certain primary axioms in metaphysics; while the common course of reasoning to prove the same truth from the visible proofs of design in the works of nature, is an instance of the latter or *à posteriori* form.

Apron (Fr. *naperon*). A piece of lead let into a wall to form the gutter of any portion of a building; it is also placed under the eills of windows or doors, or projections on a roof. It is likewise applied to the planks that are laid at the entrance of a dock; or to the enclosure of brick or of stone inserted at the down side

APTERANS

of a waterfall produced by a lock, or by a cross wall, from the overflow of a pond of still water impounded on the upper side of the dam. The security of an hydraulic work of this description depends very much upon the *firmness* of the apron wall, and *great care* is required in its execution to prevent the effects of undermining or of overthrow.

Apsæ. [ANSIA.]

Apsidal Surfaces. A surface derived from a given one by setting off upon all radii vectores through an assumed origin lengths equal to the normals (apsidal radii) from that origin to the section of the given surface determined by a plane through the origin perpendicular to the radius vector. Such surfaces consist, in general, of a number of distinct sheets, corresponding to the number of normals that can be drawn to any section. The best known surface of this class is the Wave Surface of Fresnel, which is derived from an ellipsoid by setting off upon every central radius vector lengths equal to the semi-axes of the central section perpendicular to that radius. Interesting papers on surfaces of this class will be found in *Mémoires de l'Institut*, vol. vii.; *Transactions of the Royal Irish Academy*, vol. xvi.; *Quarterly Journal of Mathematics*, vol. iii.; *Crelle's Journal*, vols. lii. and liv.; *Annali di Matematica*, vol. ii. &c.

Apsides, or **Apses** (Gr. *ἀψις*, *circle*, or *curvature*). The two points of the orbit of a planet or satellite, at which it is moving at right angles to the straight line joining it with the primary. These two points of the orbit are the two extremities of the major axis, or the points at which a planet is at its greatest and least distance from the sun. The point at the greatest distance is called the higher apsis; that at the least is called the lower apsis: consequently, the higher apsis corresponds with the aphelion, and the lower apsis with the perihelion. The line joining these two points, which is the major axis of the orbit, is called the line of the apsides. It has a slow angular motion in the plane of the planet's orbit; and the time which the planet employs in completing a revolution with regard to its apsides is called the anomalistic period. [ANOMALY; APHELION.]

Aptenodytes (Gr. *ἀπτερος*, *winged*, *δίτρος*, *a diver*). A genus of diving web-footed Natatorial birds, peculiar to the antarctic shores, having wings too short for flight, covered with short stiff feathers, resembling scales, and used as fins or paddles for swimming under water. The legs are short, thick, set far back, with four toes, all turned forwards, three of them long and webbed, the fourth very short. The bill is longer than the head, straight, and slightly curved at the tip; nostrils in the upper part of the bill, concealed in front by feathers. The Patagonian penguin is the representative of the genus.

Apterans, **Aptera** (Gr. *ἀπτερος*, *wingless*). A term including a proportion of the class of insects, the value of which varies in different systems of Entomology. In the Lin-

APTEROUS

mean system it is the seventh order of insects, distinguished by their having no wings. Kirby makes his *Aptera* the twelfth order of the class of insects, but acknowledges that it is not a natural one, and limits the definition of it to those insects which are apterous, or never acquire organs of flight. In Latreille's last system, aptera is no longer applied to designate an order of insects.

Apterous. In Botany, denotes any part of a plant which is destitute of membranous expansions. The term is usually employed in distinction to alate, or winged.

Apteryx (Gr. α , priv., $\pi\tau\epsilon\rho\upsilon\varsigma$, a wing). A genus of birds represented by three or perhaps four species, natives of New Zealand, in which the wings are reduced to a single defensive spur.

Aptychus. A name applied to the operculum of *Ammonites*. It was supposed to be a bivalve shell, as it was composed, like the 'hood' of the *Nautilus*, of two elements, not, however, fibrous and confluent, but calcified and united by a straight suture. The discovery of the operculum *in situ* by Mr. S. P. Woodward, F.G.S., has removed all doubts as to its affinity. It is also termed *TRIGONELLITES*.

Apus. A name applied by Scopoli to a curious genus of Entomostreacan Crustacea, characterised by a flattened, semitransparent, membranous envelope, which protects the body like a shell, having a deep cleft posteriorly; and bearing in front two large eyes, placed close together, with a third smaller one behind. The first pair of legs are long, filamentary, and branched, representing antennae; the remaining sixty pairs are short, compressed, and modified so as to form a respiratory organ; according to the structure which characterises the Branchiopodous, or gill-footed order, to which the *Apus* belongs. The species of *Apus* appear in immense numbers in our freshwater pools; they prey chiefly on tadpoles; and some attain the length of an inch and a half.

Apyrexia (Gr. $\alpha\pi\rho\epsilon\sigma\iota\varsigma$, absence of fever). The intermission of feverish disorders.

Apyrous (Gr. $\alpha\pi\rho\upsilon\varsigma$, from α , priv., and $\pi\upsilon\rho$, fire). A term formerly applied to substances which resisted a strong heat without change.

Aqua (a Latin word, found under modified forms in almost all languages of the Aryan family of nations). Water. It is often almost Anglicised, as in the words *aquavite*, *aquafortis*, *aquamarine*.

Aqua ardente (Sp.). An alcoholic drink made in Mexico from the fermented juice of the *Agave*.

Aqua fortis (Lat.). Nitric acid.

Aqua regia (Lat.). A mixture of nitric and hydrochloric acids, so called from its power of dissolving gold, the king of the metals.

Aqua Tofana. [AQUETTA.]

Aqueductus (Lat.). In Anatomy, the term is applied to certain canals leading from the labyrinth or internal ear to the outside of its bony capsule or os petrosum: one of these, which extends from the hinder part of the ves-

AQUEDUCT

tibule to the posterior margin of the petrosal, is called 'aqueductus vestibuli'; a second canal, leading from the cochlea to the jugular fossa of the petrosal, is called 'aqueductus cochleæ.' The function of the 'aqueducts' is unknown.

Aquamarine (Lat. *aqua marina*). The name under which are comprised varieties of Beryl of clear transparent tints of sky-blue or sea-green. The Aquamarine is used in jewelry, and was known to the ancients as the Beryl. [BERYL.]

Aquarians. In Ecclesiastical History, a title given to sectaries in the early church who insisted on the use of water instead of wine in the celebration of the Eucharist.

Aquarium. More properly *Aqua-vivarium*. A receptacle in which live animals are preserved, in fresh or in salt water, the latter being either transmitted from the sea, or artificially prepared. The art of aquarian preservation has been improved lately throughout Europe, and the Zoological Society of London now have a series of aqua-vivaria in their gardens in the Regent's Park.

Aquarius (Lat.). *The Waterbearer*. The eleventh sign of the zodiac, through which the sun moves in part of the months of January and February. Also, one of the twelve zodiacal constellations.

Aquatic plants. Plants which grow in water, which may be either running or stagnant. In the former case they are called river plants; in the latter, pond plants. Such as grow in the sea are called marine plants.

Aquatinta engraving (Lat. *aqua, water*, and *tincta, dyed*). A mode of etching, by which an effect is produced similar to that of an Indian-ink drawing.

Aquatics, Aquatilis (Lat. *aquaticus*). A name applied by Nitzsch to an order of birds; by Cuvier to a family of Mollusks; by Latreille to a division of Crustacea; by Lamarck to a family of bugs (*Cimicidae*); each of which groups includes animals which live in, swim on, or frequent the margins of waters.

Aqua vite (Lat. In Fr. *Eau de vie*). The name absurdly given to brandy and other intoxicating liquors.

Aqueduct (Lat. *aqueductus*). A term used to express any artificial channel for conducting water; but, generally speaking, it is applied to such buildings as serve to lead the water across a valley, by means of a bridge aqueduct.

The aqueduct of Appius Claudius was the most ancient of those constructed for the supply of Rome, and it is said to have been opened for public use about the year 442 A.V.C. It conveyed water to the city from a distance of between seven and eight miles, by a deep subterranean channel of more than eleven miles in length. The aqueduct of Quintus Martius was a more extraordinary structure. It commenced at a spring thirty-three miles distant from Rome, made a circuit of three miles, and then, forming a vault of sixteen feet diameter, it ran thirty-eight miles along a

AQUEDUCT

series of arches, at an elevation of about seventy English feet above the surrounding country. The upper part of this aqueduct was composed of three channels, placed one above the other, and serving to conduct the water from three distinct sources. In the uppermost flowed the *aqua Julia*; in the second, the *aqua Tepula*; and in the third, or the lowest, the *aqua Martia*; all of which, of course, distributed their waters at different levels. The *aqua Virgo*, constructed by Agrippa, who seems also to have erected similar works in the province of Gaul, passed through a tunnel 800 paces in length. The *aqua Claudia*, begun by Claudius, and finished by Nero, conveyed the water from a distance of thirty-eight miles to the capital. It formed, for thirty miles of its length, a subterraneous stream, and was supported on arches for a distance of about seven miles; and so perfectly were the works executed that it continues to supply the town at the present day. The waters of the river Anio were also conducted to Rome by two different channels; the first was carried through an extent of forty-three miles, and the latter through upwards of sixty-three miles, of which six miles and a half formed one long series of arches, many of them upwards of 100 feet in height. Nine aqueducts existed in Rome at the commencement of the reign of Nerva; five others were commenced by that emperor, under the superintendence of Julius Frontinus, the conservator aquarum; and it appears that at a later period the number amounted to twenty. The supply of water furnished by these different works was enormous. According to the enumeration given by Frontinus, the nine earlier aqueducts delivered every day 14,018 quinaria, which corresponds to 27,743,100 cubic feet. We may therefore assume that the total supply was equal to 50,000,000 cubic feet of water; and if the population of ancient Rome be taken at one million, which perhaps it never exceeded, this would furnish a supply of fifty cubic feet of water for the daily consumption of each individual. It is, however, to be observed that the requirements of the baths and the *naumachiae* rendered the conditions of supply very different from those which prevail at the present day in English towns, where the quantity of water distributed is the nearest to that which prevailed in Rome.

The remains of some Roman aqueducts in other parts of Europe give evidence of the existence of works on quite as magnificent a scale as those of ancient Rome itself. Of these the aqueduct of Metz was one of the most remarkable, and a great number of its arches still remain. It extended across the Moselle, a river of considerable breadth at this place, which it traversed upon a series of arches, and conveyed the water of the river Gorse to the city of Metz. The water was received in a reservoir, from whence it was conducted by subterraneous channels, formed of hewn stone, and so spacious that a man could walk upright in them. The arches appear to have been fifty

in number, and fifty feet in height in the loftiest part; some of the middle ones have been swept away by the flow of ice down the river, but the land arches still remain. The aqueduct of Lyons is perhaps the most curious of these monuments, as it seems to furnish some proof that the ancients only erected the huge bridges for conducting their water from one side of a valley to the other, in consequence of the deficient state of the arts of metallurgy in their days. The aqueduct of Lyons, in fact, contained a reversed syphon in its length, which caused the water to descend, and mount again, 164 feet, in a distance of 2,640 feet; the pipes in this case were lead, and they served to conduct the water from the upper reservoir to a lower one, from whence the flow was resumed. This work effectually disposes of the assertion that the ancients did not know the existence of the hydraulic law, before referred to, of the tendency of water to assume its level in the two branches of a reversed syphon. The aqueduct of the Pont du Gard at Nismes, and that of Segovia in Spain, may also be cited as specimens; of this description of construction in antiquity they are both of them still standing in all their beauty and grandeur, and are good specimens of the care the masters of the ancient world bestowed on these works. The first serves to conduct the stream of the Gardon to the town of Nismes, and it consists of three ranges of arches, the two lower ones being of considerable span; the other has two rows of arches, one above the other, and the height of the edifice is about 100 feet, passing over the roofs of the houses in the city. In Constantinople there are the remains of some aqueducts of a debased style of construction; and in Africa there are the relics of a perfect system of this style of construction.

Aqueducts have been constructed in modern times which rival those of Rome in grandeur; especially in France, where the mania for works of imperial magnificence still survives. One of the most remarkable of these was the projected aqueduct of Maintenon, begun by Louis XIV., under the direction of Marshal Vauban, for the purpose of leading to Versailles the waters of the Eure; it was to have been about 4,400 feet long, and about 200 feet high, and after having cost the lives of many hundred soldiers, and countless treasure, it was abandoned when the first row of arches was turned. The aqueduct of Arcueil, for the supply of Paris, was erected previously to this one, by Jacques de Brosse; and after it we may mention the execution of the Montpeller aqueduct, and more recently still the Pont de Roquefavour, as specimens of French skill in this style of construction. In Italy, the aqueduct of Spoleto is a strange specimen of the application of the pointed arch to this usage; the aqueduct of Caserta is a bold structure for the same purpose; and the aqueduct of Genoa is an illustration of the attempts of engineers to throw off the tyranny of their Roman predecessors in this matter, for

AQUEOUS HUMOUR

it comprises in its length a syphon bridge in the same style as that of Lyons. The aqueduct of the Prince Biscari in Sicily, and that of Lisbon, are good specimens of modern works for carrying aqueducts on a level at a considerable height; the latter has even been said to have been a Roman construction, but there are authentic documents in existence to prove that it does not date beyond the year 1760. The last aqueduct erected for the carriage of a stream of water across a valley in the style of the ancient Romans was the Harlem river aqueduct, on the New York waterworks, which is, after all, nothing more than a bridge of 100 feet in height over the Hudson.

Upon the lines of the canals there have been erected some important aqueducts for the purpose of supporting the water-way at the level once fixed, and also for the conveyance of streams of water for irrigation purposes. Of these works it may be worth while to mention the Irwell, the Scottish Midland Canal, the Lune, the Pont y Cysilte, and the Ellesmere aqueducts, the Guettin and the St. Florentin, the Ganges and the Godavery irrigation canals, all of which are distinguished by a boldness of design and a hardness of construction which place them in a distinguished position in their class. The introduction of cast-iron pipes, which has only taken place within the last century, has, it may be added, superseded the necessity for this expensive style of structures for the main purpose for which the ancients used them.

Aqueous humour. A thin watery fluid holding in solution a small quantity of chloride of sodium and extractive matter, situated in a space behind the cornea of the eyeball, which is divided into an anterior and posterior chamber by a musculo-membranous partition called 'iris,' perforated by the aperture called 'pupil.' The chief use of the aqueous humour is to maintain the convexity of the cornea and support and facilitate the movements of the iris.

Aqueous rocks. Rocks evidently derived from the action of water. All varieties of bedded limestones, sandstones, and clays, all rocks consisting of water-worn pebbles mixed with sand and other foreign substances derived from the natural wearing away of a coast by water, are assumed to be aqueous rocks, without other evidence. Those which contain fragments of marine or freshwater animals, or fragments of vegetable matter accumulated with them in regular layers, have clearly been formed under water; and, generally, wherever material has arranged itself in beds or layers with any degree of regularity, this is the only reasonable explanation of their condition.

The term 'Aqueous rocks' thus includes the whole series of fossiliferous rocks in all parts of the world, besides many rocks buried with and included amongst them that are not fossiliferous. Among the rest volcanic ash is not uncommon in certain localities; and when transported by water, although of volcanic origin, it must be regarded as an aqueous rock.

AQUILEGIA

Almost all aqueous rocks are also so far changed from their original condition as to deserve being regarded as *metamorphosed*. They, therefore, very often pass into **METAMORPHIC ROCKS**, by a series of gradations which renders it impossible to define where one begins and the other ends. Thus, limestones pass from the state of mere mechanical accumulations containing shells and bones, into close compact limestones, where the appearance of shells is exceptional; and thence they pass into crystalline marble. So sandstones pass into quartzite, and clays into slate. Probably, also, many of the true porphyries are only further steps in the same direction. The term *aqueous rocks* is therefore only definite when the origin of the rock is clear.

Aqueous rocks are grouped into various subdivisions in different countries, the divisions having more or less value according to the evidence of fossils. [DESCRIPTIVE GEOLOGY.]

Among metamorphosed rocks those that are aqueous are contradistinguished from the *igneous*. The steps by which they pass into each other are further described in the article on **METAMORPHISM**. Many of the marbles and slates that are altogether crystalline still contain, if they do not consist of, shells, corals, and other remains of the inhabitants of the water beneath which the rock was originally accumulated.

Aquetta (Ital. *little water*). A celebrated poison used by the Romans during the pontificate of Alexander VII. It was probably a preparation of arsenic, and was also known under the name of *aqua Toffana*, from a woman of the name of Toffana, or Tofania, who prepared it at Naples.

Aquifolaceæ (Lat. *aquifolius*, with *pointed leaves*). A natural order of **Exogens**, connecting the monopetalous with the polypetalous subclasses. The whole of the species are either shrubs or trees, and scattered over most parts of the world. *Ilex*, *Prinos*, and *Cassine* are the commonest genera.

Aquila (Lat. *an eagle*). The genus of Accipitrine or Raptorial birds, including the eagles proper, or those species of the Linnean *Falco* which have no trenchant tooth and corresponding notch in the beak.

AQUILA. In Astronomy a constellation above, and adjacent to, Capricornus and Aquarius.

Aquila alba (Lat. *the white eagle*). An alchemical name of *calomel*. The old chemists designated sal ammoniac and other sublimates by the term *aquila*.

Aquiliariaceæ. A very small order of Indian plants, secreting a fragrant resin. They are included amongst rhamnal **Exogens**, and are also allied to *Thymelaceæ*. The species are but little known. The *Aquilaria Agallochum* is the tree that produces the eagle or aggul wood, and which, in all probability, was the aloes wood of Scripture.

Aquilegia. A genus of Ranunculaceous plants remarkable for the curious structure of their flowers, which have five petals pro-

ARABESQUE

duced backwards, into long hollow tubes either straight or curved inwards towards the axis. The petals look something like a cornucopia turned upside down. They are herbaceous perennials, with ternately divided leaves, and are known commonly under the name of Columbine.

Arabesque (Fr.). This is a term applied to a species of ornament, capricious, fantastic, and imaginary, consisting of scrolls of fruits, flowers, and other objects; it was practised by the ancients at a very early period. Foliage and griffins were by no means unfrequent in the friezes of temples, and are seen on many of the ancient Greek vases, and on the walls at the baths of Titus, at Pompeii; and in many other places elegant examples of this species of decoration are to be found. It is, however, to Raphael and Giulio Romano that we owe the most splendid specimens of this style in painting.

The term Arabesque is a corruption, from the supposed Arabian origin of the style. But pure Saracenic ornament has nothing in common with the Italian arabesque of the fifteenth and sixteenth centuries, originally derived from the antique. The purest examples are to be found in the Venetian monuments of the Lombardi and other cinquecento sculptors, consisting of floriated scrolls and figures perfectly executed. The Vatican arabesques of Raphael are occasionally more grotesque, and less æsthetic in their details. In later work, in the so-called Renaissance arabesque, the cartouche or shield is the prominent ornament, which in France, and more especially in the time of Louis XIV., degenerated into a mere play of light and shade, in variations of the scroll and shell which eventually became the Rococo of Louis XV. See Wornum's *Analysis of Ornament or Characteristics of Styles*, 2nd ed. 1861.

Arabin. That variety of gum-exudation from the bark of trees which is soluble in water. Gum-arabic is the common type of such gums.

Arabo-tesesco (Ital. arabo, *Arabic*, and tedesco, *German*). In Painting and Sculpture, a style of art composed of Moorish and Gothic mixed, such as is often found in Venice and the north of Italy. The term is nearly obsolete, and is almost synonymous with Byzantine.

Araceæ or Aroidææ (Arum, Egypt. *aron*, one of the genera). Acid Endogenes, with the flowers arranged upon a spadix, enclosed within a spathe. In hot countries they sometimes become arborescent; in many cold countries they are unknown. Most commonly they arise from a fleshy underground tuber, from which an eatable fæcula is procured by washing away the acid matter. Their flowers are almost destitute of floral envelopes: the sexes are mostly placed in different flowers, and their embryo has a slit on one side. *Caladium arguinum*, now generally referred to *Dieffenbachia*, the dumb cane of the West Indies, derives its name from its juice paralysing the muscles of the mouth, if chewed; nevertheless, the leaves of certain *Caladiums* are eaten by

ARAGONITE

the negroes like spinach, but they require to be boiled in several waters, and are too acrid for an European palate.

Arachidic acid. A solid crystalline matter contained in the oil expressed from the seeds of the *Arachis hypogæa*, a Brazilian plant.

Arachin. A fat composed of arachidic acid and glycerin.

Arachis (Gr. ἀ, priv., and *páxis*, a *chine* or back-bone). A genus of *Leguminosæ*, having the common property of thrusting its fruits into the ground before maturation: hence they are called earth-nuts, or ground-nuts. *A. hypogæa*, a native originally of the West Indies, is now cultivated in all warm climates, the seeds, of the size of peas, being eaten, and also yielding a large quantity of oil, which forms a substitute for that of olives.

Arachnidææ, Arachnida (Gr. ἀράχνη, a spider). A class of Apterous, spider-like Condypods, having the head confluent with the chest, and the body consequently consisting of but two segments, with eight legs, smooth eyes, and the sexual orifices situated on the thorax, or anterior part of the abdomen.

Arachnoid (Gr. ἀράχνη, a spider, and εἶδος, form). Cobweb-like. An Anatomical term, applied to the tunic of the vitreous humour of the eye, and to the thin membrane placed between the dura and pia mater of the brain.

Aræostyle (Gr. ἀραιόστυλος). In Architecture, the style of intercolumniation in which the distance between columns is made equal to four, and sometimes to five, diameters: the former is, however, the distance to which the term is strictly applied. It is principally adopted for the Tuscan order; rarely to any other.

Aræostyle. In Architecture, that style of building in which columns are arranged in pairs, with an interval, generally of half a diameter, between the coupled columns, and of three diameters and a half between the pairs. This arrangement produces a bad effect when the length of the façade is not great.

Aragonite. A peculiar kind of carbonate of lime originally found in the province of Aragon in Spain. It is harder than the common variety, has a higher specific gravity, and crystallizes in hexagonal prisms instead of in rhombohedral forms. A little carbonate of strontia is frequently a constituent of Aragonite; some specimens contain as much as 4 per cent. of carbonate of strontia, and more rarely from 2 to 4 per cent. of carbonate of lead: water is, also, generally present. It is found in Buckinghamshire, at Torbay in Devonshire, in Cumberland, and in many other localities, and is sometimes (as at Carlsbad) deposited by hot springs, and forms the incrustations in the boilers of steam-engines. 'Carbonate of lime crystallized from cool solutions takes the form of calcite, but if their temperature exceed 150° it will become aragonite. On the other hand, crystals of aragonite heated by a spirit lamp, decrepitate and fall into powder, which consists of grains having the form of calcite.' (Jukes,

ARAK

Manual of Geology, 2nd ed. p. 26.) This powder, however, is stated by Gustave Rose to be strictly amorphous. [For varieties of Aragonite, see FLOS FERRI, SATIN SPAR, and MOSSTITA.]

Arak, Arack or Arrac. An alcoholic drink made in Tartary from fermented mare's milk.

Araki. An intoxicating liquor made in Egypt from dates.

Araliaceæ (Aralia, *one of the genera*). An order of Exogens, differing in little from the Apiaceous or Umbelliferous plants, except in having more than two parts in their fruit. They are commoner in hot than in cold latitudes, and form a transition from *Apiaceæ* to *Vitaceæ*. The only wild examples of them in Europe are the diminutive *Adoxa Moschatellina*, and the Ivy, *Hedera Helix*. The celebrated Rice-paper plant of the Chinese is the *Aralia papyrifera*.

Aralo-Caspian region. A great depression in that part of the old world which lies between Europe and Asia, and is separated by the mountains of the Caucasus from the Black Sea and the Mediterranean. This large tract is still covered partly with water, as it contains the great basin of the CASPIAN SEA, which, with the Sea of Aral, collects part of the drainage of the great plains of Asia. The whole district is one of the most interesting points in the physical geography of the Old World. The low flat lands now occupying the intervals between the two great inland seas of the Caspian and the Aral, form part of the *steppes* of western Asia [STEPPES], and are below the level of the waters of the Atlantic. The depression of the Caspian below the Black Sea is about 83 feet. The Caspian is separated from the Sea of Aral by the plateau of the Ust-Urt; and the level of the waters of the Sea of Aral, though not clearly made out, is believed to be much higher than that of the Caspian. Owing to the number of streams entering the Caspian Sea, and its comparatively small depth, its waters are not so salt as those of the Mediterranean. That the Caspian and Aral waters have formerly extended very widely to the north, and that they were at one time connected, is rendered clear by the nature of the rocks in all the vast plains that extend in several directions from them. The recent deposits on the plateau of the Ust-Urt are, however, oceanic.

The present area of the Caspian is about 24,200 square miles, and of the Sea of Aral 4,500 square miles. The depth of the Caspian is believed not to exceed 600 feet in its deepest part, and it is generally much more shallow. The Aral Lake is not so deep as the Caspian. The whole Aralo-Caspian region occupies not less than 100,000 square miles. The two lakes are rapidly filling up by miscellaneous deposits brought in by the numerous rivers that enter into them. Of these the Volga is the principal.

On the whole, there can be no doubt that a

ARBITRATION

great internal sea of brackish water formerly spread over all the low country between the Caspian and Aral seas, covering the present desert of Khivah, and extending far away to the east and south, ranging northward through large portions of the Kirghis steppes into Siberia. This district, when it was separated from the Black Sea and the Mediterranean, did not contain any large quantity of salt water, and the flow of fresh water from the great streams that enter it is amply sufficient to prevent any increase of saltness.

Araneidans, Araneidæ (Lat. *aranea, a spider*). A tribe of the Pulmonary order of Arachnidans, with a coriaceous integument; modified antennæ, or chelicers, consisting of a single joint armed with a claw perforated near the apex for the transmission of venom; breathing by pulmonary apertures, which are either two or four in number, with the abdomen pedicellate, and the arms provided with four or six spinnerets.

Araneosus (Lat. *aranea, a spider*). Covered with hairs crossing each other like the rays in a spider's web.

Arar. The Barbary name of *Callitris quadrivalvis* (*Thuja articulata*), the tree whose wood is chiefly used by the Mahometans of Africa for the construction of their mosques. Its resin is the sandarach of commerce.

Araucaria (Araucanos, *a tribe of Indians in the southern parts of Chili*). A genus of noble fir trees with very rigid branches, having leaves like scales, either small and sharp-pointed, or stiff, spreading, and lanceolate. The cones consist of leaves something like those of the stem, only longer, and containing large seeds. Two species occur in South America, and others in New Holland, Norfolk Island, and New Caledonia.

Arbalest (Lat. *arcubalista, a cross-bow*). This weapon is supposed to have been introduced into European armies by the crusaders, although used long before in the chase (in England as early as the reign of William the Conqueror). The arrows used with the cross-bow were short and thick (quarrels, bolts). The weapon was used in the English armies after the reign of Richard I.; but the Italians, and especially the Genoese, were most expert in the use of it at one time. A large force of Genoese cross-bow men served in the French army at Cressy, where their weapon was found very inadequate to match the English long-bow. Yet so deadly a weapon was it at one time considered, that papal bulls were issued in the twelfth century, condemning and forbidding its use in combats between Christians. It was disused in England, as a weapon of war, in the reign of Henry VIII. Cross-bows were of several sizes: the large or stirrup cross-bow was bent by the foot.

Arbitration (Lat. *arbitratio, from arbiter, an umpire*). In Law, the investigation before an unofficial person or persons of the matters in difference between contending parties. The judgment is called an award. The reference to arbitration may be made, whether

legal proceedings concerning the question referred have been instituted or not. [Award.]

Arbogast's method or calculus of derivations. The principal object of this method may be stated, in general terms, to be the development of any function of a given polynomial in a series arranged according to the powers and products of the variables which this polynomial contains. Taylor's series is the simplest example of such a development, the polynomial in question being there merely a binomial. Arbogast, the inventor of the method, was a professor of mathematics at Strasburg at the close of the last century, at which place his great work entitled *Calcul des Dérivations* was published in 1800. This work, besides giving a solution of the above problem, is remarkable as containing a first attempt at a calculus of operations. The principle of the separation of symbols of operation from those of quantity, which principle has since thrown so vast a light on mathematics in general, is there for the first time practically applied.

Arbor Dianæ (Lat.). *The tree of silver*, that metal having been called Diana by old chemists; it is made by putting quicksilver into a solution of nitrate of silver, which causes the separation of the silver in a beautiful arborescent and crystalline form.

Arbor vitæ (Lat.). An evergreen tree or large shrub, of which several species are found in our gardens. They belong to *Thuja*, a genus of *Coniferae*.

Arboreous (Lat. arboreus). Woody: plants whose stems take a ligneous character are called suffrutescent, or arboreous, according to the degree of woodiness which they exhibit. Plants which grow on trees are also sometimes called arboreous, such as the arboreous lichens, arboreous mosses, arboreous fungi, &c.

Arborescent (Lat. arboreo, to become a tree). Those stems of plants which are at first herbaceous, and afterwards become somewhat woody and tree-like.

Arboriculture (Lat. arbor, a tree, and colere, to cultivate). The art of cultivating trees and shrubs, which are chiefly grown for timber or ornamental purposes. The culture of trees and shrubs grown for their fruits as food, is included under horticulture, and is sometimes called Pomology. The origin of arboriculture may be traced to the progress of agriculture; because, as population increased in any given country, it would become necessary to clear away the natural woods in order to grow corn and other products of the field and garden. After this was done to a certain extent, a scarcity of wood, both for fuel and building purposes, would be found, and then recourse would be had to artificial plantations—Arboriculture. This art may be considered almost exclusively one of modern times; because, though the Greeks and Romans planted both timber and ornamental trees, yet they did so only on a very limited scale, and near their houses, for the purposes of shade or ornament. They also planted the elm and the poplar, for supports to their vines; and they cultivated

osier beds for the purposes of basket-making, but there is no instance on record of their having planted trees with a view of cutting them down either for timber or fuel. Wood for these purposes they procured from the native forests, to the management of which they paid particular attention. In Britain, the first plantations of barren timber on a large scale, with a view to profit, were made during the reign of Henry VIII.; and the kind of tree planted was chiefly the oak, which was raised from the acorn where it was finally to remain. Since that period, the formation of artificial plantations has been on the increase, more especially during the latter end of the last and the beginning of the present century, when the foreign supply of timber was comparatively limited by the war, and when there was a great demand for timber for ship-building. The discovery of coal mines, and more especially the increased facility of working them after the invention of the steam-engine, by providing fuel exclusive altogether of wood, has rendered the necessity of preserving natural woods, and of forming artificial plantations, less in Britain than in any other country in the world. In consequence of this, there is no other country in which so small a portion of its surface is covered with forests; the woods being almost everywhere planted and maintained for ornamental purposes. On the continent of Europe, the practice of sowing or planting barren timber was little known before the time of Louis XIV., though the natural woods both of France and Germany were appropriated, and carefully preserved, for many generations before. At the present time, in consequence of the continental nations depending almost entirely on wood for their fuel, the care of the natural forests, and the formation of artificial plantations, form an important part of the duties of government. In North America, in the oldest cultivated parts of the country, the formation of artificial plantations is barely commencing, while in the back settlements, or newest parts, the felling and clearing of timber is only now taking place.

The science of Arboriculture depends on a knowledge of the nature of trees, of the different agents in cultivation, and of the purposes to which trees are applied in the arts. The practice includes nursery culture: viz. propagation by seeds, by cuttings, layers, grafting, &c., and raising in beds and rows; transplanting, pruning, thinning, and, finally, felling, and the succession of kinds. The nursery culture is carried on in limited spots, called nursery grounds, or nursery gardens, by gardeners or nurserymen; and the other operations in woods, groves, rows, hedgerows, hedges, copses, osier holts, &c., by foresters, woodmen, or hedgers.

Arbustum (Lat.). The classical name for an orchard, hopyard, or vineyard.

Arbutin. A crystalline body contained in the *Arbutus* or *Arctostaphylos Uva-ursi*.

Arbutus (Lat.). A genus of evergreen Ericaceous trees, with pitcher-shaped pallid flowers, and a bullet-like succulent austere

ARC

fruit, rough externally, and containing numerous minute seeds. Several species, all hardy, are known in gardens; the most common of which is *Arbutus Unedo*, the most beautiful *A. Andrachne*.

Arc (Lat. *arcus*, a bow or arch). In Geometry, denotes a portion of a curved line. The right line joining its extremities is called its *chord*. Theoretically, the length of an arc is given by the integration of the expression $\sqrt{dx^2 + dy^2}$, after x and y have been expressed as functions of a single variable by means of the equation to the curve. [RECTIFICATION.] Practically, this length may be determined by dividing the original arc into sufficiently small parts, and finding the sum of their chords.

Arc boutant (Fr.). A term sometimes used in Architecture, to express what is technically called a flying buttress. [FLYING BUTTRESS.]

Arca. The name of a genus of Acephalous Mollusca, characterised by a bivalve and equi-valve shell, having numerous sharp alternate teeth at the hinge. In modern systems the genus is raised to the rank of a family (*Arcadae*), subdivided into the subgenera *Arca*, *Cucullaea*, *Pectunculus*, and *Nucula*.

Arcade. In Architecture, this term is applied to a series of arches, crowned with a roof or ceiling, with a vault or passage underneath the same. The piers of arcades may be decorated with columns, pilasters, niches, and apertures of various forms. The arches are turned, sometimes with rockwork, and sometimes with plain rustic arch-stones, or voussoirs, springing from an impost or platband, and sometimes, though this course is not to be recommended, from columns. They usually have a keystone carved in the form of a console, or sculptured with some device. Scamozzi made the size of his piers less, and varied his imposts and archivolts in proportion to the delicacy of the orders he employed; but Vignolles made his piers always of the same proportion.

Arcanite. A Mineralogical synonym for Glaserite [which see].

Arcanum (Lat. *a secret*). A term often applied to Chemical and Medical preparations by the old philosophers. Thus they called red oxide of mercury, obtained by the action of nitric acid, *Arcanum corallinum*: sulphate of potash, *Arcanum duplicatum*, &c.

Arcouthida (Gr. *ἀρκούτις*, a juniper berry). A small cone (strobilus) whose scales become succulent, and grow together into a fleshy ball: it is the same as *Galbulus*.

Arch (Lat. *arcus*, a bow). In Anatomy, a structure commonly composed of bone or other hard material disposed in a bow-like form, and constituting the chief part of the primary segment of the skeleton: that which rests upon the body of the vertebra (projects backward in man), and spans across the neural axis or trunk of the nervous system, is called the 'neural arch'; that which is suspended in an inverted position (extends forward in man), and encloses the hæmal axis (heart and vascular trunks), is called the 'hæmal arch.'

ARCH

Those in the segments composing the head are called, with their surrounding soft parts in the embryo, 'visceral arches.' Curved portions of the great arterial and intestinal tubes are called 'arches,' as the 'arch of the aorta,' the 'arch of the colon.'

ARCH. In Building, a structure of stones or bricks, or distinct blocks of any hard material, disposed in a bow-like form, and supporting one another by their mutual pressure. In describing arches some technical terms are made use of, which it will be convenient to define. The arch itself is formed by the voussoirs, or stones cut into the shape of a truncated wedge,

the uppermost of which at C is called the key-stone. The seams or planes in which two adjacent voussoirs are united, are called the joints; the solid masonry, A E and B F, against which the extremities of the arch abut or rest, are called the abutments; and the line from which the arch springs at A B b, the impost. The lower line of the arch stones, A C B, is the intrados or soffit; the upper line, the extrados or back. The beginning of the arch is called the spring of the arch; the middle, the crown; the parts between the spring and the crown, the haunches. The distance A B between the upper extremities of the piers, or the springing lines, is called the span, and C D is the height of the arch.

There is considerable difficulty in determining the form which an arch ought to have, in order that its strength may be the greatest possible, when it sustains a load in addition to its own weight; in fact, the determination cannot be accurately made, unless we know not only the weight of the materials the arch has to support, but also the manner in which the pressure is connected; that is to say, unless we know the amount and direction of the pressure on every point of the arch. Supposing, however, that the arch has to sustain only its own weight, and supposing, further, that the friction of the arch-stones is reduced to nothing, a relation between the curve and the weight of the voussoirs may be found by comparing the pressures which are exerted on the different joints. Thus the pressure on any joint, $s q$ for example, arises from the weight of that portion of the arch which is between $s q$ and the summit C H. Now, the portion of the arch C $q s$ H is sustained by three forces: the pressure on the joint $s q$, the pressure on C H, and its own weight. Let $s q$ be prolonged till it meets C D in O, and let n be its intersection with A B. It is a theorem in statics, that when a body is held in equilibrium by three forces balancing each other, these forces are proportional to the three sides of a triangle

formed by lines respectively perpendicular to the directions of the forces. The three forces sustaining $CgsH$ are, therefore, proportional to the sides of the triangle ODn ; for the pressure on sg acts in the direction perpendicular to sg or On ; the pressure on CH is perpendicular to DO , and nD is perpendicular to the direction of gravity. The pressure on sg is, therefore, to the pressure on CH as nD to DO . In like manner, the voussoir $p r q s$ being so shaped, that rp , when produced, meets OH in the point O ; the pressure on the joint rp is to that on CH , as mD to DO . Hence, the pressure on sg is to the pressure on rp as Dn to Dm . We are thus led to infer that the voussoirs ought to increase in length, from the key-stone to the piers, proportionally to the lines Dn , Dm , &c.; for in this case, the surfaces of the joints being increased in proportion to the pressure they sustain, the pressure on every point of the arch will be equal. It will also be observed that the angle nOD is equal to the angle made by a tangent to the curve at g , and the horizontal line parallel to AB ; the angle mOD equal to that made by the tangent at p and the horizontal line; and the radius DO remaining constant, Dn is the tangent of the first of these angles, and Dm of the second; hence the pressures on the successive joints are proportional to the differences of the tangents of the arches reckoned from the crown. From this property, when the intrados is a circle given in position, and the depth of the key-stone is given, the curve of the extrados may be found. When the weights of the voussoirs are all equal, the arch of equilibration is a catenarian curve, or a curve having the form which a flexible chain of uniform thickness would assume if hanging freely, the extremities being suspended from fixed points.

Such is the form which theory shows to be the best adapted to give strength to an arch, on the supposition that there is no superincumbent pressure. But it seldom if ever happens that this is the case, and therefore it is entirely unnecessary, in the actual construction of an arch, to adhere closely to the form determined on the above supposition. Indeed, on account of the friction of the materials and the adhesion of the cement, the form of the arch, within certain limits, is quite immaterial, for the deviation from the form of equilibration must be very considerable before any danger can arise from the slipping of the arch-stones. The Roman arches, which have resisted the attacks of time for so many centuries, are generally in the form of a semicircle. For bridges, it is better to employ a smaller segment of a circle; frequently the elliptic arch is preferred, on account of the beauty of its form.

It has not been satisfactorily ascertained in what country arches were first erected. They do not occur in any of the buildings of the Egyptians that can unquestionably be referred to an ancient date; and if they were not alto-

gether unknown to the Greeks before the period of the Roman conquest, their principal uses appear to have been very little understood. They do not appear ever to have been employed in roofing the temples, or to have formed a part of ornamental architecture. By the Romans, however, the advantages of the arch were well understood at a very remote period. The Cloaca Maxima, which is an arched structure, is referred to the age of the Tarquins; the arched dome is supposed to have originated with the Etruscans, and to have been employed for the convenience of the augurs, affording them a shelter from the weather, and permitting them at the same time to have a view of the whole range of the horizon. In the magnificent buildings erected under the empire the arch is of frequent occurrence; and it was by the Romans that it was first applied to its most useful purposes, namely, the construction of bridges and aqueducts. The Romans, however, appear to have given little attention to the graces of form in the erection of their arches, for they seldom deviated from the semicircle. It was in the middle ages that the pointed or Gothic arch was introduced, when Christians and Saracens vied with each other in giving beauty to their public buildings, by multiplying and combining arches in all possible manners. The associated architects of those ages, says Dr. Robison (*Ency. Brit.* art. 'Arch'), having studied this branch of the art of building with so much attention, were able to erect the most magnificent buildings with materials of which a Greek or Roman architect could have made little or no use. There is infinitely more scientific skill displayed in a Gothic cathedral than in all the buildings of Greece and Rome; indeed, these last exhibit very little knowledge of the mutual balance of arches, and are full of gross blunders in this respect; nor could they have resisted the shock of time so long, had they not been almost solid masses of stone, with no more cavity than was indispensably necessary. It is somewhat remarkable that those architects do not appear ever to have studied or paid any regard to the theory of equilibrated arches. The form which they adopted was strong, and capable of resisting considerable inequalities of pressure, and hence the durability of their constructions. [Barnes; Domes.]

Archæology (Gr. ἀρχαιολογία, from ἀρχαῖος, *ancient*, and λόγος, *a description*). The science or study of Antiquities, and chiefly, in ordinary language, of those minor branches of antiquities which are discarded from the contents of general history: as genealogies, national architecture, manners, customs, heraldic and similar subjects.

Archæopteryx (Gr. ἀρχαῖος, and πτερόν, *wing*). A name originally given by Hermann von Meyer to the fossil impression of a feather which has been found on the two opposite surfaces of a split slab of the Solenhofen (oolitic) slate. This cannot be distinguished from the feather of a bird; and birdlike feathers

have also been found attached to the bones of singular animal, in which the metatarsals are trid, and the carpal bones support a divergent fan of feathers. Another fan of feathers was attached to the long, many-jointed tail. The structure of the head is unknown.

Archæus (Gr. ἀρχαῖος, from ἀρχή, *principle*). A term used by the old chemists and physicians to imply the occult cause of certain phenomena. Van Helmont and Stahl ascribe certain vital functions to the influence and superintendence of a spiritus archæus.

Archæism (Gr. ἀρχαϊσμός). In Rhetoric and Literature, the use of an obsolete expression or phrase, giving an air of antiquity to the passage in which it occurs.

Archangelica. A genus of *Umbellifera* nearly related to *Angelica*. The whole plant is powerfully aromatic. *A. officinalis*, the garden angelica, is a tall-growing biennial, whose leaf-stalks, formerly eaten like celery, are now employed by confectioners in the composition of sweetmeats.

Archangels (Gr. ἀρχάγγελος). A superior order of angels. The term occurs once in Scripture, being applied by St. Jude to Michael.

Archbishop (Gr. ἀρχιεπίσκοπος). The primate of a province containing several dioceses. The term first came into use in the fourth century, and was first employed by Athanasius.

Archdeacon (Gr. ἀρχidiaκονος). An ecclesiastical officer, ranking next to the bishop. His functions were at first confined to attending upon and assisting the bishop in the discharge of his spiritual duties and the management of his diocese, and had at first no jurisdiction. There are now more archdeacons than one in each diocese, the whole number in England and Wales being seventy, and they are employed by their bishops in visiting the clergy of the diocese, and in the despatch of other matters relating to the episcopal superintendence.

Archduke. A title originally assumed by various dukes, but in the sequel appropriated to those of the house of Austria by the Emperor Frederic III. in 1453. It is now strictly confined to the younger sons of an emperor of Austria.

Archegosaurus (Gr. ἀρχηγός, *beginning*, and σαῦρος, *lizard*). This is a genus of Ganocephalous Reptiles, which has been discovered in the coalfields of Bavaria and Westphalia. It presented the same retention of embryonic characters as the *Lepidosiren*, having, like that animal, a persistent notochord, and ossification restricted to the arches and peripheral vertebral elements. The ossified occipital condyles which characterise the skull in better developed *Batrachia* were absent in *Archegosaurus*. Its teeth exhibited folds of cement introduced from the periphery into the substance of the tooth, analogous to the structure in *Lepidosteus*. The under-surface of the body between the head and trunk is defended by broad bony plates, homologous with the median and

lateral large throat plates of various highly organised fishes, e.g. *Megalichthys* and *Sudis gigas*.

Archencephala (Gr. ἀρχή, and ἐγκέφαλος [sc. μὲνός], *the brain*). The highest division of the class *Mammalia*, to which the order *Bimana*, composed of the solitary genus *Homo* (*nosce te ipsum*) belongs. This subclass is distinguished from the other divisions by the enormous vertical and posterior development of the cerebral over the cerebellar lobes, forming what is termed 'a third lobe,' in which are found structures termed by anatomists posterior *cornua* and *hippocampi minores*, complications of the cerebral substance hitherto undiscovered in any other Mammalian. The human brain is further distinguished from the inferior *Mammalia* by the greater size of the cerebral mass, the larger horizontal extent of the *corpus callosum*, and the absence of the lateral perpendicular fissure. With these physiological characters is associated a psychological development, which has raised the human races to their present state of intellectual supremacy.

Archer (from the Latin arcus, *a bow*). A Bowman; one who uses a bow. The use of the bow in war may be traced to the earliest antiquity, and to the history of almost every people. The exact time when the English long-bow began to be used in war is not exactly ascertained: the Normans brought with them the arbalest or cross-bow; but from the reign of Edward II. the long-bow, the favourite national weapon, seems to have been fully established. When fire-arms began to come into use, various attempts were unsuccessfully made, by statute and proclamation, to prevent this ancient weapon becoming obsolete. In France the officers who attended the lieutenant of police were, before the Revolution, always called archers, although provided with carbines.

Arches, Court of. The supreme court of the Archbishop of Canterbury, the judge of which is called the Dean of the Arches, because its court was anciently held under the arches of Saint Mary-le-Bow, in London. It is now held in Westminster Hall. The appeal from this court is to the Judicial Committee of the Privy Council.

Archetype (Gr. ἀρχέτυπος, from ἀρχή, *origin*, and τύπος, *type*). The original of that which is represented in a picture or statue. In the language of Plato, it means the world as it existed before creation in the mind of God. [TYPE.]

ARCHETYPE. In Anatomy, is that ideal original or fundamental pattern on which a natural group of animals or system of organs has been constructed, and to modifications of which the various forms of such animals or organs may be referred. The archetypal figure has been most clearly recognised in the study of the modifications of the skeleton of the vertebrate animals. [VERTEBRA.]

Archil (a corruption of Fr. orseille). A red and of purple dye obtained from the lichens

ARCHIMANDRITE

called *Rocella tinctoria* and *fuciformis*. It chiefly procured in the Canaries.

Archimandrite. A title of the Greek Church, equivalent to abbot; the word *mandra* signifying a *monastery* in the language of the Lower Empire.

Archimedian Screw. A tube wound round a cylinder revolving obliquely. It is an ingenious and primitive method of raising water to small heights, and may still be seen at work in the Netherlands.

Architectural Geology. To the architect and builder a knowledge of rocks is especially necessary, in reference to foundations, to the nature of the material employed, and also as to facilities for natural and artificial drainage. These all depend strictly on geological position. Architectural geology, however, strictly so called, is so nearly the same as engineering geology, and both involve so many similar questions with regard to material, that it will be best to consider BUILDING MATERIALS separately, and refer to ENGINEERING GEOLOGY for remarks on rocks available for foundations, and as affecting buildings upon them. DRAINAGE is also the subject of a separate article. [See also CEMENTS and PLASTERS and the various articles on STONE.]

It does not often happen to the architect to select the site for buildings to be constructed, and thus one very important application of geology in reference to public and private buildings is frequently neglected. A sufficient supply of pure wholesome water is a matter that ought of all others to be secured for every habitation, but this also is too often forgotten till too late.

Architecture (Lat. *architectura*, from Gr. *ἀρχιτεκτων*, an architect). The art of Building, according to certain proportions and rules determined and regulated by nature and taste. Architecture becomes an art at that period only in the history of nations when they have reached a certain degree of civilisation, of opulence, and of luxury. In an earlier state, it can only be reckoned among the trades or occupations necessary to the wants of mankind: its application is then very limited, its use simply furnishing man with shelter. At its birth, however, it assumes in all countries a character which in the sequel stamps it with such remarkable and distinguishing features, that in its grandest developments the traces of its early origin are still discernible. Notwithstanding the interval of so many ages from its origin, we may even trace the general form of architecture to three distinct states of the human race, which necessarily influenced the nature of the habitations suitable to each, and which ultimately became standard models of the art.

People whose dependence for their sustenance was on hunting and fishing, from the natural indolence induced by those occupations and the little industry called for in such courses of life, would not be soon led to construct dwellings. They availed themselves of the natural caverns

ARCHITECTURE

of the rock, or at most hollowed them out, for shelter and protection.

Nations occupied in a pastoral life, through a large portion of the year, obliged, for the sake of fresh pasturage, frequently to change their abode, and thus to lead a wandering life, would wish to remove their dwellings with themselves; hence the use of tents.

Agriculture, which requires continued and active industry on the same spot, doubtless induced man to exert his energies in the erection of solid and durable dwellings. They were necessary for his produce no less than for himself, and the wooden hut with its sloping roof was the offspring of his wants.

It is not, however, to be understood that in every country the art can be traced to a single principle, since among some nations, as will hereafter be seen in relation to Egyptian architecture, more than one will be found to enter into the combination. Causes, independent of the habits of the people, may have had their influence on the formation and taste of different species of architecture; yet these in their turn will be found dependent on the first named. In short, it is to the three states of mankind that we must refer, if we wish to account for those striking peculiarities which prevent us from confounding the art of one people with that of another. In some of its details caprice may have had a share; but in every country the great leading forms spring from principles dependent on the different states of life just enumerated.

Those who have sought for the original types of this art in subterraneous temples and excavations exclusively, have fallen into error. These are found in almost every country. Many of them, such as the famous *Ear of Dionysius* at Syracuse, had been the quarries that furnished stone for their neighbourhoods.

The wooden hut which has been erroneously assumed as the type of all styles of architecture, was unquestionably the model of Grecian architecture. The Greeks, working upon this, transferred to stone the forms of an assemblage of carpentry, a construction which gave birth to the members of what are technically called the orders of architecture. This style, must be remembered, belongs to a nation whose chief occupation is agriculture. In pursuing this theory, a few remarks only will be needed. The first trees driven into the earth for the purpose of bearing a covering or shelter, were the origin of the insulated columns of the portico of a temple, and became one of the most splendid features of the art. As the trees were wider in diameter at the bottom than the top, so were the columns diminished in thickness as they rose. Scamozzi, a pupil of Palladio, imagined that the mouldings at the bases and capitals of columns had their origin in cinctures of iron, to prevent the splitting of the timber; others, however, think that the use of the former was to elevate the shafts from the dampness of the earth, and thereby prevent rot. The *architrave* or chief

ARCHITECTURE

beam speaks its origin. It was the great beam placed horizontally on the tops of the columns, and destined to receive the covering of the entire building. The joists of the ceiling lay upon the architrave, the space in height which they occupy being called the frieze, the ends of the joists in the Doric order bearing the name of triglyphs, from their being sculptured with two whole and two half glyphs or channels. Sometimes the ends of them are sculptured into consoles, as in the composite order of the Coliseum at Rome. The space between the triglyphs was for a long period left open, as we find from a passage in the *Iphigenia* of Euripides, where Pylades advises *Orestes* to slip through the metopes in order to get into the temple. These intervals were afterwards filled up solid; and in the other orders the whole length of the frieze becomes one plain surface. The inclined rafters of the roof projected beyond the face of the building, which delivered the rain free of the walls. The ends of these rafters are the origin of mutules and modillions, of which the former appeared in the cornice with their undersides inclined, as in the Parthenon at Athens. The form of the pediment followed from the inclined sides of the roof, which were regulated in respect of their inclination by the nature of the climate. [Roof.] Here, then, in the skeleton of the hut, may be traced the origin of the different members of architecture, which will be better understood by reference to the subjoined diagram. Figs. 1 and 2 exhibit the parts of a roof in section and elevation: *a a* are the architraves, or traves; *b b* the ridge piece, or column; *c* the king post, or columns of a roof; *d d* the tiebeam, or transtrum; *e* the strut, or capreolus; *f f* the rafters, or cantherii; *g g g g* the purlines, or templa; *h h* the common rafters, or asserece.

Fig. 1.

Fig. 2.

It has been suggested, but with less probability, that the main supports being by degrees placed at greater distances from each other than the strength of the architrave would safely admit, inclined struts were placed from the sides of the columns or supports to the underside of the architrave, to lessen its bearing, and that these gave the first notion of the use of arches in architecture. The subject has been pursued into many more details, on which our limits do not permit us to enter.

The Doric order, doubtless the earliest of the orders, remains without testimony which can satisfactorily assure us of the period of its

invention. But by the time of Alexander the Great the three original orders of architecture had been brought to perfection. Moral as well as physical causes had contributed to bring the arts to this state. In the period preceding the Peloponnesian war, there was a general burst of talent in Greece. It was in this age that the Greeks commenced the rebuilding of the temples and edifices that had been destroyed in the Persian war. This was the epoch of a pure and grand style of architecture, and, indeed, of art generally. The sculpture of that period is marked by the same character of purity, sublimity, and grandeur; and the Elgin marbles, now possessed by this country, exhibit a perfection which has never been approached by modern art, and which we scarcely conceive can be surpassed. It was in this age that the temple of Athena (known by the name of the Parthenon) was erected,—a building which displays, perhaps, the finest model of the Doric order.

The Ionic order seems, at this period, to have likewise received the finishing touches of that grace and elegance of which it was susceptible. This order seems, in the enervating climate of Asia Minor, to have acquired elegance and finish at the expense of solidity. Whether we are indebted for its invention to the people whose name it bears, or whether its origin is to be traced to Assyria, is of little importance. Upon the relation of Vitruvius no dependence can be placed. At the period, however, of the erection of the temple of Athena Polias at Athens, which was about the time we have referred to, it seems to have been brought to a state of perfection. The capitals of this example are splendid specimens of decorated architecture.

By a substitution of acanthus leaves for the olive, laurel, and lotus leaves of the Egyptian capital, Callimachus is said to have invented the Corinthian capital, the feature which distinguishes the Corinthian from the Ionic order. The tale seems an idle one; but though almost threadbare, we cannot omit it, and will give it in the words of the author who has recorded it.

A Corinthian maiden fell a victim to a violent disorder. After her interment, her nurse, collecting in a basket those articles to which she had shown a partiality when alive, carried them to her tomb, and placed a tile on the basket, for the longer preservation of its contents. The basket was accidentally placed on the root of an acanthus plant, which, pressed by the weight, shot forth, towards spring, its stems and large foliage, and in the course of its growth reached the angles of the tile, and thus formed volutes at the extremities. Callimachus, happening at this time to pass by the tomb, observed the basket, and the delicacy of the foliage which surrounded it. Pleased with the form and novelty of the combination, he constructed, from the hint thus afforded, columns of this species in the country about Corinth, and arranged its proportions, determining their proper measures by perfect rules.

ARCHITECTURE

The annexed diagram gives a representation of the circumstance, usually found in architectural works; the reader, however, is at liberty to make his own representation of it, which will most probably be as near the truth as that

which is here given.

Not many examples of the Corinthian order are extant of so early a date as the age of Alexander. Its delicacy and slenderness render it very susceptible of the ravages of time; and it has been suggested, that the value of the material of which the columns and capitals of this order were made, excited the cupidity of the Romans to remove them.

Rome appears to have been indebted to the people of Etruria for its earliest work of any note. It has been supposed that the construction of the immense sewer which drained the city, and in which might be discerned a presage of its future grandeur, is the work of an Etruscan dynasty which existed in Rome in prehistoric times. The genuine architecture of Rome was that of the arch; the Greek forms of their later buildings are simply the result of a fashion for imitation. The patronage of Augustus drew the most skilful Grecian artists to Rome, which now became the capital of the arts. It was under Augustus that Vitruvius wrote his work on architecture, the only ancient text-book on the art that has reached us. Under Agrippa, the son-in-law of Augustus, the Pantheon was raised: one of the most magnificent examples of Roman grandeur. Amongst other superb structures he introduced baths, and constructed a considerable number of fountains, temples, &c. Under the successors of Augustus, the public buildings of the nation continued to increase; but the art began to degenerate in the reigns of Tiberius, Caligula, and Claudius. It could not be expected that it would revive under such a personage as Nero, who deprived the finest statues of their heads to substitute his own portrait on their shoulders. He was, however, a great encourager of buildings on a highly decorated and colossal scale; witness the *Domus Aurea*, built for him by Severus and Celer. The wisdom and greatness of character of the emperor Trajan were infused into the buildings of his reign. The triumphal arches, but especially his column and forum, incontestably prove the rise of the art under his auspices, at which time his architect, Apollodorus, who raised the column to his memory, was highly patronised. It was not long, however, before the art began again to decline. The arch of Septimius Severus betrays an extraordinary falling off; and it is difficult, in such a short period, namely, since the reign of Marcus Aurelius, to conceive how the art of sculpture, more especially, could have become so debased. The details of what is called the goldsmiths' arch indicate the decay of good taste; its profiles are bad, and the ornaments overloaded.

For a short time architecture was prevented

from entirely sinking by the fostering hand of Alexander Severus; but the fall of the western empire completed its ruin: it is, however, from the reign of Gallienus, whose arch proves to what a state it was reduced, that we must reckon the total extinction of the arts. Architecture was indeed most likely to have survived the general wreck, and perhaps was not completely involved in the universal ruin. In an age when no sculptor existed, the baths erected by Diocletian exhibited a grandeur manifest even in their stupendous remains. The palace at Spalatro is another proof of the enormous efforts made by that emperor, and of what the art could then do. About the same time or in the time of Aurelian, were erected the extensive buildings at Balbec and Palmyra: vicious as they are in taste, we are astonished at the vastness of the plans, the boldness of the undertaking, and the funds lavished on their construction.

Though architecture, from various causes, was destined to survive the other arts, its protracted existence could not extend beyond the period of the removal of the seat of empire to Byzantium. The endeavours of Constantine to erect his city into a metropolis that should rival Rome, which he spoiled of its treasures were vain. That which Constantine left behind him in the eternal city and the rest of Italy fell a prey to the fury of the Visigoths. The edifices which they afterwards reconstructed were from fragments of buildings which they had destroyed. The columns which the ruins supplied were used as piers for arcades. Quatremère de Quincy attributes (*Enc. Method.*) the use of the arch springing from columns to the ignorance of the builders of the period, who knew not, he assumes, the mode of connecting the different lengths of an architrave; but it seems scarcely probable that they, who so well knew the mode of connecting the voussoirs of an arch, should have been deficient in understanding the principle in question, which is either that of the arch itself or of the simplest joggling. From this period to the time of the Renaissance all sight of the original types seems to have been lost; and in the end arose a style, under the name of Gothic, which will be separately treated of. But in Italy the old traditions never altogether lost their force. The church of St. Mark at Venice rose in the tenth or eleventh century; it was the work of Greek architects, and is invaluable in tracing the history of architecture. In 1013 the Florentines laid the foundations of the church of S. Miniato; but the most extraordinary monument of the period was the cathedral at Pisa, erected by Buschetto da Dulichio, Greek architect, in 1016: this building is lined both inside and outside with marble, and the roof is borne on four ranks of columns of the same material. The commerce of the Pisans enabled them to explore the Levant, the islands on the coast of Asia Minor, Egypt, and Africa, for the most costly and precious marbles which were used in the work. Painters and sculptors were brought from Greece to embellish their

ARCHITECTURE

buildings, and these contributed to strengthen a taste to which the forms of Gothic art had never been congenial.

In the thirteenth century the church of the Virgin of Assisi was erected in Tuscany, and the castle da Ovo at Naples; the first by Lapo, and the last by Fucio, both Florentines. Nicolo da Pisa, their countryman and cotemporary, was employed on several important edifices in Bologna, Padua, and Venice. His greatest works are the churches at Padua, of St. Anthony and of the Holy Trinity at Florence. Arnolphi di Lapo built the church of Sta. Croce, and designed the cathedral at Florence. All the cities of Italy, indeed, at this epoch seemed to be emulous of outrying each other. Paolo Barbetta was engaged at Venice on the church of Santa Maria Formosa; many works were in progress at Bologna; the marble chapel of the church of Santa Maria Maggiore at Rome, about the year 1216, was executed by Marchione: every effort indicated the speedy revival of classical design. These efforts, however, were confined to Italy; in the other parts of Europe the Gothic style continued to prevail until the Reformation checked the progress of church building.

In Italy architecture was fast reverting to classical ideas. John of Pisa, son of the Nicholas whom we have just mentioned, was employed by his townsmen on the Campo Santo. This public cemetery was in the Gothic style, and is remarkable for the elegant simplicity of its plan and the beauty of its details. It is a singular link in the chain of architectural history: there is no difficulty in discerning the struggle in the mind of the architect to free himself from those Gothic shackles which seemed to hang on it as an impediment to an immediate return to the classic taste of the land. The troubles throughout Europe were stilled at the time when Brunelleschi was called on to finish the cathedral of Florence, of which the octagon had not been covered by Arnolphi and Giotto. Of Arnolphi's ability to cover this space with a dome there can be little doubt; but it would have been a dome ornamented with three or four tiers of galleries externally. 'It appears, however, that in the beginning of the fifteenth century a less expensive or more classical form of dome was demanded, but no one seemed to know exactly how to set about it. Under these circumstances Brunelleschi went to Rome, and studied with the most intense enthusiasm not only the dome of the Pantheon and all the other vaults which the Romans had left in that city; but, becoming enamoured of his subject, he mastered every detail of the style, and became familiar with every form of Roman art. In the year 1420 he returned to his native city, thoroughly a classic in all that referred to architecture; and not only did he, after innumerable complications, complete the great object of his life before he died, but he left his mark on the architecture of the age.' We have quoted the words of Mr. Fergusson, in his recently published *History of*

Modern Architecture (p. 41), because no other writer has so clearly shown that the earlier period of the Renaissance approached very nearly to a genuine revival of art, while in its later phases it soon passed into mere copying. This tendency to imitation, apart from original thought, is betrayed in some designs by Brunelleschi himself. In the church of the Holy Spirit at Florence the classical details are used, as Mr. Fergusson remarks, with singular elegance and purity; but between the piers and the spring of the arch is inserted a fragment of entablature, which in this church has not even the excuse that it is repeated on the wall. 'It is, however, worthy of being remarked here as the earliest instance of the use of one of the typical forms of the Renaissance, which is, taking it all in all, perhaps the most fatal gift of classic art to modern times, as nine-tenths of the difficulties and clumsinesses of the revived art are owing to the introduction of this feature. The first thing the architects of the fifth and sixth centuries did was to abolish this fragment of an entablature, and place the arch direct on the pier or pillar where it ought to be; and the advantage of this proceeding is so self-evident that it seems strange that it could ever have been restored. No single feature can more clearly mark the dawn of copying, to the exclusion of thought, than its reproduction.'

For the influence which this revival of classical design and ornamentation exercised on the countries of Northern Europe, we must refer the reader to Mr. Fergusson's *History of Modern Architecture*. He may be right or wrong in considering Gothic imitations or reproductions worse than classical imitations; but he has traced with the utmost exactness the downward course of the art from the earliest period of the Renaissance, and his chapters on the revived classical design in France and England are especially worthy of attentive study.

ARCHITECTURE, Chinese. As a description of the buildings of China would be out of place in a work of this nature, the subject of the present article is confined to a general view of the principles, the character, and the taste of Chinese architecture.

In China the rise of the arts seems to have been constantly repressed by the state of mechanical drudgery and servitude in which the people are kept. In their painting, for example, the most exact imitation of plants, fruits, and trees, is thought indispensable. Every matter relating to building is the subject of regulation by the police, which, rather than theory, governs its architecture. The laws of the empire detail and enforce with the greatest precision the mode of constructing a *lou* or palace for a prince of the first, second, or third rank, of a *grandee*, of a *mandarin*, &c. According to the ancient law of the kingdom, the number and height of the apartments, the length and height of a building, are all regulated with precision, from the plain citizen to the mandarin, and from the latter up to the emperor himself.

ARCHITECTURE

Herein alone we have sufficient to account for the poverty and want of invention in Chinese art.

In speaking of the principles of Chinese architecture, the word is not applicable in the same way as when we speak of classical architecture, but is meant to apply to those primitive causes which gave birth to it. Character and taste in every species of architecture are the necessary results of these elements. There can be no doubt that the tent is the real model of all Chinese buildings. One of the strongest proofs of this fact is the form of the Chinese roof. Nothing but a tent or pavilion could have given the idea of it. Again, there is nothing like the appearance of a member of wood, similar to our architrave, destined to lie on the tops of the columns, and receive and support the remainder of the carpentry. The Chinese roofs, on the contrary, jut out beyond the columns, whose upper extremity is hidden by the eaves: hence the omission of the use of capitals. It is easy to perceive that extreme lightness must result from this imitation. The spirit and character of tents carried into the construction of cities might, at least in reality, be lost and altered by a change of materials. The semblance of lightness might be found in union with essential solidity of construction; the character would have been intellectually the

Here, however, identity of material has contributed to the identity of the copy with the original. Among the Greeks, whose model was carpentry, the change from wood to stone soon removed the appearance of weakness and lightness that was found in the model. In China the material remains the same, and its architecture of wood still copies the model of wood; hence, the lightness of the original is transferred to the copy. It should, however, be remarked that Mr. Fergusson, whose opinion must carry very great weight on all subjects of Eastern architecture, holds that the model followed by the Chinese was not the tent, but the Buddhist *tee*, or termination at the apex of Buddhist temples in India. This consisted of a square box, in stone, representing undoubtedly the original wooden *châsse* or relic-box surmounted by an umbrella, which, having also been originally of wood, was afterwards worked in stone. Sometimes three umbrellas were placed one over the other; and when, following the ordinary course of development, they came to be copied in stone, a more complete architectural character was given to them, until at last they assumed something of a spirallike form, such as is that of the Chinese pagoda. (See Fergusson's *Handbook of Architecture*.) But, to say the least, however great may have been the zeal with which the Chinese embraced Buddhism, it seems strange that a mere piece of detail, insignificant in size, however important in its use, should have been taken as the type of whole buildings and repeated with astonishing perseverance and uniformity; for the model which originated the pagoda originated also the whole domestic architecture of China.

Lightness is the essential character of Chinese architecture; but there is another characteristic quality, both of the model and the copy, that is observable in the edifices of China; and this is its gay appearance. In this respect scarcely any style presents a more pleasing effect. Its roofs, single and double, brilliantly painted, its gaily diapered porticos, the gloss over the whole surface, the harmony of this species of decoration with the light and flowing forms of the buildings themselves, so please the eye when it is accustomed to see them, that our cold and monotonous mode of decoration may well appear uninviting in contrast.

ARCHITECTURE, Egyptian. The preservation of the Egyptian monuments of architecture, in many instances so perfect as they still appear, is highly calculated to excite our surprise and admiration, inasmuch as ancient Egypt ceased to exist in its splendour long before the period of the earliest histories that have come down to us. Almost, as it were, separated from the rest of the world, by seas of sand as well as water, and bordering on the most savage tribes, it seems indebted to those circumstances for the protection its edifices have received. Had the country received as successors to its early inhabitants a powerful people, if rich and industrious cities had risen on the sites of the old oases, the temples of Egypt would doubtless have been used as quarries admirably suited to the purpose. Arabian hordes, and the almost barbarous and wretched inhabitants of the present day, have indeed built their villages on some of the ancient sites. The terraces of some of the temples serve as floors to modern habitations; and at Thebes, a town of two stories, or rather two stories of towns built on the ceilings of these everlasting ruins, indicate that the means of destruction have not been equal to the natural resistance of works of such solidity.

In a preceding article we have adverted to the three classes of mankind whose different wants had an influence on their styles of architecture. It seems to be no forced supposition that the primitive inhabitants of Egypt used the excavations with which nature furnished them for protection against the heat of a sultry climate. It is true that their country is not the only one in which excavations abound; but in most other places these excavations have been caused by working them as quarries, and no trace of architecture or human abode can be perceived in them. In Egypt, on the contrary, where the caverns still furnish dwellings for the inhabitants, immemorial custom has assigned them to the use of mankind. The immense subterranean apartments of Egypt need not all be placed to the account of luxury in sepulture. Throughout Egyptian architecture its origin appears. A simplicity bordering on monotony, extreme solidity amounting to heaviness, are its principal characteristics. There is an entire absence of everything that can be traced to a type of carpentry, as in the Grecian orders;

ARCHITECTURE

hence it appears likely that at least its type was different, and that this type was cavern excavation. The exception that seems to arise from the use of columns does not militate against the theory; for decoration invariably refers to nature for objects of imitation: and nothing would sooner occur in decorating pillars than the imitation of trees and plants, without referring to them as a type. Here, however, the judgment of Mr. Fergusson must be allowed to carry great authority. A thorough acquaintance with the rock-hewn temples of India has led him to refer all such buildings to an original wooden type. Thus, in his opinion, the sloping walls of the Egyptian temples were not originally suggested by still earlier works in rock, but the latter had abandoned, from the force of physical requirements, the perpendicular supports of their wooden model, and the later architects then came to recopy in stone the changes which had been thus introduced. (Fergusson, *Handbook of Architecture*.)

The honours of sepulture seem to have been the cause of the most stupendous of the Egyptian monuments. Diodorus Siculus tells us that the kings of Egypt expended sums upon their tombs more immense than other kings did upon their palaces. Some have supposed that the pyramids were but immense cenotaphs, and that the bodies of the kings were interred in some neighbouring subterranean spot; in short, that these masses of stone were erected to mislead one from the spot which the body occupied. This, however, would not make them the less monuments of sepulture. Some have attributed to the pyramids a mystic, others an astronomical, purpose.

From Egypt were derived the principal mysteries that passed into other religions, and it was in the darkness of subterranean apartments that those initiations had birth in which secrecy was the first law. Secrecy was there deified under the figure of Harpocrates. According to Plutarch, the sphinxes with which the entrances of their temples were decorated signified that Egyptian mythology was mysterious and emblematic. The number of vestibules enclosed with a series of doors prevented the temple itself from being seen. This, which none were allowed to approach, was small in extent, and in it the sacred animal or its image was preserved. It was in the galleries, porticos, and dwellings of the priests, that the large area which the temples covered was occupied.

Excepting some varieties in the plans of their temples, a sameness of character and uniformity is observable in their fronts, their general forms, and the details of their decoration; the latter being mostly of the hieroglyphic species, certainly the most monotonous of all decorations. To give the reader a general idea of the temples of the country, a diagram of that at Enech is subjoined. With the Egyptians, heaviness seemed to be synonymous with strength, height with grandeur, and size or mass with power. Uniformity of plan is universal. The right line and square was never abandoned,

and, as M. de Caylus observes, there exists no circular monument in this style. In the elevations the uniformity is still more striking; there is no division of parts, no contrast, no effect.

Enech.

As respects the materials for building which the country afforded, we shall speak as concisely as possible. Though palm trees are found about the deserts of Lybia, and near Dendera, timber of every sort is scarce; indeed, the soil is not suitable to the growth of trees. The most common next to the palm tree is the acacia; but, with the exception of the palm tree, most of the trees of Egypt are unfit for building purposes. The oak does not grow in Egypt, and the modern inhabitants import that from Arabia, as well as the fir which they use in their buildings. Brick seems to have been a material used from the earliest date; it was unburnt, being merely dried in the sun. Pocock says it is made of the mud deposited by the Nile which is of a black colour, sandy, and mixed with flints and shells. One of the pyramids described by Pocock was constructed with this species of brick, and unconnected by any cement. Bricks, however, were used after undergoing the heat of the fi at a very early period, as we learn from Exod. v. 6, where we find the Israelites condemned to the labour of making bricks without straw to burn them. Stone of almost every description, marbles, and granite, were to be had in profusion; and these, as we have before observed, the Egyptians were very expert in working.

In construction there must have been considerable mechanical knowledge employed, for some of the blocks of stone were of enormous dimensions; and to form an idea of the quantity used, it is only necessary to mention that the walls of some of their temples extend to the extraordinary thickness of twenty-four feet. Indeed, the walls to the principal entrance of the gate at Thebes are at their base not less than fifty feet in thickness. The stones are all squared inside as well as on the external face; no rubble-work is to be seen; another cause of the surprising durability of their monuments. The roofs are all formed of single blocks of stone from pier to pier; no trace of the arch is anywhere discoverable. In the pyramids the passages are covered with stones inclined to each other, terminating in a point, one stone lapping over the other.

The Egyptian temple, unlike that of the Greeks, which may be almost all taken in at one view, consists of an assemblage of porticos, courts, vestibules, galleries, and other apartments communicating with one another, each of which in size had little relation to the rest of

ARCHITECTURE

the edifice. They were usually in a spot surrounded with walls; and those which were not so surrounded were enclosed in front by a wall engaged to the columns, and extending in height about a half or a third of the shaft. Strabo says that at the entrance of temples was

large paved court three or four times its width in length, which the Greeks called the *dromos*. This was ornamented with sphinxes in rows. Through the *dromos* was the *propylum* or fore portico, which led to another, and that to a third, the number of them not being fixed. Beyond the *propyla* was situated the temple itself (or *naos*), which consisted of two parts, the *pronaos* or fore temple, and the *secos* or sanctuary, which in Egyptian temples was very small, and contained a figure of the divinity, usually represented under the form of some animal. Some of these temples were of very large dimensions; that of Jupiter at Thebes

than 1,400 feet long and 300 feet wide, exclusive of the porticos that led to it. The forms of all the plans are either square or rectangular. The art of designing a plan in modern architecture becomes difficult from the necessity of keeping the apartments within such bounds that they may be covered or roofed, and of arranging the decorations, and of counterpoising thrusts; but the Egyptian architect had no such difficulties to contend with. Columns were brought to the spot and covered at once with masses of stone, all combining without much contrivance with the exterior walls: hence, the abundant use of columns in the interior of their buildings. Great regularity appears in their plans. The temple at Philæ, evidently from its being suited to the form of the island on which it was built, is the only exception. Their intercolumniations are narrow, rarely exceeding twice and a half the width of the column, and usually not more than a diameter and a half. The elevation is always uniform and monotonous, always of one story, and without columns above columns. The pyramidal form seems to pervade every edifice, and the result must be great solidity. Their columns may be considered as of two sorts, circular on the plan, and polygonal; the only difference between the former being that some are, and others are not, sculptured with hieroglyphics. Those which represent as it were bundles of rods or trunks, are generally encircled at different heights with bands like the hoops of a cask, generally in two or three ranges of three, four, or five each. This part of the arrangement seems to have been quite arbitrary. The polygonal column frequently occurs, but more generally where the edifice has been formed out of a rock or quarry. All the columns rise from their bases in right lines, diminishing to the top, without any appearance of entasis or swelling. One can hardly say that any precise proportion is preserved between their height and their thickness. In describing them, we can only say that they were short, thick, and of enormous diameter, the latter in some cases extending to as much as eleven feet.

What are understood by pilasters are not found in Egyptian buildings, (though some quadrangular columns might give that idea), excepting only in the small sepulchral chamber of the great pyramid. Bases are also rarely found; but the capitals of their columns exhibit great variety. In general form they are either square, vase-formed, or swelled; some of them are very elegantly shaped, and decorated with the lotus, the palm branch, and other kinds of vegetation, and occasionally with the human head. They are usually without abacus, and are connected with the architrave by a small dio or square block out of the same piece of stone as the capital. The entablature rarely, if ever, consisted of more than an architrave surmounted by a huge cavetto, which finished upwards with a bead or fillet. This cavetto was frequently ornamented with glyphs and other indentations of the surface, and the wings of the vulture in the centre. The covering of the temple was a flat terrace, though no remains of steps show that they were used.

Some years ago a question was proposed by the French Academy of Inscriptions and Belles-Lettres, whether the Greeks borrowed their architecture from the Egyptians. That question has been well answered by M. Quatremère de Quincy, in the *Encyclop. Method.*, to whom we are indebted for much in this article, and the substance of his answer is as follows:—There is no such thing as general human architecture, because the wants of mankind must vary in different countries. Architecture sprang as well from the huts of Greece, as from the subterraneous excavations of Egypt and the tents of Asia, and from several mixed principles to us unknown: thus the use of the word architecture is absurd. We ought to name the species; for between the idea of architecture as a genus and as a species, there is the same difference as between language and tongue: and to seek for a simple origin of architecture is as absurd as a search would be after the primitive language. If so, the hut of Vitruvius would not be an ingenious fable, as some have said, but it would be ridiculous falsehood if he had pretended that it was the type of all architecture. Vitruvius, however, spoke only of Grecian architecture; and if in Egypt there exists another type, that only proves that the hut was not the type of Egyptian art, but that it was that of Greek art, and that theory would be fabulous which pretended to be universal. Similarity between certain forms of ornament proves nothing more than that between the people by whom they were used there was some interchange of commerce or other intercourse, which could not long subsist without some sort of necessary transfusion of the inventions and habits of one of those countries into the habits, manners, and customs of the other. But in the case of the Greeks even such secondary influences were but slight. When Egypt had been fairly thrown open to Greek commerce, the fashion soon set up of attributing the origin of science, as well as of art, to that mysterious land of which the

ARCHITECTURE

priests, in their own interest, knew well how to enhance the wonders. Hence they were not unwilling to believe that the astronomy of Aristarchus, Ptolemy, and Hipparchus, simply systematised a knowledge for which they were indebted to Egyptian observers. The notion is utterly baseless; but the Egyptians eagerly seized on admissions which chimed in with their national vanity. How completely the theory collapses on careful examination, may be seen by a reference to the treatise of Sir G. Cornewall Lewis, on the *Astronomy of the Ancients*, chap. iii. sect. 3. The independent origin and growth of Greek art cannot be called into question with greater reason than that of Greek science.

ARCHITECTURE, Gothic.—For general purposes Gothic architecture may be described as the architecture of Western Christendom. Speaking more strictly, we must regard it as more especially the architecture of the Teutonic races. It was never really naturalised in those countries in which Roman architecture had predominated.

Few forms of art present such an infinite variety of developments; few have given rise to so much controversy, or been made the subject of a greater number of theories. Without discussing such debated points as the introduction of the pointed arch, or the influence of Saracenic architecture on the Gothic, we may yet trace out the essential differences which distinguish it from the styles of architecture which preceded and gave birth to it, and classify the several developments of Gothic, so as to present a clear view of their leading principles. By this process we may avoid entering on long discussions as to the merits of the systems of nomenclature which have been employed by various writers, while we may lay down the broad divisions under which all possible developments of Gothic architecture may without difficulty be arranged.

The genuine architecture of the Romans was that of the round arch, a form which in their hands might have produced the most astonishing results, had they not chosen to abandon it for foreign forms, or to conceal its real character by a system of decoration in no way suited to it. The real architecture of Rome is seen in its aqueducts, bridges, &c.; the adoption of the Greek architecture of the entablature disguised its real nature and repressed its growth. Christian architecture was in its first stages a return to genuine Roman forms, nor can it be said to have inherited from the architecture of the Greeks more than the ornamentation which it received through that of Rome. If Romanesque buildings continued to exhibit in the capitals of their piers forms which approach very closely to Greek types, their general character was the result of principles which exercised on Greek art no influence whatever.

Before the reign of Constantine, Christian architecture can scarcely be said to have had any existence; and when, at his conversion, the empire became nominally Christian, the existing temples were found unsuited to the requirements

of the faith which he professed. But the basilica, or secular hall of justice, furnished a type as susceptible of development as it was preeminently adapted for the accommodation of large bodies of worshippers. An oblong area, broken by two rows of columns into three divisions, the central being the widest, furnished a plan which might be amplified to any extent, while the tribunal of the magistrate and his assessors presented the model for the arrangement of the altar with the seats of the bishop and presbyters. In this form we have the genuine precursor of the most complicated Gothic buildings; and the type of the Roman basilica is reproduced uninjured in Westminster and Cologne.

In the construction of these basilicas the architecture of the entablature is seen combined with that of the arch.

Their columns were frequently the spoils of ruined heathen temples; but the greater difficulty of procuring architraves led to a larger employment of the arch, and this in its turn to the construction of groined vaults. Here the Christian architects had only to revert to the forms presented by earlier Roman buildings. The Temple of Peace at Rome exhibited the profound knowledge of the Romans in the practice of vaulting; nor was this knowledge lost in the decline of Roman architecture down to the days of Diocletian. In the baths of this emperor are to be seen not only groined vaults in three divisions, whose span is nearly seventy feet, but at the back of each springer a buttress, precisely of the nature of a flying buttress, is contrived to counteract the thrusts of the vaulting. If a comparison be made between this large hall (now used as a church) of the baths of Diocletian with the nave of a Gothic church, the contrast will be found to be more such as must result from the nature and employment of the materials, than from difference of style.

The architecture thus developed, which we may designate by the general term Romanesque, was necessarily a transitional one. The employment of the round arch introduced into buildings the principle of verticality; and although for ages the architects continued scarcely conscious of it, it was constantly changing the character of their designs. The several varieties of this style in different countries exhibit the influence of local traditions and national genius; but through all the many phases of Byzantine, Lom-

ARCHITECTURE

lards, and Rhenish Romanesque, the Anglo-Saxon, and the Norman of France and England, the prominent characteristics of this style are solidity and rest. Yet, with this similarity, the forms developed in the East and West were very different. In the former, every other object was made subservient to the cupola. For the complete development of this design, the nave of the Latin cross was too long, the choir and transepts too short: hence the four limbs are made equal radii of a single circle, and are surmounted generally each with its own dome, which clusters round the great cupola which soars above them.

In England the period of Romanesque architecture extends to the close of the eleventh century, and may be subdivided into the Anglo-Saxon and the Norman. Of the former there are but few examples remaining; and some of the buildings which were begun before the Conquest show the influence of Norman on English art during the reign of Edward the Confessor. As compared with the Norman which succeeded, the style is characterised chiefly by its simplicity or poverty. The arches are always semicircular, the columns single and so low in proportion to their height as to be not more than three and a half diameters high. The windows are little more than slits a few inches in width, and splayed or levelled off on the inside through the whole thickness of the wall. The walls, which are very thick, have no external buttresses. The ceilings were open-timbered, a few vaults being found in crypts. The plan usually presents a nave (sometimes with aisles) separated by an ornamented arch from the chancel; but the elevations seldom show more than one tier of arches with a range of windows above.

The examples of Norman architecture are very abundant, in cathedral and conventual as well as in parochial churches, some of the most splendid specimens being found at Ely, Peterborough, Norwich, Durham, Wimbourn, Romsey, &c. In its earlier stages it differs from Anglo-Saxon chiefly in size and the quality of the work. The round arch is still universal; the window is but slightly enlarged, and remains a mere aperture. But the buildings gained rapidly in height, and exhibit a much

- greater variety of ornamentation. Among the ornaments employed were the chevron or zigzag moulding (1); the embattled frette (2); the triangular frette (3); the nail head (4); the billet (5); the cable (6); the wavy (7); the nebular (8); and some others. Many of these were used

in the preceding period, as well as many which have received no names.

But the great change, displayed in the Norman, is to be found in the elevation of the interior, exhibiting the triple range of (1) pier-

arch, (2) triforium, and (3) clerestory. Here at once we have a style which bears no resemblance to the Greek: but this opposition is only the mechanical result of employing a different constructive form. If the arch had introduced the principle of verticality, it showed itself as yet only in the increased height of the building. There is no subordination or connection of the parts.

The string-courses which separate the pier-arches from the triforium, and the latter from the clerestory, are unbroken; while the arcades of the two latter frequently do not harmonise with the range of the pier-arches. Where the design is strictly of this kind, the building cannot be said to have any Gothic character. It is purely Romanesque. There is no such connection between the parts as that the abstraction of one feature should at once destroy the whole design. They are, indeed, no otherwise connected than as being included under one roof. But the true mark of Gothic is the union of its component parts; and the first approach to such a connection indicates a period of transition. As soon as shafts running up from the piers divided the triforium and clerestory into compartments, the genuine Romanesque character of the building was gone, and the principle of Gothic architecture had taken its place. To this transitional period belong a vast number

of Romanesque or Norman buildings in England and on the continent; while in many the departure from the Romanesque type is so great as to remove them almost from the class of Romanesque to that of Gothic designs. To whatever height a building may be raised, it is clear that its full effect cannot be attained as long as uncut horizontal lines divide the whole structure into separate layers. But although the parts may be subordinated while the round arch is retained, this subordination led naturally to the more frequent use of the pointed arch; and a radical change ensued on the general adoption of a form which, in its occasional employment, had given no indication of its general powers. This feature forced on the mind the idea of relation, and that which is strictly Gothic architecture at once came into existence.

Thus the fundamental characteristic of Gothic is unity. But it is obvious that unity may be attained in more ways than one; it may be secured by the fusion of the parts, as well as by their subordination. Their existence may be absorbed and lost, instead of going each in its degree to make up the whole. These two methods of obtaining architectural

ARCHITECTURE

unity embrace every phase of Gothic architecture, and admit of the systematic classification of all transitional examples. The turning-point has then been reached when the first symptom is seen of a tendency to fuse one form into another. It is clear that, examined by this test, the styles known as the Early English, or Lancet, or First Pointed, and the Geometrical Decorated, or Second Pointed, belong to the first division; while the Flowing Decorated and the Perpendicular or Continuous styles belong to the second. Hence it follows that the one designation of Decorated or Second Pointed, for both the Geometrical and Flowing styles, involves a false classification. There is an entire difference of principle between the two. So long as the forms employed were only geometrical, the later styles could not possibly have been developed: the introduction of flowing or continuous forms (whatever may be their beauty) insured the decline of Gothic architecture. This will be seen by a reference to the accompanying woodcuts.

2

into a series of soft wavy lines, dying into the window arch, and utterly destroyed that subordination of mouldings which was the distinguishing characteristic of the preceding styles. While in the latter the primary mouldings are confined generally to the two principal arches and the circle which they carry, in the former the whole working of a window is on one plane. (*Sharpe's Rise and Progress of Decorated Window Tracery in England.*) [TRACERY.]

But inasmuch as the mullions of a window may be extended upwards as well by straight as by wavy lines, it follows that the Flamboyant of France, not less than the Flowing Decorated of England, is in principle identical with the Perpendicular or Continuous style. The question of beauty is, manifestly, entirely distinct from the principle involved in a style. Every change from one principle to another must in architecture be accompanied by a period of transition; and it would seem that to such periods we are indebted for the most beautiful and magnificent designs. On the introduction of the ogive form the declension of

Gothic architecture became very rapid. 'Even the most important features were at length merged in the production of a collective unity. The capitals of the piers became more wiry and

By a comparison of the Flowing Decorated with the Geometrical, we see that the new principle is exhibited first of all in the windows, by the employment of the ogive in place of circular forms—geometrical tracery being, in strictness, confined to the use of circular figures only. (See *Freeman's History of Window Tracery.*) But the ogive forms once introduced soon converted the whole tracery of windows

slender (1), and at last were removed altogether (2). String-courses and bands became fewer in number. The pier-arches assumed the

ARCHITECTURE

ogeed termination (3), from which, as from the apex of every opening of the triforium, straight lines ascended without interruption till they were lost in the interlacing tracery of the vaulting. Thus, that very form of architecture—the truest, the most beautiful, the most magnificent, that the world has yet seen—the genuine offspring of the pointed arch, whose highest triumph was the achievement of a glorious unity of separate existent parts—gave birth, by a strictly logical process, to a wholly antagonistic idea, which necessitated the abandonment of the very feature which had been its essential and most splendid characteristic; and, by a growth of marvellous rapidity, the principle of the subordination of parts ended in their ultimate absorption.' (*Edinburgh Review*, No. 213, p. 134.) [RENAISSANCE.]

In Germany, the Gothic architecture followed a course similar to that of English Gothic, with one remarkable exception. It has nothing answering to the style known as Early English (or Lancet, or First Pointed). The pointed arch and lancet window, adopted first in France, had effected a complete change in English buildings, while the old forms continue to exercise all their influence in Germany. There is nothing in England of that unswerving retention of primitive character which marks the Rhenish Romanesque. It is not surprising, therefore, that, when these forms were once abandoned, German architecture should make a sudden advance, comprising in one stage the interval extending from the Norman to the Geometrical Gothic of England.

Of the many theories, some plausible, others more or less absurd, which have been advanced to account for what is called the invention of the pointed arch, it is scarcely necessary to say more than that the simplest, and therefore the most attractive (that, namely, which traces it to the requirements of vaulting), is as untenable as the rest. Prof. Willis, in his *Remarks on the Architecture of the Middle Ages*, has shown that so far was this form from being necessary for the vaulting of rectangles of different lengths and breadths, that several methods for accomplishing this had been employed for a long time, and continued in vogue long after the change from round to pointed forms.

The great criterion of the differences between each style of Gothic architecture, whether in principle or in detail, is to be sought (as has been already noticed) in the tracery of their windows. Here the subordination of parts is most clearly brought out in the earlier stages of the Geometrical Decorated; while the substitution of the vesica for the circle and triangle first betrays the introduction of a different principle from that which had brought about the change from Romanesque into Gothic.

As compared with the cathedrals of France and Germany, the great ecclesiastical buildings of England exhibit great differences of plan and design. In England, after the Romanesque period, the square end was substituted in churches for the apse. In France the retention

of the more strict basilican form led to a great development of the idea of verticality. The cathedrals of Amiens and Cologne are not so long internally as those of Canterbury, Winchester, and York; but they exceed the latter in height by fifty or sixty feet. This great internal height involved also the retention of double aisles, of which the outer round the apse is formed into a series of chapels themselves apsidal; but it also involved the modification or abandonment of the external features which are the great characteristics of English churches. It was impossible to raise such central towers as those of Canterbury and Lincoln in buildings whose height varies from 120 to 180 feet; and even the western towers cease to bear the prominent character which they exhibit in English designs. The great end of the continental architects was height; the English architects, with a more marked external outline, compensated for comparative want of height by the greater length which furnishes an almost boundless perspective in such buildings as the abbey church of St. Alban's and the cathedrals of Winchester and Ely. The development of Gothic architecture in England and on the continent was in principle the same; but it exhibited in each case a distinctive national character which it is impossible to mistake.

Periods of English Architecture.—In attempting to assign dates for the duration of successive styles in architecture, it must be remembered that each stage is preceded and followed by a period of transition, and that hence a building which chronologically belongs to a Romanesque period may to an indefinite extent exhibit a Gothic character, while in others the characteristics of a former style may be retained when that style has passed almost wholly out of use. This intermingling of styles is especially discernible in the later stages of Gothic, and most of all in the periods which are commonly classified under the name of the Decorated style. This style has philosophically no existence, and really consists of two stages, one of which adheres to the true Gothic principle, while the other has virtually abandoned it. The names to be assigned to these two stages remain still a subject of controversy; but it is comparatively a matter of indifference whether with Mr. Petit we speak of Early Complete and Late Complete Gothic, or if with Mr. Sharpe we call them respectively Geometrical and Curvilinear, so long as we remember that the principle of the Late Complete Gothic, or the Curvilinear, is identical with that of the Rectilinear (or Continuous or Perpendicular) style.

Thus the lines of demarcation between one style and another are not so sharply drawn as is commonly supposed; and there are subdivisions of styles even where we speak generally of only one. In the architecture of this country three stages may be traced before the prevalence of that form of Romanesque which is especially associated with the Norman

ARCHITECTURE

conquerors of England. The first stage is little more than a debased form of Roman work; to this time belongs Brixworth church, which was probably built in the latter part of the seventh century. Of the second period the church at Earl's Barton is perhaps the best specimen. During this time the use of masonry was extended to the smaller churches, which had previously been built of wood, while the distinguishing peculiarities of Saxon work were still retained in all. (See Freeman's *History of Architecture*, p. 217.) In the following period, the use of wood was generally discarded for that of stone, and the buildings exhibited less and less of the peculiarities of timber construction. The straight-sided arch became more rare, and the shaft was substituted for the baluster. To this period belongs part of the church of St. Peter-le-Gowts, and of the cathedral of Oxford, prior to the changes which it underwent at the end of the twelfth century.

If the Norman conquest was speedily followed by the prevalence in England of that form of Romanesque which had already raised some splendid monuments in Normandy, the introduction of this style was not entirely owing to the defeat of Harold at Hastings. Norman architects had already been employed by Edward the Confessor, and the church which Harold built for the secular canons of Waltham so far exhibited the characteristics of Norman Romanesque as to make the date of its erection a matter of doubt and controversy in the present day. But we are told in plain terms that Edward built his abbey at Westminster in a new style, and the work of Harold at Waltham is only a further proof of the extent to which the Norman Romanesque was influencing the architecture of this country. No style has left behind it more enduring memorials. During the period of its prevalence, all the cathedral and most of the conventual churches in England were rebuilt, while innumerable new buildings were raised throughout the country. It is scarcely necessary to adduce instances, but the cathedrals of Ely, Peterborough, Norwich, Chichester, and Durham, may be mentioned amongst the most magnificent examples.

But although the Norman Romanesque must be regarded as a substantial and not merely as a transitional style, it must be remembered that in proportion as it combined all the parts of a building into one harmonious whole, it tended to introduce the principle of Gothic architecture, and this tendency became manifest during the reign of Stephen, A.D. 1135-1164. The round arch was now more and more superseded by the pointed arch, and clustered shafts took the place of columns. From the character of the windows, which exhibited merely the grouping of apertures, without any approach to genuine tracery, this period has been known as the time of the Lancet style (or the First Pointed in the nomenclature of the Ecclesiological Society). Among the more remarkable examples of the Lancet or Early English style,

may be mentioned the abbey of Whithy and Beverley, the presbytery of Ely Cathedral, the cathedral of Salisbury, the transepts and choir of Worcester, &c.

The commencement of the next period, which marks the prevalence of the Geometrical or Early Decorated style, must be dated from the introduction of tracery, which at the first was confined to purely geometrical forms. This period (allowing for the time of transition) extends down to the reign of Edward II.; and among the most important examples may be mentioned portions of Westminster Abbey, in its earlier stage; Merton Chapel, Oxford; Exeter Cathedral, Lichfield Cathedral, the spires of Salisbury and Norwich.

The abandonment of pure geometrical forms marks the declension of real Gothic architecture; but the employment of curvilinear forms was introduced long before any marked change in the character of English architecture became perceptible. Although, however, there could be, in strictness, no intermediate form between geometrical and flowing tracery (Paley's *Architecture*, p. 173), yet the two styles might be combined, not only in the same building, but even in the same window. Hence it becomes extremely difficult to classify the buildings belonging to this period of transition. As specimens of such intermixture may be mentioned the eastern windows of Carlisle and Bristol cathedrals, and the western window of Exeter. But this period was rapidly succeeded by what is commonly known as the Perpendicular, in which the tracery was carried to the head of the window in straight lines instead of flowing lines. The full development of this style may be assigned to the reign of Edward III.; and to it belong the naves of Winchester and Canterbury, the encasing of the choir of Gloucester, the church of St. Mary Redcliffe, Bristol, &c. Of the history of this style we have already spoken; and we need therefore only specify among its later examples the chapels of King's College, Cambridge; St. George's, Windsor; and the still more sumptuous chapel of Henry VII. at Westminster.

One of the most striking features which distinguish English from continental architecture is the employment of wood for the roofs whether of halls or churches. To the former they were applied from the reign of Edward III. About A.D. 1400 they were employed in churches, wherein prior to that date stone vaulting appears to have been more common. The Norman castles had their keeps and halls vaulted with stone, as was the case with those in North Wales built by Edward I.

Our limits preclude us from adverting to many fine specimens of ecclesiastical architecture in Scotland; but the abbey of Melrose and Kelso, founded by David I., as well as those in Dryburgh and Jedburgh, all in Roxburghshire, show that the art was carried to as great perfection north of the Tweed as in the southern parts. Roslin and Holyrood Chapels, for richness and variety of ornamental carvings

ARCHITECTURE

(the first erected by Sir William St. Clair), cannot be exceeded. Its plan is without parallel in any other specimen of the fifteenth century. The latter was finished by James, the second of that name, in 1440; and is a beautiful specimen, with flying buttresses, more ornamented than any even in England.

It would be impossible here to enumerate the palaces and private Gothic buildings of this country, of which parts still exist in the remains of the ancient palace at Westminster, Eltham, Kenilworth Castle, Hampton Court, and in many other places. The following list exhibits the dimensions of the different cathedrals in England.

Total Internal Length in Feet		Internal Breadth of Transept	Choir		
			I.	D.	P.
Old St. Paul's . . .	500	248	165	42	88
Winchester . . .	545	186	138	—	78

ARCHITECTURE, Grecian.—Grecian architecture, which was transplanted after its perfection to an Italian soil, where it assumed almost another form, will not require an extended notice in this place. The particular detail of the changes it underwent will be found in the articles DORIC, IONIC, and CORINTHIAN orders. Its origin and types have already been considered in the article Architecture, and an explanation of its terms will be found under their several heads in this work.

The value of the legends which ascribe to Cadmus the introduction of the worship of Egyptian deities, with the practice of quarrying stone, has been already examined in the article on Egyptian architecture. The Greeks at an early period had raised some extraordinary structures, such as the treasury of Minyas, king of Orchomenus, and the walls of Tiryns, which still attest the truthfulness of the Homeric poet and of Pausanias. From the Homeric writings we find that the form of government was patriarchal, that the chief buildings were the palaces of the princes, and that the altar was the only structure for sacred use, and that even this was little more than a hearth, on which the victim was prepared for the meal; for, until

after Homer's time, no regular priesthood existed in Greece. It seems probable that the temple was not used until the kingly and sacerdotal offices were separated. It would be difficult, perhaps now impossible, to trace the degrees from the use of the simple altar to the establishment of the regular temple, or when the latter became a necessary appendage to the religion of the country. The houses of the Greeks appear to have been simple in plan, and at an early age consisted of two stories, as was indeed the case with the dwellings of the East mentioned in the Scriptures.

Goguet (*Origine des Loix*) says that Asia Minor was the cradle in which architecture was nursed, and thinks that to this country we are indebted for the invention of the Doric and Ionic orders. All authors seem to admit that the Corinthian had its birth in the mother-country, and not in the colonies. Perhaps the earliest temple recorded is that of Zeus or Jupiter at Olympia, which, according to Pausanias, must have been built 630 years before the Christian era. If Livy be right, that of Artemis at Ephesus was of a period little less remote, and at this time the science of mechanics was in its infancy; for even in the time of Thucydides, though the powers of the crane were known, they were not commonly applied for the purpose of raising weights.

Admitting that the system of imitation in the Doric order was founded on the elementary forms and parts of the hut, it was in that case guided by the principles that nature herself adopts in her operations; otherwise no bounds would have limited the caprice and imagination of its improvers. In the copy, no part is precisely similar to the model; but an analogy, and that very strong, is observable. The proportions and parts of the Doric order, in different examples, plainly indicate that the Grecian artists considered themselves restricted only by general rules, inasmuch as we find them varying the height of the Doric column from four diameters to six and a half [Doric ORDER], while the height of the entablature varies in terms of the diameter from 1·72 to 1·97. The intercolumniations used in the Doric order at Pæstum, Corinth, and Segesta, and in the Parthenon, are equal to about one diameter of the column. They are about a quarter of a diameter more at the Temple of Theseus, whilst in an example at Syracuse they are somewhat less than a diameter.

The age of Pericles exhibited almost all that art could be imagined to accomplish; the Peloponnesians and their colonies had erected the temples at Corinth, Nemæa, Pæstum, Syracuse, and other places in Sicily; thus, in a space of little more than three hundred years from its introduction, it appears that the art was raised to the summit of perfection. It is probable that the Ionic order is not far behind the Doric in antiquity. In the former, the different examples exhibit a variety not less to be noticed than that which we have observed in the latter order. The height of

ARCHITECTURE

the Ionic column varies in the three examples of the temples on the Ilissus, of Athena Polias, and Erechtheus, from eight diameters and a quarter to nine and a half; but in the heights of the entablatures there is not so much variation. The cornice of the Grecian Ionic may be considered as bearing a constant ratio to the whole height of the entablature, as 2 to 9; while the whole height of the latter seems nearly constant at two diameters in height. This order received the addition of a base to its shaft, which was wanting in the Doric order; but for the varieties the reader will refer to that article in this work. The volutes, which are its distinguishing features, are found with many varieties. In the temple on the Ilissus, in that of Athena Polias at Priene, and that of Apollo Didymæus, the volute contains only one channel between the revolutions of the spiral; whereas in those of Erechtheus and Athena Polias at Athens, each volute has two distinct spirals with channels between them. In the former of these two the column terminates with an astragal and fillet, just below the eye of the volute; in that of Athena Polias with a single fillet. In each, the neck of the capital is ornamented with honeysuckles. The shafts are usually cut with flutes of an elliptical form, to the number of twenty-four. These flutes vary from those of the Doric order, in their separation from each other, through the intervention of fillets.

The distinguishing feature of the Corinthian as of the Ionic order is the capital. But our knowledge of the Greek Corinthian order is unfortunately circumscribed, from the destruction and decay to which from its extreme delicacy it was exposed; nevertheless, under even these circumstances, the few examples that remain induce a supposition that it was not in such high estimation as those we have already named, inasmuch as the only examples that have come down to us are found in what is called the Tower of the Winds, and the Choragic Monument of Lysicrates, both at Athens. But the former of these is scarcely to be classed among examples of Corinthian, and the latter (as we now understand the Corinthian order) is in some respects a little eccentric in character. In the Choragic Monument the height of the entablature is somewhat less than a fifth of the total height of the order. The base varies little from that of the Ionic order, excepting in the non-appearance of the horizontal fluting in the upper torus.

To the orders enumerated may be added one scarcely to be named here, because apparently under no rules which regulated its proportions, namely, the figures called Caryatides, which were employed for the support of an entablature. For the supposed account of their origin, the reader is referred to the article **CARYATIDES**.

The only subject remaining for notice, under this head, is that of the roofs of the Grecian temples. They consisted, of course, of two inclined sides, which at the ends formed a

pediment. From experience it was soon found that the angle at which the sides of a roof should be inclined to the horizon should be such as effectually to shelter the interior of the building from the inclemencies of the seasons. Hence greatly inclined roofs are indispensable in northern climates; the reverse as the climate approaches the equator: but this will be more fully explained under the article **Roof**. Here we shall merely state that, according to the hypothesis, the inclination of the sides of a roof should, for the latitude of Athens, be $16\frac{1}{2}$ degrees. The actual inclination of the roof of the temple of Erechtheus is $16\frac{1}{2}$ degrees, temple of Theseus 16 degrees, the Parthenon 16 degrees, and that of the Propylæa $14\frac{1}{2}$. Comparing the law with the Roman examples, the climate would require an inclination of the sides of the roof with the horizon of 22 degrees, and the variation between the examples remaining is from 22 to 24 degrees.

The invention of the arch does not at present appear to belong to Greek architecture.

ARCHITECTURE, Indian.—It is very properly observed by M. Quatremère de Quincy, that, in spite of all theories, an infallible mode of estimating the state of the architecture and other arts of any people is by their representations of the human form. Every people, he says, who during a number of ages have persevered in falsely representing the figure void of all proportion, and according to a certain barbarous and ignorant routine, must be convicted of a want of that sentiment which leads to a knowledge of truth, and of that intelligence which knows how to find in nature rules for the choice of forms and arrangements applicable to the art of building. Every people which does not manifest in its works this conformity to nature must be ignorant of the arts of imitation, and all their productions must be the result of an irregular taste. These remarks particularly apply to Indian architecture, whose exact antiquity is still a problematical question. In a country abounding with deserted monuments, where are found the traces of an ancient language now no longer spoken, books no longer understood, and a mythology which bears the closest resemblance to that of Greece, we are naturally led to suppose that civilisation existed at a very early period. These opinions would seem to be corroborated by the extraordinary chronologies which the modern Indians have produced as incontestable authorities for their remote antiquity. The chronology, however, of the Hindoos will not bear the test of strict investigation: neither has any inscription or historic monument been discovered, nor any annals found, which give us an idea of the changes, revolutions, or prosperity which the country may have experienced.

It is natural to suppose, that the subterraneous or excavated monuments of India are prior in date to raised or constructed works; and yet, in point of fact, we find in the former neither less minuteness of details, less caprice in form, nor less profusion of fantastic ornament, than in

ARCHITECTURE

the latter. Hence the monuments themselves afford us no clue to their respective antiquity. The fact, however, seems to be established, that during a long period the settlers in the great Indian peninsula left few or no architectural monuments, and that this continued to be the case until a change had come over their religion. This fact Mr. Fergusson ascribes to the nature of their belief, 'when every man stood forth in the presence of his God and without intercessors offered up his prayers with the prescribed forms, . . . always feeling himself in the immediate presence of the Deity, and appealing directly to his mercy. . . . Among such a people it would of course be vain to look for any monuments of importance.' (*Handbook of Architecture*.) But whether the lack of buildings is to be ascribed to the purity of their faith, or, as Gibbon asserted in the case of the Germans, to a want of ingenuity, it may be fairly inferred that the change to Buddhism brought about an increased activity in art as a government.

Construction is a term scarcely applicable to the greater number of works of Indian architecture. It means the raising of a building composed of diverse materials, or of pieces joined together to form a mass; hence it cannot be properly applied to an excavated structure. The edifices of India may be divided into two classes, the quarried and constructed; the last are mostly those towers improperly called pagodas. To the unconstructed class belong the seven large pagodas of Mavalipuram, which consist of large masses of stone more or less engaged to the earth, and contiguous to similar masses. These masses were shaped and sculptured externally in accordance with their general form, partly pyramidally and partly by irregular zones, in the same style as the pyramidal tower of the constructed pagoda. No order is apparent in the respective dispositions of the masses, neither is regularity in the plan and exterior form to be detected. These edifices are extremely small in the interior, being hollowed out of the mass, and remind us of the monolithic temples of Egypt, cut out of immense blocks of granite, which, as Herodotus tells us, were removed to very considerable distances. In other respects, there was clearly some resemblance between the art of India and Egypt; it is found in the excavations of monuments, and in working large natural masses of stone in their original situation. But we are scarcely justified in inferring from this similarity of taste that there was communication between the two nations; and still less are we at liberty to infer a resemblance of style in architecture from a similarity of practice; for nothing is more unlike the Egyptian than the Indian style of architecture; and in the end it will be seen that, except in the practice of excavation, there is no similarity at all. The dimensions of the pagodas, as they have been called, compared with those of the Egyptian pyramids, not less than their execu-

vated temples, have been much overrated by travellers. Of the latter, the dimensions are generally moderate, and the difficulty of their execution could not have been very considerable. If the description that comes to us be correct, the latter are hollowed out from quarries of calcareous stone, and the dimensions are on so small a scale, that even the celebrated temple at Elephanta is only 130 feet long, 110 feet wide, and but 14 feet 6 inches high. The operation of hollowing out a cavern of this sort can scarcely be dignified with the name of art; but in the pagoda construction we must admit some display of that which at least approaches it. The pagodas are, in many instances, of considerable height; but to compare them with the pyramids of Egypt is out of the question. These, the only buildings of much height, are pyramidal in general form. Sonnerat (vol. i. p. 217) gives us some idea of them: he says, 'Around the most celebrated temples the surrounding walls are thick and much raised. On each side is a gate surmounted by a pyramidal tower, with a curved mass of enormous size. The tower is loaded with figures,' &c. &c. If we may trust the representation of the pagoda of Chillambaram by M. Durocher de la Perigone, given by Cuyas in the 31st vol. of the *Mémoires de l'Académie*, the pyramidal form is therein strongly marked. In it the height of the whole is but 120 feet, and at its base it is but 80 feet wide. The termination is not in a point, but is truncated at a height which makes the plan of its summit about 36 feet wide. The pyramid is of unequal sides, the flanks being much narrower than the faces. But the largest of these monuments is that described by Lord Valentia, namely, the pagoda of Tanjore, which he considers the finest specimen of this species of building. This is 200 feet high, placed on a basement of 40 feet in height. The pyramidal mass rises by twelve sets-off, or bands, sculptured in various ways. Such samples of masonry, however, required no great display of constructive skill for their execution, either in working or transport of the materials. At Chillambaram, for instance, the pyramidal part is constructed to the height of 30 feet only in masonry, the remainder being of brick. The mass is coated with ornaments of stone and of a species of white cement of the country. As in Egypt, none of the monuments of this country exhibit any trace of the arch: the coverings of the apartments are all horizontal, and the dimensions in all are necessarily limited by the want of that expedient which, in modern architecture, has been the parent of the most stupendous monuments of which art was capable. The ceilings in Indian architecture are of enormous blocks of stone, laid on the supports on which the buildings are constructed, being the simplest and most inartificial mode of contriving a covering to an apartment. It must be apparent to every one, that the art of India was many leagues below that of Egypt. Though, in the last-named country, art was limited by the

ARCHITECTURE

habits of the people, yet it is equally certain that their knowledge in the use of materials was of a high character, and that their skill in masonry was carried to great perfection.

That which is known to the architect by the term ordonnance, which means, in its most extended sense, the composition of a building and the due arrangement of its several parts, and which the Greeks and Romans practised in their architecture with so much success, is not perceptible in Indian architecture, as far as we are acquainted with it. It seems easy to account for this; for, although some of the existing monuments have received the name of palaces, there is little doubt of their being all destined originally for religious purposes. Hence the architects, confined to certain established routines, were not at liberty to exercise their invention and ingenuity; and even had they been so, the system of castes, in perpetuating uniformity of practice, had a tendency to repress them. Again; scarcely any system could be conceived less likely to develop talent in ordonnance than the use of subterranean edifices, which admit of no variety of plan, no extent of elevation, and do not lead to any of those conceptions which the taste of the architect generates when he has length, breadth, and materials at his command. In the caves at Ellora some of the columns are hexagonal, without base, capital, or ornament; some square, with a long cap, like carpentry. The greater number are composed of three parts: a square pedestal, running up more than one half of the total height; a small portion of shaft, if we may so term it, crowned with a capital of strange form, of which words cannot give any definite idea. The reader may advantageously refer to Daniel's plates of these curious objects. Decoration, in architecture, consists of large and small details, which receive the name of ornaments. The larger parts are columns and similar masses. In the system of Indian decoration there is no trace of what may be called an order; but among the larger masses of decorations for support, sculptured elephants very frequently occur. In one of the temples at Ellora, for instance, there are three masses of building, on the same line, whose bases are sculptured with elephants, seen in face. Lions are also much used as objects for decoration.

These excavations date, as Mr. Fergusson has proved, from a period as early as 200 B.C.; and thus the resemblance which they present to the plan of Christian churches of the basilican type must be set down to similarity of needs producing similar architectural developments, and not, as has been somewhat unreasonably supposed, to a diabolical mimicry of Christianity on the part of the Buddhists. It was impossible that Christian buildings should be copied before they existed.

The primary idea of a Buddhist temple was that of a *tope* or pillar, which, when a monolith, is called a *lât*. These tumuli are generally without ornament, but they vary in form, being sometimes domical and sometimes shaped

like a cylinder with the roof almost flat. On the apex was the *ter*, or receptacle for the relic, of which we have already spoken when treating of the architecture of the Chinese. The umbrella which crowned the *tee* was the symbol of royalty. But while the architecture of these *topes* is altogether external, that of the temples or *chaityas* is wholly internal, no built example of these having been found. These temples Mr. Fergusson attributes, on very strong grounds, to a wooden origin, with the one remarkable exception that the pillars appear always to have been constructed of stone. This he explains from the necessity of guarding against the white ants, by 'placing some indestructible barriers between them and those parts which must necessarily be constructed of wood.'

The external treatment of the *viharas* or monasteries is supplied by remains found in Ceylon. Round the raised platform of the Thuparamya *tope* are three rows of monolith pillars, which once supported a wooden platform, on which were raised in successive stories the cells of the priests. The truth of this supposition is confirmed by the Burmese monasteries or *kinoms*, which are also raised on pillars, and which, as being made wholly of wood, explain also the absence of architectural remains in India previous to the introduction of Buddhism. 'Further proof that all more ancient buildings were constructed of wood, is found in the essentially wooden forms of the earlier cave temples, in the same character as discernible in the architecture of Persepolis, as well as in the accounts given of the temple of Solomon—facts which, if Egyptian art also sprang from a wooden type, would go far towards establishing the general prevalence of a primitive wooden construction.' (*Edinburgh Review*, January 1867, p. 120.)

The transition from the Buddhist to the Jaina creed, and again to that of Brahma, produced no new style of architecture. The Hindu temples adhered to the pyramidal form suggested by the Buddhist monasteries, terminating with the umbrella-shaped finial of the early Buddhist *topes*. The form of their gateways is invariably that of the oblong pointed roof, found in the transition example at Mahavellipore. The most remarkable features of these buildings are their large pillared halls, or *choultries*, which sometimes have as many as a thousand columns. The temples of Northern India consist generally of a great tower or *vimana*, the sides of which are curvilinear; in the centre is the cell for the divinity, and at the summit the umbrella-shaped covering. In front is attached a square *mantapa* or porch, with a door on each face, but without any other opening.

ARCHITECTURE, Moorish or Saracenic.—When the victories of the Arabians had extended their empire from Constantinople to the confines of Spain, the magnanimity of their leaders, and the brilliant talents of their caliphs, raised the nation to a pitch of glory and power which exhibited itself in some very extraordinary productions in the architectural art. In Africa

ARCHITECTURE

and in Spain, where their empire became firmly established, the edifices they erected sufficiently prove with what success they cultivated the arts and sciences.

We do not, in the narrow limits of such an article as this, think it necessary to extend any inquiry into the earliest works of the Saracens, such as the original Mosque of Omar, built in 640. Neither of that nor of other of their works (few indeed in number) have we sufficient historical evidence to compare them with the

architecture of the period in other countries; but we proceed at once to that period when some of its most distinguishing features were such arches as are here exhibited.

The Mosque at Cordova was begun by Abdalrahman, the second king of Cordova, and finished by his son towards the end of the eighth century. Its plan is a parallelogram of 600 feet by 400, formed by an embattled wall with counterforts also embattled; the height of this wall varies from 35 to 60 feet, and its thickness is 8 feet. This large quadrangular space is divided internally into two parts; viz. a court, 200 feet long by the length of the edifice, and the mosque itself, which is about 400 feet square. The mosque consists of 19 aisles, formed by 17 rows of columns, from south to north, and 32 narrower aisles, from east to west. Each of these aisles is 16 feet wide, from north to south, by 400 feet long; the width of them in the opposite direction is less. Thus the intersection of the aisles with each other produces 850 columns, which, added to the 52 columns of the court, form a total of near a thousand columns. Their diameter is about a foot and a half, and their mean height about 15 feet, and they are crowned by capitals of a Corinthian or composite species. These columns, which have neither socle nor base, are surmounted by arches from column to column. The ceilings are of wood painted, each range forming on the outside a small roof, separated from those adjoining by a gutter. One of the most striking effects of the edifice is produced by the beautiful marbles of which the columns are composed. It seems probable that the larger portion of these columns were procured from the Roman ruins in the city; an opinion which is strengthened by their being without bases, or with such as are ill suited to the style of the columns or capitals. In the commencement of the sixteenth century great changes were made in this mosque, for the purpose of converting it into a Christian church; these, it is said, ruined the original effect, but enough is left to indicate what it anciently must have been. It is always considered as one of the earliest Moorish buildings in Spain. The decorations throughout are in stucco, painted of different colours, and occasionally gilt, in imitation of Byzantine churches. One cannot doubt that its architects

were well acquainted with the Byzantine architecture, in which the walls, the arcades, the pavements, in short all the parts, were covered with paintings; and it is clear that the Arabians, who really had invented no architecture of their own, spreading themselves in those countries wherein the arts had been established, were thus led to a trial of imitating the old masters.

The Alhambra, at Granada, is perhaps the most curious and interesting Moorish edifice in Spain. It served the double purpose of palace and fortress, and is situated on the summit of a rock that commands the town. According to travellers who have described this edifice, the visitor may here fancy himself in a fairy-built dwelling. After passing the principal entrance, he arrives at two oblong courts, one of which is called the court of the lions, and is celebrated in Arabian history. A portion of the section of this court is given below. Round these two courts, on the ground floor, are disposed all the apartments of the palace; those for state look out towards the country; the rest, cooler and more retired, have small openings for light under the interior porticos, the whole of which are decorated with painted stucco, porcelain, and the most valuable marbles. On a neighbouring hill is another palace, called the Generalife: its ruins show that it was inferior to the Alhambra neither in size nor splendour. It is precisely in the same taste, and the details are similar, proving that the two edifices are contemporaneous.

Surprising as the works we have just named must be considered, we do not discover in them that real grandeur which exists in the works of the Egyptians, the Etrurians, the Grecians, or the Romans. The mode of construction, though sufficiently durable, is not scientific, as respects the working of the materials. Brick was the material most in use; the masonry, where employed, is covered with a coating of stucco, of which the painting in different colours is a great source of the admiration these buildings excite. The domes which crown their apartments are neither lofty nor large in diameter, neither do they exhibit great mechanical skill. The Moorish architects seem to have had no notion of raising vaults from lofty piers. In the mosque at Cordova, the span from pier to pier would have been less than 20 feet, to vault which would not have required very

ARCHITECTURE

extraordinary skill; yet here we find timber ceilings throughout. The use of orders seems to have been unknown to them; they employed the antique columns which they found ready to their hands, or rude imitations of them, without any apparent acquaintance with the types from which they were derived, their principles or proportions. Hence their columns may be more appropriately termed posts. In the forms of Moorish architecture we do not discover a character of originality arising out of local causes. The Arabians had wandered far from their country, in which they had never cultivated the arts; their architecture was, therefore, necessarily formed upon models which were before them, such as the degenerated Roman and Byzantine. The form of their arcades is confined to this style of architecture. They may be divided into two classes, both of them vicious in construction, from not affording the necessary resistance to thrust near the abutments. In masonry, failure would follow such forms, if practised on a large scale; but where arches are formed of brick, the large surface of cement used, if it be good and the centres not struck until the cement is set hard, allows great caprice in their forms. If the pleasure—we might almost use the word sensuality—of the eye be the sole object, it cannot be denied that success attended the efforts of the Arabian architects of Spain. The embroidery and painted draperies of the East appear to have been transposed to their architecture. The variety and profusion with which they used their ornaments, moreover, give their masses the appearance of a congeries of painting, incrustation, mosaic, gilding, and foliage. Much, perhaps, of this was induced by the law of their religion, which forbade the representation of animals or the human figure. It cannot be denied that in this profusion of ornament we find the details beautifully executed, and some of their forms extremely fine; and the mode of piercing domes for light, which they practised by means of starlike openings, is attended with an almost magical effect.

ARCHITECTURE, Mexican.—The temples and other public edifices of Mexico do not appear to have deserved the high praises which Spanish authors have bestowed upon them. The great temple of Mexico, the most celebrated in New Spain, as far as can be gathered from the obscure and inadequate descriptions of it, has been represented as a magnificent building, raised to such a height that the ascent to it was by a flight of 114 steps; yet it was but a solid square mass of earth, faced partly with stone. Its base on each side extended ninety feet: it decreased gradually as it advanced in height, terminating at top in a quadrangle of about 30 feet, whereon were placed a shrine of the deity, and two altars on which the victims were sacrificed. All the other celebrated temples of New Spain resembled that of Mexico. The great hillock at Cholula, to which the Spaniards have given the name of temple, is not approached by steps,

nor has it any appearance of stone. Perhaps it has never been more than a natural eminence of the ground.

The Spanish historians lead us to suppose that the palace of the emperor and the houses of the nobles exhibited some elegance of design and convenient arrangement: we have, however, no vestiges of these remaining, and, from the mode in which Cortes conducted the siege of Mexico, it seems likely that all the monuments of any importance were destroyed. Still, as at the period when Robertson wrote his *History* only two centuries and a half had elapsed, it seems impossible that in so short a time edifices of importance should have left no trace of their existence.

ARCHITECTURE, Roman.—It can scarcely be said that the Romans had an architecture peculiar to themselves. That which we understand by the name is a modification, some call it a debasement, of the architecture of the Greeks. But, although they thus adopted a foreign form of ornamentation, they possessed a genuine architecture, which by borrowing from others they practically destroyed; and this was the architecture of the arch. Whence it came to them, is a question which we are not called upon here to answer; but the fact remains that, where they abstained from Greek decoration, their buildings exhibited the principle of arched construction carried out with a massiveness and strength which have rarely been equalled. It may possibly have been derived from Etruria; it may have been permanently established by an Etruscan dynasty in Rome, but it is quite certain that Etruria did not derive her architecture from Greece. But whether the Cloaca Maxima and other great Roman works give evidence of a great Etruscan dynasty or not, the fact remains that the arch became the principle of all genuine Roman construction. Hence the assertion that Christian architecture may be traced directly to the Greek must be taken with a qualification; and it becomes of the greatest importance for the clear understanding of subsequent architectural history to bear in mind that the distinguishing characteristic of the former was derived from the principle, the use of which Roman architects for so long a time did their utmost to conceal. Without a struggle, Rome submitted herself to the intellectual yoke of the Greeks. 'In those instances where the skeleton of a building is Roman, she did no more than foist on them a system of decoration entirely unsuited to its new application, and which disguised or concealed all that was great and splendid in her architecture. Where with Greek detail she unites their general design, the buildings are not, strictly speaking, to be considered Roman at all. She sacrificed, in fact, for the sake of foreign elegance her native sources of strength and grandeur, and cramped a constructive genius, which might otherwise have astonished the world with a more genuine and stupendous architecture of the arch than it has ever yet beheld. The capital and entablature of Greece were not only

features alien to her art, but fatal obstacles to any real display of her powers; nor could she retain them but at the expense of an absurd incongruity and a frequent concealment of her real construction. And when, having filled the world with the vast structures of her spurious art, she fell before the inroads of Northern barbarians, her architecture became in their hands the source of illimitable beauty and grandeur only by being gradually stripped of the ungainly and cumbersome garb with which she had so studiously concealed her living powers. Greece therefore bequeathed to Rome a number of decorative features; from Rome Christian architecture derived its essence and its life. The forms of Greek art could never have given birth to any style presenting a really different character but for their accidental association with a foreign construction, while the architecture of Rome must have issued in a more magnificent development, had that of Greece never come into existence; nay, it would have done so perhaps with greater certainty and rapidity.' (*Edinburgh Review*, January 1857.)

The necessary materials are wanting to enable us to follow up historically the state of the art during the ages of the republic. There is scarcely the vestige of a ruin of the period; it is, however, easy to form, either from the political state of the times, or from the encouragement given to the other arts, and especially to literature, some idea of the extent to which the architecture of the Romans flourished. The conquest of Greece by the Romans brought to their city not only an importation of works of art, but the artists themselves. In architecture, however, the Romans at this time had erected monuments of such dimensions as were beyond the means of the little and separated states of Greece. The new state of things brought to its aid all that it needed. The great use which at this period was made of the Corinthian order, is one of the proofs of the public and private wealth. From the time of Augustus we see the extent to which richness of detail was carried. A small portion of the Baths of Agrippa, known to us under the name of the Pantheon, enables us to appreciate the art of this period, though it is now despoiled of the bronzes of its pediment, its gilt caissons, and the profusion of sculptures that adorned it. In the time of Augustus, Rome was not only the capital of the world, but the world itself; it possessed within itself all the food that was necessary for the nourishment of the art. Rome now began to raise monuments of a description unknown to the Grecians—triumphal arches, baths as large as cities, immense porticos, amphitheatres, and naumachies. The marbles of all the quarries of the then known world were almost exhausted in supplies, and even Egypt furnished the city with means of adding to the general magnificence. Applied to such new species of edifices, it would have been indeed surprising if architecture had preserved its original Greek purity. It was the medium for satisfying a vanity which knew

no bounds, and was ultimately obliged to gain its end more by effect than purity, by richness and exuberance of ornament rather than by harmony, and by grandeur of lines rather than by beauty of forms.

The luxury in art induced by the sculptor added to the number of different combinations in the Corinthian capital: this was carried to an excess which in the end produced a new order, known by the name of the composite. Thus, Roman architecture having, says Quatremère de Quincy, exhausted all the resources of richness guided by taste in the use of ornaments, throws aside all sobriety, sacrifices the whole to details and accessories, covers all parts of the surface without distinction, loads the different members with ornaments and sculptures, like a person who, to decorate a piece of cloth, covers it entirely with embroidery.

We close this article with a few remarks on the Doric order. This, in Greece itself, at the time of her subjugation, had begun to be affected by change. It had lost much of the primitive simplicity of its character and the severity of its principles. The various wants in edifices less simple in plan, a taste for elegance and richness which was found in the other two orders, tended to modify its forms and profiles. Thus, in the portico of Augustus at Athens, it was strangely changed in appearance. In Rome it was adopted with proportions still more slender, and an aspect infinitely less severe.

Architrave (made up from the Greek ἀρχα, to rule, and the Latin traba, a beam). The lower of the three members of the entablature of an order, being, as its name imports, the chief beam that is employed and resting upon the columns. A French writer has styled it the foundation of the head of an edifice. The architrave sometimes receives the name of Epistylum, from the Greek words ἐπί, upon, and στῆλος, a column.

Archives (Lat. archivum, from the Greek ἀρχῆον, a senate-house). The repositories of the public records of a state or community: sometimes the records themselves are so called.

The English archives have been in the course of the last few years gradually removed from the various depositories in which they had hitherto been kept, and accumulated in the Public Record Office, Chancery Lane, under the superintendence of the Master of the Rolls. In the twenty-fourth annual report of the Deputy Keeper of the Public Records (1863), will be found at p. iii. a table comprehending the classes of public muniments which that office now contains. And in the twenty-fifth annual report, p. xxi., will be found a list of 'Records not yet received into the Public Record Office,' chiefly on account of insufficient accommodation for the present.

Archivolt. In Architecture this term is applied to express the ornamented band of mouldings round the voussours, or arch-stones, which terminate horizontally upon the impost. The archivolt is decorated analogously with the

ARCHLUTE

architrave, which it may be said to replace in arcades, or in a series of arches.

Archlute. A double-stringed theorbo, for the bass parts, and for accompanying the voice. It had fourteen notes, and considerable power. Handel employed it in many of his operas.

Archon (Gr. *a ruler*). The title of the chief magistrate of Athens. The office was originally instituted, it is said, on the death of Codrus, the last king of Athens, and was vested in one person who enjoyed it for life, and was succeeded by his son. Its duties were those of a limited monarchy, accountable to the assembly of the people; its duration was afterwards limited to ten, six, and, finally, one year, when its functions were divided among nine persons, taken at first by suffrage, and afterwards by lot, from the nobles. One was chief among them, and was called Eponymus, or naming Archon, because the year was distinguished by his name. The second, or king Archon (*Βασιλεύς*), exercised the functions of high priest. The third, or Polemarch, was originally the chief military commander. The other six were called Thesmothetæ, or setters forth of the law, whose duties consisted chiefly in receiving informations and bringing cases to trial in the courts, and in an annual review of the whole body of laws, for purposes of amendment or abrogation. The exclusive right of the nobles to this office was taken away by the measures of Cleisthenes, who threw it open to the people at large. See especially Boeckh's *Public Economy of Athens*.

Arco-graph (Lat. *arcus, a bow, γράφω, I write*). A drawing instrument for describing arcs of circles, or other curves, without centres.

Arctic (Gr. *ἀρκτικός*, from *ἄρκτος*, the bear). An epithet given to that part of the heavens in which are situated the constellations of the Great and the Little Bear. **Arctic Pole**, the north pole of the heavens, or the northern extremity of the axis of the diurnal motion. **Arctic Circle**, in geography, denotes a small circle of the sphere parallel to the equator, and 23½ degrees from the north pole. At this latitude, the sun, at the summer solstice, comes exactly to the horizon at midnight, without descending below it. The corresponding circle in the southern hemisphere is called the *Ant-arctic*. The arctic and antarctic circles separate the frigid from the temperate zones.

Arctic Current. The current thus named is considered to originate in the ice of the Arctic seas, whence it runs along the eastern shore of Greenland and round Cape Farewell to the western shore of Greenland in N. latitude 66°, when it turns southward, forming the *Hudson's Bay Current*. Thence it passes between the Bank of Newfoundland, and meeting the Gulf Stream, crosses it as an under current flowing into the Caribbean Sea. Another portion passes along the coast of North America and reduces the temperature of the land. The Arctic current, which is cold, replaces the warm water removed by the Gulf Stream.

Arctic Ocean. The portion of the great

ARE

ocean contained within the Arctic circle. The area is estimated at between three and four millions of square miles, a very large part of which is covered with ice during the greater part of the year. The lands of Europe, Asia, and America approach by various promontories, and are almost connected by several chains of islands in this ocean, but there is now known to be open water at some parts of some seasons, connecting the Pacific with the Atlantic. The land does not appear to reach the north pole in any part, nor is the elevation of the Arctic land very great. In this respect the Arctic is very different from the Antarctic circle, and the climate of the North temperate zone is quite distinct from and much milder than that of the South temperate zone under similar conditions.

Arctium (Gr. *ἄρκτος, a bear*). A native Composite plant, forming a coarse troublesome wayside weed, with large rhubarb-like leaves, and burr-like flowerheads. It is called Burdock, and medicinal virtues have been ascribed to it. The common species is *A. Lappa*.

Arctizite. Wernerite. [SCAPOLITE.]

Arctomys (Gr. *ἄρκτος, bear, μῦς, mouse*). The name of the subgenus of *Rodentia*, or gnawers, including the marmots.

Arcturus (Gr. *ἄρκτοῦρος*). A star of the first magnitude in the constellation of Bootes, designated in the catalogues as *α* Bootes. It has a sensible proper motion.

Arquation (Lat. *arquat*). An obsolete term for the mode of propagating trees by layers, the shoots being bent.

Ardassines. A very fine kind of Persian silk.

Ardea (Lat.). The name of a Linnæan genus of *Grallæ*, or wading birds, characterised by a straight, sharp, long, subcompressed bill, with a furrow extending on each side, from the nostrils to the apex of the bill. The genus was subdivided by Linnæus into the *Cristata*, corresponding to the modern genus *Anthropoides*; the *Grus*, or cranes; the *Ciconiæ*, or storks; and the *Ardeæ*, or herons; which latter have been subsequently subdivided into *Ardea*, or herons proper; *Nycticoracæ*, or night-herons; and *Botauri*, or bitterns.

Ardent Spirit. [ALCOHOL.]

Ardisiaceæ (Ardisia, one of the genera). Exogens, which might, without much inaccuracy, be termed woody primulaceous plants. They form herbs and trees in warm countries, and have a succulent fruit; but they really differ in scarcely any positive point of structure from *Primula* and its co-ordinates. The group is now more usually called *MIRSIACÆ*: which see.

Are. The modern French measure of surface, equivalent to 100 square mètres. Its multiples are called decare, hectare, chilare, miliare, &c., equal respectively to 10, 100, 1,000, 10,000, &c. ares; its sub-multiples are termed deciare, centiare, miliare, &c., equal respectively to $\frac{1}{10}$, $\frac{1}{100}$, &c. of an are. The hectare is the term most frequently used and,

AREA

compared with English measure, 1,000 acres are very nearly equal to $404\frac{1}{2}$ hectares. [ACRE.]

Area (Lat.) In Embryology, certain definite spaces which successively arise in the germinal membrane are so called: thus the opaque spot produced by an accumulation of cells and cell-nuclei is called 'area germinativa,' or germinal area; the clear space which subsequently appears in its centre is called 'area pellucida;' and the outer part of this space, where the blood-vessels are first formed, is called 'area vasculosa.'

Area. In Mathematics, *quantity of surface*; the term, however, is usually restricted to plane figures. In measuring areas the unit is the area of a square described on the unit of length: the *number* of such unit squares which, taken together, cover the same quantity of surface as a given figure is the area of the latter. Hence the word *quadrature*. A triangle being half that of a rectangle having the same base and altitude, is equal to half the product of the lengths of its base and perpendicular. The area of any rectilinear figure is found by dividing it into triangles. The area of a figure bounded by a curve is found by the integration of $y \, dx$, where x and y , the rectangular co-ordinates of any point of the curve, are expressible as functions of a single variable by means of the equation to the curve. [QUADRATURE.] Practically the area of such a figure is found by first constructing a rectilinear figure of, approximately, the same area. [SUBDIVISION AND OFFSET.] Mechanically, the area of any plate or disc of uniform density and thickness is found by dividing its *weight* by that of the unit square cut out from the same plate.

Areæ. In Entomology, the larger longitudinal divisions of the wing: they are termed costal, intermediate, and anal, according to their relative position.

Areca (Areec, the Malabar name). An East Indian Palm tree, whose nuts, folded in the leaf of the *Piper Betel*, and mixed with a little lime, are chewed by the natives of the countries bordering on the Indian Archipelago as a stimulating narcotic.

Arena. A Latin word, signifying in its original meaning sand; but applied in a secondary sense to that part of the amphitheatre where the gladiators fought, which was covered with sand; the word is sometimes applied to the whole amphitheatre, or to any place which is habitually resorted to by combatants.

Arenaceous (Lat. arenaceus). That which possesses the properties of sand; it is used with reference to certain descriptions of stone which have the texture of loose friable varieties of sandstone cemented by some extraneous matter.

Arenaceous Rocks. Rocks in which sand forms a principal ingredient. Loose and uncompacted sands are also called in geological language arenaceous rocks, and are classed with sandstones.

Arenaria (Lat. arena). A genus of wading

ARGAND LAMP

birds, wanting the hinder toe: of this genus there is but one British species—the Sanderling. In Botany, the name given to a small genus of *Caryophyllaceæ*.

Arenation (Lat. arena). The cure of diseases by sprinkling hot sand upon the body.

Areola (dim. of *area*). The ring or margin which surrounds the pustule of small and cow pox.

Areolæ. In Entomology, are smaller spaces into which the wing is divided by the nervures: they are termed basal, middle, and apical, according to their relative position.

Areolar Tissue. In Anatomy, a term synonymous with CELLULAR TISSUE, which see.

Areolate. In Entomology, divided into small spaces, or areolations.

Areolation means any small space, distinctly bounded by something different in colour, texture, &c. The spaces of parenchyma, which in leaves are bounded by veins, are called areoles or areolations.

Areometer, or **Aræometer** (Gr. *ἀραιός*, thin, and *μέτρον*, measure). An instrument for measuring the density or specific gravity of fluids. [HYDROMETER.]

Areopagus. The chief court of judicature at Athens: so called because it met in a hall on an eminence, called the Hill of Ares ('*Ἀρειος πάγος*'). This court, which was of very early origin, was raised to the high character it afterwards enjoyed by Solon, who appointed that it should consist of the archons who had undergone with credit the scrutiny they were subject to at the expiration of their office, and added to its jurisdiction in cases of wilful murder, wounding, and arson, extensive powers of a political and censorial nature. These powers were much reduced by the measures of Pericles and his partisans. For the character and extent of the changes so introduced, see Thirlwall, *History of Greece*, iii. 24, and Grote, *History of Greece*, part. ii, ch. xlv.

Arendalite. A variety of lime-and-iron Epidote, from Arendal in Norway.

Ares. In Greek Mythology, the name of one of the Olympian gods, who in some versions of the myth is a son of Zeus and Hérè. In the *Iliad*, he is represented as of huge size, his body covering seven plethra; in the lay of Demodocus, in the *Odyssey*, he is the lover of Aphrodite. The Romans identified him with their god Mars. [MARS.]

Arethusa (Gr. *Ἀρέθουσα*). In Mythology, one of the Nereids, who gave her name to the famous fountain in the island of Ortygia, near Syracuse.

Arfvedsonite. A black, opaque variety of Hornblende, containing a large proportion of iron, and also soda, found in Greenland and Norway. Named after the Swedish chemist Arfvedson.

Argand Lamp. The application of a circular wick to oil lamps, so contrived as to allow of a current of air both inside and outside, was originally patented by a person of the name of Argand: the contrivance constitutes an important

ARGEL

epoch in the history of the improvement of lamps; by it the amount of light derivable from a given quantity of oil was enormously increased. The same principle is applied to gas burners. [LAMP.]

Argel or **Arghel**. The Egyptian name of the leaves of the *Cynanchum oleosum*, now called *Solnostemma Arghel*, which are mixed with senna leaves.

Argemone. A small genus of *Papaveraceae*, sometimes found with the aspect of thistles and the flowers of poppies. *A. mexicana* is a yellow-flowered species, whose seeds are emetic and purgative, and have been used as a substitute for ipecacuanha.

Argent (Fr. from Lat. *argentum*, *silver*). In Heraldry one of the metals employed in blazonry: it is equivalent to pearl among precious stones, Luna among planets. In engraving it is represented by a plain surface.

Argentina. A Linnæan genus of abdominal fishes, belonging to the *Scymon* family; characterised by a small mouth, without maxillary teeth; the tongue armed with curved teeth; and a transverse row of small teeth on the vomer; branchiostegal rays, six. The argentines rank in the order *Malacopterygia*, or soft-finned fishes of Cuvier. The name is derived from the silvery glistening appearance in the scales of these fishes.

Argentine (Lat. *argentum*, *silver*). A kind of carbonate of lime with a silvery-white lustre, and a slaty structure.

Argentite. A name for sulphide of silver or Silver-Glance.

Argentometer. A graduated tube used for ascertaining the amount of silver in a solution by the admission of a definite bulk of chloride of sodium solution.

Argillaceous (Lat. *argilla*, *clay*). That which has the properties of clay. Some of the limestones are said to be argillaceous when they contain as much as 10 or more per cent. of clay in their composition: some of the ores of iron are also said to be argillaceous when that ingredient is present in marked proportions. The presence of clay generally communicates a conchoidal fracture to the ore, or the mineral.

Argillaceous Rocks. Rocks of which CLAY is the prevailing ingredient. Not only clay in the ordinary sense of the word, but SHALES and SLATES come under this description, and will be found described under separate headings. Many argillaceous rocks contain other minerals. Thus, clays mixed with sand form loam; with limestone they form marl; with carbonate of iron they form clay-iron-stone.

Argo. So called from the mythical ship Argo, a very extensive southern constellation, usually divided into four: Argo, Argo in Carina (in the keel), Argo in Puppi (in the stern) and Argo in Velis. A great part of the constellation is invisible in our latitude; it has one star of the first magnitude, Canopus.

Argol. The tartar of wine.

ARICINA

Argonaut, **Argonauta**. Applied by Linnæus, in the singular number, to the testaceous cephalopod designated by Aristotle and the ancients Nautilus, and commonly called at the present day the Paper Nautilus, from the fragile nature of the boat-like shell in which the inhabiting cephalopod occasionally floats on the still seas of the warmer latitudes. Many modern naturalists limit the application of the term argonauta to the shell, supposing that its true constructor is yet to be discovered, and that the cephalopod which has hitherto been exclusively found in it, is a parasite. [OCTUPOD.]

Argonauts. In Greek Mythology, the name given to the chiefs who accompanied Jason in the ship Argo on his expedition to Colchis, to recover the golden fleece of the ram, which had borne Phryxus from Orchomenos to the palace of Æetes. For an analysis of the myth see Grote, *History of Greece*, vol. i. Part i. ch. 13.

Argument (Lat. *argumentum*). In Astronomy, denotes the angle or quantity on which a series of numbers in a table depends. For example, suppose a table were formed showing the amount of horizontal refraction at every degree, &c., of altitude; then the altitude would be termed the argument of the refraction; and the table is said to be entered with the argument.

ARGUMENT. In Logic, an expression in which, from something laid down as granted, (i.e. the premises), something else (i.e. the conclusion) is to be deduced. In ordinary discourse, the word is very often used for the premises alone, in contradistinction to the conclusion; e.g. 'the conclusion which this argument is intended to establish, is, &c. &c.' It is also sometimes employed to denote what is, in strictness of speech, a *course* or *series* of arguments: it is in this sense that we speak of 'Warburton's argument to prove the divilegation of Mo'. The word is also frequently used to express what may be properly called a disputation: i.e. two trains of argument opposed to each other, as when it is said that A and B had a long argument on any subject, and that A had the best of the argument. (Vide Whately's *Logic*, p. 300.)

ARGUMENT. In Mathematics, the term argument is often used to denote the independent variable upon whose value that of a function depends. [ELLIPTIC FUNCTIONS.]

Argyllite. A mineral lately discovered by Mr. Lewis Thompson, in very small quantities, on a nickel mine on the estate of the Duke of Argyll at Inverary, and near Fowey in Cornwall. It is a compound of lead, vanadium and sulphur, consisting of 60.8 per cent. of lead, 20.5 vanadium and 17.7 sulphur. The colour resembles that of Galena, with considerable lustre, and it occurs in minute rhombic dodecahedrons with a specific gravity of 6.04.

Argynnis. [RISHIS, THE SEVEN.]

Arictina. An alkaloid discovered in 1829, by Pelletier and Coriol, in a bark from Africa, resembling a species of cinchona.

ARIADNE

Ariadne (Gr.). In Greek Mythology, a daughter of Minos, king of Crete, who, when forsaken by Theseus, at Naxos, became the wife of Dionysus. The name of her mother, Pasiphaë, like that of Telephassa, the mother of Cudmus, connects the myth with the great body of solar legends. (Max Müller, *Comparative Mythology*; Cox, *Thebes and Argos, Introduction*; Bréal, *Hercule et Cacus*.)

Arians. The followers of the theological opinions of Arius, a presbyter of the church of Alexandria in the fourth century, who denied the equality of the Father and Son, and is generally considered as the author of a system which continued, under various modifications, to exercise the most extensive influence upon the Christian world of any heresy of ancient times. It was in the year 319 that these views were first promulgated at a meeting of the clergy of Alexandria; and their author, after some delay, was excommunicated by the patriarch Alexander. The progress, however, which the opinions continued to make, excited, after a few years, the notice of the emperor Constantine, who addressed a letter to Alexander and Arius jointly, in which he attempted to attain the object for which on other occasions he resorted to more violent methods, that of reconciling the conflicting parties upon whatever basis, and securing harmony at all events. At the earnest desire, however, of the orthodox party at Alexandria, he convened the general council of Nicea, which assembled in the year 325, and proceeded to institute a full investigation into the matter in dispute. On this occasion the Nicene creed was drawn up, in which the clause which principally affects this subject is the assertion of the consubstantiality of the Son with the Father, or the Homousion. This the Arians would not concede. A middle party arose under Eusebius of Nicomedia, who proposed, but without effect, the term Homoiousios, asserting, not the identity, but the similarity of substance. This, which is generally denominated the Semi-arian scheme, satisfied neither the Catholics nor the Arians, who from their rejection of it acquired the title of Anomoioi. The Catholics triumphed, and their opponents submitted to the decree of the emperor which required them to acknowledge the creed propounded for their acceptance. From this time, according to some writers, the Eusebians became a mere political party, who endeavoured to preserve the favour of the prince, for which they had already made the greatest of sacrifices, by a repetition of similar unworthy arts. At this period another Eusebius, the courtly bishop of Cæsarea, and celebrated historian of the Christian church, became one of the leaders of this branch of Arianism. His talents and ingenuity are represented as of singular service to the cause of the heretics, by inducing the emperor, after some delay, to command the restoration of Arius to the church of Alexandria, and the banishment of Athanasius. A day was appointed, upon which Alexander, the aged bishop, should admit the still suspected heretic

ARISTOCRACY

to the holy communion: his protestations of orthodoxy were such as to satisfy the prelate that God only could discover his real sentiments, and he solemnly declared that in His hands he left the matter. In the midst of the fears and scruples of the one party, and the anticipated triumph of the other, the proceeding was suddenly terminated by the death of Arius, an event in which the Catholics discovered a signal interposition of God, but which the heretics confidently ascribed to assassination by poison.

Aries (Lat. *the Ram*). The first constellation of the ancient zodiac. Aries also denotes the first sign or the first 30 degrees of the zodiac; the first point of Aries being the point in which the equator intersects the ecliptic, and from which the longitudes are reckoned. In ancient times the signs and constellations of the zodiac coincided; but owing to the precession of the equinoxes, the twelve signs go backward among the constellations, at the rate of about 50" annually, and the first point of Aries is now situated in the constellation Pisces.

Aries. In ancient Military Science, the Latin name of the battering ram, an instrument with an iron head used to batter and beat down the walls of besieged places.

Arika. A spirit made from fermented milk.

Aril (Arilla, in Low Lat., a piece of red cloth). In Botany, a membrane, either fleshy or otherwise, originating from the placenta, and growing over a seed either partially or entirely. Instances of it occur in the Nutmeg, where it constitutes mace; and in the *Phonynus europæus*, where it is a red succulent membrane. It is remarkable that this part, the use of which is unknown, never appears till after the young seed is fertilised.

Arioso (Ital.). A term sometimes applied to a short solo in an oratorio or opera, somewhat in the style of an air, but not so long.

Aristocracy (Gr. *ἀριστοκρατία*, from *ἀριστος*, the best, and *κρατέω*, to govern). According to the acceptance in which the word is used by ancient writers, a government in which all the best citizens of the state, i.e. those excelling either in hereditary distinction or in wealth, ruled their fellow-citizens. When the power was in the hands of a small class of these, who had acquired it by chance or usurpation, such a government was said to be an oligarchy. Thus aristocracy is enumerated by Aristotle among the distinct forms of government; oligarchy is only mentioned as a perversion of aristocracy: and the distinction as taken by him is, that in an aristocracy the governors rule for the public good, and in an oligarchy for their own. In modern times, those governments have usually been termed aristocratic in which a small privileged class of noble or wealthy persons either governed absolutely, or shared the government in various proportions with the sovereign or with the people. Thus the Republic of Venice presented the purest example of an aristocracy among the older governments of Europe: while the government of the United Provinces, before the French Revolution, might

ARISTOLOCHIA

also be cited as an instance of an aristocratic commonwealth; and Great Britain of a monarchy tempered by aristocracy. In a stricter sense, however, the word has been used by modern speculative politicians to signify any government in which 'a minority of adult males' constitute the ruling class. In this sense, the government of France, that of England both in respect of the House of Commons and of the House of Lords, and, in short, almost every state in which a census is adopted as the qualification of those who elect representatives in the national assembly, must be cited as aristocratic. The word aristocracy is also frequently used to signify a class of persons in the state: the wealthy and noble classes in a body, or the latter class by itself.

Aristolochia (Gr. *ἀριστολόχια*, from *ἀριστος*, best, and *λοχία*, childbirth). A genus of Exogenous plants, usually having twining stems, and one-sided, bent yellow or purple variegated flowers, the odour of which is often very offensive. They are stimulants and aromatics. One species, but not a twining one (*A. Clematitis*, the common Birthwort), is occasionally met with wild in England; a few are natives of the south of Europe, but the principal part of the genus is tropical.

Aristolochiaceæ. The natural order of which *Aristolochia* is the type. *Asarum* [ASARABACCA] is the only other common genus associated with *Aristolochia*; but there are several tropical forms. The wood of this order is remarkable for growing without forming concentric zones, although undoubtedly exogenous.

Aristolochin. A non-azotised principle contained in the *Aristolochia Serpentaria* or Snake-root.

Aristotelian Philosophy. A bare outline of the philosophy of Aristotle is all that we can attempt to give within the limits of the present article.

There is perhaps no ancient philosopher, the full comprehension of whose system requires so extensive a knowledge of the works of his predecessors in scientific research, and so careful a collation of detached passages in his own writings, which are composed for the most part in a fragmentary and unmethodical manner, and an obscure and concise diction. The latter difficulty will be the more apparent, when we state the now unanimous opinion of the learned, that the works of Aristotle which remain to us are entirely of the *esoteric* class, intended, not for publication, but to serve as notes to the oral lectures which he delivered to the more instructed of his pupils. It requires no more than a cursory glance at the titles and the bulk of Aristotle's writings, to be convinced of the comprehensiveness of his views, and the daringness of his design. He divides the whole circle of knowledge into three great provinces, *Metaphysics*, including, as its instrument, *Logic*; *Physics*, under which term, in addition to the sciences ordinarily falling under that denomination, he embraces a great portion of the philosophy of the human mind,

ARISTOTELIAN PHILOSOPHY

as the phenomena of sensation, memory, and fancy; and, thirdly, *Ethics*, or the science which treats of the conduct and duties of man, regarded both an individual and as citizen. His *Logic* is contained in his *Categoricals*, his treatise on Interpretation or the Nature of Propositions, his former and latter *Analytics*, and his eight books of *Topics*; to which may be added his work on the exposure of *Sophisms*. These form together what has been called the *Organon* of Aristotle; and seem intended as a preparatory discipline to the study of his *Metaphysics*. (See Aristotle's *Metaphysics*, iv. 3.) The *Logic* of Aristotle is, what it professes to be, an enumeration of the leading classes, or genera, to which all our notions may be referred; an account of the various methods by which we arrive at general propositions, and reason from these when formed; and a body of rules for the conduct of the understanding in going through these processes. [*LOGIC*; *CATEGORY*, &c.] *Metaphysics* is the science of being, as such; and herein is distinguished from *physics*, which considers only the modifications of being, and the changes to which they are subject. Each of the physical sciences has its own fundamental axioms, the truth of which it is compelled to assume: it is the province of metaphysics to verify these assumptions, and to discover their unity and connection. Aristotle's metaphysical system, though it may be said to owe its origin and many of its peculiarities to that of his great predecessor, Plato, yet deviates from it in many important respects. Both the one and the other admit the existence of a faculty, the sphere of which transcends the objects of sense: they differ as to the method by which this faculty is to arrive at its determinations. Plato seems to have thought, that in virtue of the necessary connection in which all conceptions stand to each other, we are able, so soon as we have awakened one idea in our consciousness, to arrive at the knowledge of all the rest. Aristotle, on the contrary, conceived all deductive science to be illusive which does not rest, for the truth of its fundamental principles, on a previous induction from particulars. Agreeably to this conviction, he begins his Ontological speculations with the consideration of the individual, as it presents itself in the world of sense. To the production of each separate existence, four causes are necessary: the material cause, the formal, the final, and the moving cause. The three latter, he seems to admit, are substantially identical, inasmuch as in Nature the end of a thing is that very thing itself in its completeness: while the moving cause may be conceived as the type pre-existing in the mind of the artificer, which is the same with the form which he communicates to the material. We should greatly misconceive Aristotle's meaning, if, as has sometimes been done, we identified his forms of things with their outward figure, or even with the notion of them apprehended by the understanding. The form

of a thing may be differently expressed, as the law of its being, the principle of life within it, which animates and gives an individual existence to the matter; which, on the other hand, without its presence, would remain a mere blank potentiality, destitute of all qualities, and therefore unintelligible and imperceptible. This distinction between matter and form reappears, under different names, in various portions of the Aristotelian philosophy, and is with him a solution of most of the difficulties in ontology and physics. He conceives it to be the only mode of explaining the possibility of a thing coming into existence, the difficulty of comprehending which had led the eclectic philosophers to deny any reality to outward phenomena. He himself conceives the universe to be eternal. With Plato, however, he strenuously asserts the existence of reason, as something immutable and universal: coeternal with, but unaffected by, the shifting phenomena of the world. He differs from that philosopher, in making the universal reason identical with God, instead of being, with its correlative being, a creation of the Divine energy.

Of Aristotle's strictly physical researches, though curious, and, in their day, instructive, this is scarcely the place to speak. In his treatises on the Soul, on Memory and Recollection, and on the Nature of Dreams, he has earned the perhaps still higher praise of having created the science of Psychology, and of having discovered the guiding clue to the explanation of our mental phenomena, in the principle of association.

The third great division of the Aristotelian philosophy, that which regards the relations of man as a 'social and political animal,' is comprised in the *Politics*, the *Economics*, the *Nicomachean* and *Eudemian Ethics*, and the books entitled the *Magna Moralia*. Aristotle regards the science of ethics as most intimately connected with that of politics. He repeatedly expresses his aversion from all speculations on merely ideal perfection; and his conviction that the practicable, under the existing circumstances of humanity, is the true object of ethical enquiry. Among the most influential of these circumstances on the conduct of an individual, is the constitution of the state to which he may belong; in the spirit, and according to the maxims of which he must act, if he would earn the praise of a good citizen. Not indeed that a good citizen and a good man are necessarily identical terms: they can only become so in the case of one who is a dutiful member of a rightly constituted commonwealth. The question necessarily arises, 'How is this perfect form of polity to be determined?' The answer is, that form of government is the best, which affords scope for the development of the best part of our nature; in other words, which produces the best men. Out of this circle, Aristotle cannot be said to have fairly extricated himself. He has in some measure approximated to a definite rule of morality in the

doctrine, that every virtue lies between two opposite excesses. It must, however, be confessed, that a certain degree of vagueness prevails in his ethical speculations: a vagueness of which he was himself conscious, and apparently despaired of satisfactorily removing. Perhaps the most valuable part of his moral writings, is that in which he discusses the much vexed question of the relation of happiness to morality. Pleasure, he determines, can never be taken as a measure of actions, inasmuch as it is the uniform concomitant of all natural action whatsoever. (*Eth. Nic.* l. x.) His *Politics* comprise a very careful review of the most celebrated Grecian constitutions, and a generalisation of the leading possible forms of government, with their various merits and defects, built on a careful induction from the great mass of varied facts and instances with which the history of his country supplied him. They are consequently invaluable, alike to the curious in Grecian history, and to the political theorist; and traces of their effects are sufficiently visible in the writings of perhaps all who have arrived at eminence in the latter department. See further, the article 'Aristoteles,' in Smith, *Dictionary of Greek and Roman Biography and Mythology*.

Among the editions of Aristotle's complete works the most important are (1) that of Aldus, the editio princeps, Venice 1496-98, 5 vols. fol.; (2) that of Sylburg, Frankfurt, 11 vols. 4to. 1584-87; (3) that of Bekker, 3 vols. 4to. Berlin, 1831. Of the *Ethics*, those of Michelet, with a commentary, 2 vols. 8vo. Berlin, 1835; and of Cardwell, Oxford, 1828, 2 vols. Of the *Politics*, those of Schneider and Götting. Of the *Treatise de Anima*, with copious notes, that of Trendelenburg. Numerous editions of the *Rhetoric* have been published in Oxford. Of his ancient commentators the best are Ammonius, Alexander Aphrodisiensis, Simplicius, and Thomas Aquinas.

Arithmetic (Gr. ἀριθμητική). The 'art of numbering' or science of number. In the ordinary and restricted acceptance of the term, however, arithmetic is the art of expressing numbers by symbols, of combining these symbols, and of applying to them the several rules of greatest practical utility.

For the history of arithmetic, the reader may be referred to the elaborate article on the subject in the *Encyclopædia Metropolitana*: here we must limit ourselves chiefly to the science in its present state.

In the expression of numbers the great advantage of our arithmetical notation consists in the fact that every symbol has a *local* as well as an *intrinsic* value. The intrinsic value of a symbol is the number it represents: the *local* value depends, *first*, upon the number of symbols used, and, *secondly*, upon the position of that symbol with respect to the accompanying ones. With respect to the second property, all systems of arithmetic are alike; the value of a symbol in any position, is as many

times that of the same symbol in the next following position as there are symbols employed. The number of symbols, one of which 0 has no intrinsic value, indicates the *scale of notation*, or rather the *radix* of that scale. Thus, in the binary scale of notation, where the symbols 0 and 1 are alone used, the number thirty-one would be expressed by 11111, for proceeding from right to left the several symbols 1 would have the values one, two, four, eight and sixteen. The successive symbols, in fact, represent the several powers of the radix (two) of the scale. Again, 110101 would express the sum of the fifth, fourth, and second powers of two increased by unity, that is to say, the number fifty-three. A *binary arithmetic* of this kind was, in fact, proposed by Leibnitz; for, although it would be inconvenient for common purposes, it has advantages when investigating the properties of numbers. Again, in the quaternary scale of notation, the symbols 0, 1, 2, 3, would suffice for the expression of all numbers. The above number, fifty-three, for instance, would now be expressed by 311; for, proceeding from right to left, the symbols here used would denote the numbers one, four, and three times sixteen respectively.

In the ordinary or *decimal* arithmetic, which had its origin, probably, in the ten fingers of the hand, and came to us from the Hindus, the ten symbols or *digits* 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, are employed, and we extend the Hindu method by writing symbols to the right of the units place to indicate tenths, hundredths, &c., taking care to separate whole numbers from fractions by a point called the *decimal point*; thus 103·46 indicates one hundred and three units, four tenths, and five hundredths.

In *duodecimal* arithmetic, which is still occasionally employed, the want of two new symbols for *ten* and *eleven* causes much inconvenience. In compound arithmetic, where with the same ten symbols we have in reality several scales of notation, the inconvenience is still greater, and the power and elegance of arithmetical computation greatly impaired.

In all these systems of arithmetic the rules of computation, though differing from one another according to the scale of notation employed, are deducible from the four fundamental ones of addition, subtraction, multiplication, and division. In fact, multiplication itself is merely an abridged method of repeatedly adding a number to itself, whilst division is a mode of ascertaining how often one number may be subtracted from another. The rules of involution, evolution, proportion, interest, discount, &c., which will be described in their proper places, are merely applications of the four fundamental rules above alluded to.

ARITHMETIC, POLITICAL. The application of arithmetic to researches connected with civil government, such as the number of inhabitants of a country, the quantity of food necessary for their consumption, the labour they can accomplish, the mean duration of life, the produce of the soil, the frequency of fires or shipwrecks,

&c. In applying arithmetic to inquiries of this sort, we have three principal objects in view; the first is to procure precise facts, the second to deduce from the observed facts the consequences to which they lead, and the third to determine the probability both of the facts and the consequences. [STATISTICS.]

ARITHMETIC, UNIVERSAL. The name given by Newton to algebra, or the calculation of magnitudes in general. The operations of ordinary arithmetic are founded on two distinct classes of principles; the first are independent of the particular signs by which numbers are expressed, the second depend on those signs. The general properties of numbers, which are independent of any particular system of notation, form the subject of universal arithmetic.

Arithmetical Complement of a number is what it wants of the next higher decimal denomination. Thus 4 is the arithmetical complement of 6, because it is what 6 wants of 10. In like manner 43, 578 and 13·46 are respectively the complements of 57, 422 and 86·54. The most expeditious way of finding the arithmetical complement is to begin on the left hand and subtract each digit from 9 except the last, which must be subtracted from 10. The arithmetical complement is convenient in calculating with logarithms.

Arithmetical Mean. The arithmetical mean of a series of numbers denotes the quotient obtained by dividing their sum by their number; thus the arithmetical mean of 1, 2, 7, 10 is $\frac{1+2+7+10}{4} = 5$. The arithmetical mean

between two numbers is equidistant from the latter. By the insertion of several arithmetic means between two numbers is meant the formation of an arithmetic progression whose extreme terms are the given numbers and intermediate terms the several means.

Arithmetical Progression. A series of three or more numbers (or fractions) each of which differs from that which precedes it by the same number and in the same manner. Thus, 3, 5, 7, &c.; 12, 10½, 9, &c. and generally $a, a+d, a+2d$, &c. constitute three arithmetical series: in the last d represents the common difference, and may be a whole or fractional, positive or negative number. Of the five elements of an arithmetical series, viz. a the first term, s the last term, d the common difference, n the number of terms, and s their sum, any three being given the remaining two are found from the formulæ $s = a + (n-1)d$ and $s = \frac{n}{2}(a+s) = \frac{n}{2}[2a + (n-1)d]$.

Ark of the Covenant. A coffer containing the golden pot of manna, with Aaron's rod and the tables of the covenant, placed under the mercy-seat, and serving as the centre of the religious worship of the Jews. It was either carried to Babylon, or destroyed on the capture of Jerusalem by Nebuchadnezzar.

Arkansite. A name given to the thick

ARMADA

black crystals of Brookite, which occur at Magnet Cove, in Arkansas, N.A.

Armada (Span. from Lat. *armatus*, *armed*). This name is peculiarly applied in English history to the fleet assembled by Philip II. in 1588, for the conquest of England. The Spaniards, with their usual inflation of language, termed it 'Invincible.' It consisted of 150 ships, carrying 2,650 guns, and having on board 20,000 soldiers, besides volunteers, and 3,000 seamen. The history of its misadventures and dispersion is well known. The best Spanish account of the transaction will be found in Herrera.

Armadillo (Span. *armed*, dimin.). A Spanish epithet, applied to a genus of small South American macronyous or edentate quadrupeds, characterised by a defensive armour of small polygonal bony plates, which covers the head, trunk, and sometimes the tail. Linnæus applied to this genus the term *Dasyus*, by which the Greeks, with more propriety, designated the hare and rabbit.

Armament (Lat. *armamentum*). A force equipped for war, naval or military. In Roman antiquities, armamenta comprehended the rigging and tackling of a ship, its sails, sail-yards, oars, ropes, &c. Hence 'Arma' sometimes denotes the sails and the rudder of a vessel. (Virgil, *Æn.* vi. 353.)

Armatoli. A kind of national Greek militia, founded in the middle ages. They were dispersed with great cruelties by Ali Pasha of Yanina, in the latter part of the last century; but at the breaking out of the revolution, they issued forth from their native fastnesses in aid of their country's liberty.

Armature. A piece of soft iron applied to a loadstone, or connecting the poles of a horse-shoe magnet.

Armenian Church. The Armenians are Christians of the Eutychean or Monophysite doctrine, which recognises only one nature in the Saviour, viz. the Divine; and the procession of the Holy Ghost from the Father only. They hold the seven sacraments of the Romish Church, and the doctrine of transubstantiation: their clergy is also divided into secular and regular. From the wide dispersion of the Armenians over the commercial regions of the East, their form of Christianity is also considerably diffused, although it appears to be strictly a national church of which none but Armenians are members. Since the war between Russia and Turkey in 1829, the place where the principal of their four patriarchs resides (Etchmiadzine), has been transferred from the latter to the former government. There is also at Constantinople, and in other parts of the Levant, an Armenian Roman Catholic Church, owing the supremacy of the Pope. There is a well-known congregation of Armenian monks on the island of San Lazaro, near Venice, who have published a variety of useful works in the language of their country.

Armenian Stone. A commercial name for Lapis Lazuli.

ARMINIANS

Armiger (Lat. from *arma*, *arms*, and *gero*, *I bear*). In Heraldry, an esquire, or one entitled to bear arms.

Armilla (Lat. a *bracelet*). In Ornithology, the coloured circle of the distal naked end of the tibia, above the tarsal joint.

Armillary Sphere. An ancient astronomical machine, composed of an assemblage of hoops or circles, representing the different circles of the system of the world, as the equator, the ecliptic, the colures, &c., put together in their natural order, and occupying their proper relative positions.

Arminians. In Theology, those who hold the tenets of Arminius, a Protestant divine, born in Holland in the year 1660. They are thus summed up:—

1st. God from all eternity determined to save all who He foresaw would persevere in the faith, and to condemn all who should continue in unbelief.

2d. Christ atoned for the sins of all mankind, but those only who believe partake of the benefit of that atonement.

3d. Man is of himself incapable of true faith; therefore regeneration by the Holy Spirit, given of God through Christ, is necessary.

4th. All good works are to be attributed to the grace of the Holy Spirit, which, however, does not force a man against his own inclination.

5th. God gives to the truly faithful the means of continuing such. With respect to the possibility of a defection from this state of grace, Arminius and his immediate followers expressed themselves undecidedly; but it came afterwards to be considered a part of the character of Arminianism to affirm the possibility.

The assertors of these opinions in Holland were vehemently attacked by the Calvinistic party, which was prevalent at the time; and in 1610 the Arminians addressed a petition to the States of Holland for protection, from which they derived the name of Remonstrants. In the year 1618, nine years after the death of Arminius, the Synod of Dort (Dordrecht) was convened by the States-General, and a hearing given to both parties. The Arminian opinions were defended by Episcopius, divinity professor at Leyden; but his side complained that they were unfairly treated, and the conditions of the discussion violated to their prejudice. They were condemned by the Synod, and treated in consequence with great severity, being forbidden to exercise the ministry in public: many of them fled to Antwerp, France, and other quarters.

From this period their opinions underwent a considerable change; and the articles above stated, which seem little different from the tenets of the Lutherans, began to be so explained as almost to do away entirely with the idea of the necessity of succour from the Holy Spirit. From hence they proceeded to reject many matters of faith, and to simplify materially

ARMISTICE

the articles requisite for salvation. They proposed to draw up such a comprehensive and liberal scheme as should embrace all Christians, with the exclusion of the Romanists. They considered it sufficient that a man should receive the Holy Scriptures as the rule of faith, and allowed each individual to interpret them for himself, only adding thereto the necessity of moral duties and good works. The Papists were excluded on the score of morality, as admitting the lawfulness of persecution.

There is no longer any particular sect to which the name Arminian is exclusively applied; but the opinions above stated are adopted in England by one branch of the Methodists, who follow therein the views of their founder Wesley, and by many individuals of the Church of England, and other denominations. The articles of the English Church have been represented by different parties as inclining both to Arminianism and Calvinism; and Whitby, and Taylor, bishop of Norwich, are among the most famous of her friends who have maintained the Arminian tenets.

Armistice (Low Lat. *armistitium*). In National Law, a truce or suspension of hostilities.

Armour (Lat. *armatura*). A term applied to those artificial means by which men either protect themselves or annoy their enemies, hence called defensive and offensive. *Defensive* armour includes those arms specially used for the defence or protection of the body, as cuirasses, helmets, &c. *Offensive* arms, or those used in attack, are of different kinds; 1. For cutting, such as the sabre; 2. For thrusting, such as the straight sword, the bayonet, pike, lance, &c.; 3. And lastly, for shooting, such as muskets, pistols, and cannon. The history of armour is identified with that of every nation; and an elaborate discussion of this subject would throw great light upon questions of mythology, poetry, jurisprudence and civil polity, and strikingly display the progress of civilisation. On this subject, the reader is referred to the work of Sir Samuel Meyrick (3 vols. 4to. London, 1824), which the student of the politics, arts, manners, and wars of antiquity and the middle ages, may consult with great benefit.

Armour-plate. 1. [IRON ARMOUR PLATE.]

Arms or **Armorial Bearings**. In Heraldry, the name given to the devices borne on shields or coat armour. Family coats of arms are divided by heralds into perfect and imperfect. Perfect are: 1. Abstract, or warranted by regular descent. 2. Terminal, belonging to the brethren of the right line. 3. Collateral, borne by brethren of the heir male. 4. Fixal, in third degree by right line of male heirs. Imperfect are: 1. Granted by the king, with a lordship. 2. The gift of a king, derived by a herald. 3. The ensign of a Saracen won in the field. 4. Heir female of close branch. 5. Arms of bastardy.

Army (Fr. *armée*). A body of men organised and disciplined for military service,

ARMY

commanded by a chief or leader, with subordinate officers in regular gradation, and supported both in time of peace and war for the preservation of internal quiet and defence against foreign aggression. An army is generally divided into a certain number of corps, each consisting of divisions, brigades, regiments, battalions, or squadrons. When in the field it is formed into lines: the first is called the vanguard; the second, the main body; the third, the rear-guard or body of reserve. The middle of each line is occupied by the foot; the cavalry forms the right and left wing of each line, and sometimes squadrons of horse are placed in the intervals between the battalions. In the history of armies we may distinguish those of three different periods: 1. The ancient armies, which from the time of Sesostris downwards underwent a series of progressive improvements under the Persians, Greeks, and Carthaginians, till they finally reached a high degree of perfection under the Romans. 2. Those of the middle ages, the offspring of the feudal system, which, however well calculated to keep alive a spirit of ferocity, opposed a formidable barrier to the revival of the military art, from their contempt of discipline and utter lawlessness. 3. Those that have existed since the invention of gunpowder and the establishment of standing armies. Since the use of gunpowder there have been seven principal periods in the history of the military art. The first extends from the early part of the fourteenth to the end of the fifteenth century. The second begins with the campaign of Charles VIII. in Italy, and extends to the commencement of the wars in the Netherlands, comprising the wars of the French, Germans, and Spaniards in Italy. The third period comprehends the great war of independence, waged by the Netherlands, in order to shake off the yoke of Spain, and extends from 1668 to the general suspension of hostilities in 1609. The fourth period comprises the celebrated Thirty Years' War, and extends from 1618 to 1648. The fifth period comprehends the wars of the French in Italy, Germany, and the Netherlands, as well as the Northern and Turkish wars, and embraces the space of 90 years, viz. from 1648 to 1738. The sixth period includes the three Silesian wars, viz. from the beginning of the first Silesian war in 1740, to the breaking out of the French Revolution in 1792. During these several periods many improvements took place in the composition and discipline of armies; but these were destined to be far surpassed in the seventh and last period, which embraces the military systems and establishments of our own times. In the organisation of the Continental armies great uniformity prevails; but as these are inseparably connected with the political condition of the people, a consideration of their character belongs to the history of these various nations, to which we must refer the reader. The British army, like those of the Continent, is divided into cavalry, infantry, and artillery,

ARNICA

and these again into regiments and brigades; but in its composition and organisation an entirely different principle is adopted. While the Continental armies are recruited by conscription, and every officer must have served as a private or a cadet, or have acquired some knowledge of the military art in a preparatory establishment, the ranks of the British army are supplied by voluntary enlistment, and commissions are attainable by any British subject within prescribed limits of age who is successful in competing for entry into, and passes through the Royal Military College at Sandhurst; or, in the case of the Artillery and Engineers, the Royal Military Academy at Woolwich. Direct commissions are also given by the commander-in-chief.

The sovereign is the actual head and chief of the army, but she delegates her power to a commander-in-chief, who has supreme command and authority in all matters of discipline. The money for the pay of the army is voted annually by Parliament, which thus renders the use of the army for purposes of military despotism impossible. The estimates are prepared by the Secretary of State for War, under whose control the expenditure of this money is placed, and who acts in conjunction with the commander-in-chief in all matters concerning the welfare of the troops.

Arnica. A genus of composite plants, on species of which, *A. montana*, the Mountain Tobacco, a native of Central Europe, possesses acrid and stimulant properties. It is a dwarf herbaceous plant with large yellow-rayed flower-heads.

Arnicae. A bitter principle contained in the flowers of the *Arnica montana*.

Arnoldists. In Ecclesiastical History, the followers, or rather partisans, of Arnold of Brescia, who in the twelfth century was the first to raise his voice against the abuses and vices of the papacy. He acquired for a time considerable influence among the lower orders, and the tumults which were raised by his supporters caused great uneasiness in Rome, which was the chief scene of his proceedings. He was finally put down by an armed force, made prisoner, and burnt by Pope Adrian IV. Certain heretical notions on the nature of the Eucharist were charged against him; but the insurrection which arose under his auspices was clearly a political disturbance, and his harangues seem to have been directed rather against the morals than the tenets of the church which he attempted to reform.

Arnoides. The *Arum* family; a synonym of *Araceae*.

Aroma (Gr.). The characteristic odour of substances, especially the strong and peculiar odours of certain plants, whence the term *aromatic*.

Arpeggio and Arpeggiato (Ital.). In Music, the sounding the notes of a chord in quick and repeated succession, so as to imitate the harp.

Arpidolite. [SPERM.]

ARREST

Arquebusade (from arquebuse, a *hand gun*). An aromatic spirituous lotion, applied to strains and bruises, but originally invented as an application to wounds inflicted by an arquebuse.

Arquebuse, or Harquebuse (Fr. arquebuse, from Low Lat. arcubagia, a *musket-stock with a bow fixed to it*). A sort of hand gun, used by infantry before the invention of the musket. The word is used very loosely in old writers for every sort of fire-arms used by infantry. Gunsmiths are still called arquebusiers in France. In the German, Spanish, and Gascon infantry of the earlier part of the sixteenth century, the pike and arquebuse men were intermixed in the same ranks. The barbarous English words hackbut, hackbuttre, which we find in military language in the reign of Elizabeth, are derived from arquebuse, arquebusier. The arquebuse is said to occur first in the descriptions of the battle of Morat in 1476. Arquebusiers on horseback are mentioned in that of the battle of Fornovo, 1494.

Arquerite. A Silver Amalgam occurring in small octahedral crystals and in arborescent forms, at the mines of Arqueros in Chili. It contains about 86 per cent. of silver and 13·5 of mercury.

Arracacha. The South American name for an umbelliferous plant, the *Arracacha esculenta* of botanists; whose fleshy sweet roots are cultivated in Columbia and Jamaica, in the same way as parsneps and carrots in Europe. The roots are of large size, and in quality, when cooked, are between a sweet chestnut and a parsnep. Attempts to introduce it into common European cultivation have uniformly failed.

Arraché (Fr. from arracher, *to snatch*). In Heraldry, the representation of a plant torn up by the roots.

Arrack (Indian). A spirituous liquor, obtained by distilling the fermented produce of rice; but other spirituous liquors are called by the same name. Arrack has a very strong and somewhat nauseous flavour and odour, derived from a peculiar volatile oil which it contains, and which corresponds with that which gives a sickly and disagreeable taste to our corn spirit.

Arraignment. In Law, the arraignment of a prisoner on a criminal charge consists in calling him to the bar, and (in treason or felony) making him hold up his hand, or otherwise own himself to be the party charged, reading the indictment to him in English, and demanding of him his plea (guilty or not guilty), and entering it accordingly.

Arras. [TAPESTRY.]

Arreey. A singular institution formerly existing in Otaheite and other Society Islands, which, it is asserted, involved infanticide for political purposes. It was first noticed by Capt. Cook, and is further described by Ellis, in his *Polynesian Researches*, vol. i. p. 311.

Arrest (Nor. Fr. arrester, Fr. arrêter, *to stop*). In Law, in execution of the command of some court of record or officer of

ARREST OF JUDGMENT

justice may take place either in criminal or civil cases. 1. For felony, and in some other particular cases, any person may arrest without warrant or precept. Arrests by public officers may be made either with or without process. Any constable, or even private person, who has a warrant directed to him from a justice of the peace to that effect, may arrest for felony or misdemeanour; and, if the warrant was given without sufficient ground, the justice is responsible. Every warrant should be under the hand and seal of a justice of peace, and specify the day on which it was made out, and state shortly the offence on which it is founded, and describe the offender. (11 & 12 Vict. c. 42.)

2. Arrest in civil cases, for debt, is either after judgment obtained or before judgment obtained (arrest on *mesne*, i.e. intermediate, process). The latter was for centuries in England the ordinary mode of endeavouring to compel a debtor to satisfy his creditor. But at the beginning of the present reign (by statute 1 & 2 Vict. c. 110) this kind of arrest was confined to cases in which the creditor shows on affidavit reasonable ground for supposing that his debtor is about to leave the country. Arrest after judgment (under the writ entitled *capias ad satisfaciendum*) subsists where the debt exceeds 20*l.*: but the Insolvent Court [BANKRUPTCY] has power to deliver the debtor on terms imposed by the court. The same court has a power of its own to grant warrants for the arrest of absconding debtors until a writ of *capias* can be procured. (Absconding Debtors' Arrest Act, 1851.) As to the freedom of Members of Parliament from arrest, see *May's Parliamentary Law*, chap. 5.

Arrest of Judgment. In Law. [JUDGMENT.]

Arria. In Architecture, the edge of two surfaces meeting each other; or the line of meeting of two planes in a sharp edge.

Arrondée (Fr. *arrondir*, to round). In Heraldry, a cross consisting of segments of a circle.

Arrow-headed Writings. [CUNEIFORM LETTERS.]

Arrow-root. The commercial name of the starch obtained by washing the grated tubers of the *Maranta arundinacea*, which it yields to the amount of twenty-five to thirty per cent. It is sometimes adulterated with potato starch, and the fraud is not easily detected; it, however, gives a disagreeable flavour and smell, like that of the raw potato, and forms a less firm jelly with hot water than when the arrow-root is genuine. Various other plants yield a similar bland starch, to which the name of arrow-root is applied in different countries.

Arsenal (Ital. *arsenale*, perhaps from the Arab. *dār ḡanah*, a place for work). In Military Engineering, an arsenal implies the place where ships of war can enter and repair any damage which they may have sustained at sea, or in action with the enemy; or where the army may resort for supplies in case it requires them. A good arsenal must then con-

ARSENIC

tain shops, or fabrics, for the repairs of vessels, with graving docks, basins, floats, &c.; it must contain the shops for making the guns or ammunition required, the gun-carriages, and the other implements of war; and storehouses for receiving these goods until they are wanted. Engineers are warmly divided as to the necessity of fortifying these establishments. England has some very complete arsenals; as also have France and Spain. Plymouth, Portsmouth, and Woolwich, may be cited as specimens of the first; Cherbourg, L'Orient, Brest, Ferrol, and Corunna, of the second of these works.

Arsenic (Gr. *ἀρσενικός*, powerful). A soft, brittle, and eminently poisonous metal, of a steel-grey colour; its sp. gr. 5.7. It volatilises, exhaling a strong odour of garlic, before it fuses, at a temperature of about 400° F., and is easily inflammable. It combines with oxygen in two proportions; and as both compounds are sour, and form salts with bases, they have been termed arsenious and arsenic acids: the former is composed of 75 arsenic and 24 oxygen, and the latter of 75 arsenic and 40 oxygen. Arsenious acid is more commonly known under the name of *white arsenic*, and is the usual state in which this poison occurs in commerce; it is obtained during the extraction of several of the metals from their ores, and is a white brittle semitransparent substance, having little taste, but is virulently poisonous. Its sp. gr. is about 3.7. It forms a dull white powder, and it is in this form that it is usually sold. When heated in the flame of a candle, it rises in a white poisonous vapour, and exhales, in consequence of its partial reduction, a strong garlicky smell. The solubility of white arsenic in water varies with its isomeric modifications; 100 parts of water at 60° dissolve about 0.95 of the vitreous, and 1.25 of the opaque acid, and at 212° 9.7 of the former and 11.5 of the latter. When these hot solutions are cooled down to 60°, 1.8 of the vitreous and 2.9 of the opaque are retained in permanent solution. White arsenic dissolves in the alkalies, and combines with the metallic oxides, forming a class of salts called *arsenites*: they are all poisonous. Of these the arsenite of potash is used in medicine, under the name of Fowler's mineral solution: it is employed in very small doses in the cure of agues, and is an effective remedy, but requires much care in its administration.

When white arsenic is taken as a poison, it produces violent spasmodic pains of the stomach and bowels, attended by a sense of heat, and constriction in the mouth and throat, an increased flow of saliva, tightness about the head, itching of the face and neck, and nausea. These symptoms are succeeded by vomiting and purging and excruciating pains; the pulse, at first full, hard, and frequent, sinks and becomes irregularly feeble, and clamminess of the skin, cold sweats, and convulsions precede death; or if the patient escape this catastrophe, it often happens that hectic fever,

paralysis, and mental and bodily debility attend him for the remainder of his days. It has destroyed the life of an adult in the small dose of two grains, and is equally fatal whether taken by the mouth or applied to a wound. After death the stomach and bowels are usually found inflamed, but often only slightly so; and it appears from Sir B. Brodie's observations, that this poison kills by some peculiar action upon the heart and nervous system. The treatment of persons thus poisoned consists in promoting the vomiting by an emetic, composed of a solution of 20 grains of sulphate of zinc in two ounces of water, aided by copious draughts of warm barley-water or gruel; but the most effective means of getting rid of the arsenic, is by the use of the stomach-pump, which, when immediately resorted to, has often saved the patient. The after-treatment requires much circumspection.

White arsenic is used in many of the arts, especially in colour-making, dyeing, and calico-printing, and in preparations for the destruction of vermin. In the small quantities in which it is sold to the public, it is directed to be coloured with soot, or indigo.

Arsenic acid is more soluble and sour, but not less poisonous than the arsenious acid. Its salts are called *arseniate*s, and the arseniate of potash obtained by deflagrating a mixture of white arsenic and nitrate of potash is occasionally used in medicine: it is the active ingredient in the tasteless ague drop.

For the means of detecting arsenic, and for the treatment of cases of poisoning by it, the reader is referred to works on chemistry, toxicology, and medical jurisprudence.

Arsenosiderite. A hydrous arsenide of lime and peroxide of iron forming fibrous concretions of a yellowish-brown or golden colour, in a manganese bed at Romanèche in France.

Arsis and Thesis (Gr. *ἀρσις*, *lifting up*, *thesis*, *laying down*). In Music, terms used in composition, as when a point is inverted or turned, it is said to move *per arsin et thesin*, that is, when it rises in one point and falls in another; properly speaking, it is the rise and fall of the hand in beating time.

Arson (Low Lat. *arsio*, *a burning*). At Common Law, signifies the maliciously and voluntarily burning the house of another. This offence is now defined and regulated in its various degrees by the stat. 24 & 25 Vict. c. 97, ss. 1—8. The subjects of arson are defined in the first eight sections of this statute, so as to include buildings of every description. Burning ships is penal under sec. 42 of the same statute; burning crops, &c. under sec. 16. The punishments vary according to the quality of the offence, the highest being penal servitude for life.

Art (Lat. *ars*). The application of knowledge or power to effect a desired purpose. The ancients divided the arts into '*artes ingenuæ*,' '*bonæ*,' or '*liberales*,' and '*artes serviles*.' Under the latter were comprehended the mechanical arts, because these were practised only

by slaves. In modern times arts are divided into fine and useful, comprising under the former those which have not utility for their direct or immediate object; such as music, poetry, sculpture, &c. (For the history and description of the fine and useful arts, see the respective articles.)

Artanthe. A genus of *Piperaceæ*, consisting of woody plants with jointed stems, and formerly included among the peppers. *A. elongata* furnishes one of the articles known by the Peruvians as *Matico*, which is applied to the same uses as cubebs. It also supplies a valuable styptic, the rough leaves having the power of staunching blood.

Artemis. [ORTOGIA.]

Artemisia (Gr.). A composite genus consisting of stimulating plants, of which Wormwood, Southernwood, and Tarragon form a part.

Arteriotomy (Gr. *ἀρτηρία*, *an artery*, and *τέμνω*, *I cut*). The opening of an artery: this operation is occasionally performed upon the temporal artery, with a view of relieving inflammatory symptoms about the head.

Artery (Gr. *ἀρτηρία*). These vessels are usually found empty in the dead body, and were supposed by the old anatomists to be air tubes; they are ramifications of the aorta, and convey the florid blood with a pulsating motion to the different organs and parts of the body. [AORTA.]

Artesian Well. A kind of well in which the water is obtained by sinking, or boring, through an upper retentive stratum to a subjacent water-bearing stratum, the entering or supply ground of which is situated at such a level as to enable the water from it to flow over the surface of the ground, at the point where the well is made. The term is only correctly applied, when the water overflows, although it is frequently used to express deep wells, sunk merely through impermeable to permeable strata; it is derived from the name of the province of Artois, in French Flanders, where these wells have long been known; they seem also to have been used from time immemorial in Lombardy and in the Adriatic provinces of Northern Italy.

About the beginning of the present century much attention was called to the subject of Artesian Wells, by the remarkable success of some operations of that description in the valley of the Thames, near Waltham and Tottenham, and in the valley of the Wandle near Merton and Garratt. At the commencement the water in these wells was found to flow over the surface, and even at the present day this continues to be the case with some of the wells in the valley of the Wandle; but the number of wells sunk through the London clay into the sands between that formation and the chalk has been so great, that the normal supply of the water-bearing stratum has not been equal to the demand upon it, and the water level has been constantly lowered of late years in the London wells, so as, in fact, to destroy their Artesian character. The same result took place

ARTESIAN WELL

in France, especially in the Paris tertiary basin, where many wells were also sunk about this period; and it was on this account that M. Arago recommended the municipality of Paris to seek a fresh source of supply, by passing through the whole body of the chalk, until the permeable strata of the lower greensands were encountered. From the levels at which the lower greensands outcropped above Paris, M. Arago inferred that the water they contained would rise considerably above the surface of the ground at Paris itself; and the result of the great experiment tried at Grenelle, under his directions, was to substantiate his theoretical reasoning on the subject. This well, commenced in 1833, was carried to the depth of 1,806 ft. 9 in.; and on February 26, 1841, the water-bearing stratum of the lower greensand was reached, whence the water rose to the height of 122 ft. above the surface of the ground at Grenelle. Since the execution of this successful boring, many attempts have been made to obtain a supply of water by similar means; but the failures have been so numerous as to induce prudent men to regard the first essay of the system of Artesian boring, in an untried district, purely as a matter of experiment. The circumstances attending the failure of the Highgate, Harwich, Ostend, and Calais wells, show that, although certain strata may outcrop all round a particular place, it by no means follows that those strata should form continuous basins under that place; so that there is no certainty of the uninterrupted passage of the water under the superficial retaining stratum. The Southampton and the Chichester wells were both abandoned before the geological conditions of those localities had been ascertained; and the results of the Brighton well prove that, in the two instances last named, a further amount of perseverance would have been rewarded. Geology, however, can only assure us of what we shall *not* find under certain circumstances; it can never tell us what we *shall* find; and therefore, until a certain district shall have been made the subject of actual experiment, it is impossible to say whether, or not, it be possible to secure in it a supply of water by means of Artesian wells. The theoretical conditions required to warrant the belief in the probable existence of such a supply are:—1st, the existence of a mass of impermeable material, surrounded by a permeable stratum, whose lowest point on the exposed surface should be above the level of the point where the well is proposed to be sunk; and 2nd, that the mass, or cubical capacity for water, of the permeable stratum should be sufficient to meet the demands upon it. These conditions have been found to exist in the Great Desert of Sahara, and no less than fifty Artesian wells had there been executed up to the month of June, 1860, which were fed by the waters falling on the exposed edges of the permeable strata of the Atlas chain, passing subsequently under the clay, and the fissured sandstones of the Desert itself. Many very important and deep

ARTICLES OF FAITH

Artesian wells have been executed in northern Germany for the purpose of bringing to the surface the brine springs of that part of Europe; and the petroleum wells of the United States and of Canada seem to be of the same technical description. The most celebrated Artesian well, recently executed, is the one at Passy, in the neighbourhood of Paris, fed from the same strata as the well of Grenelle: the Passy well is about 1,923 ft. deep from the surface of the ground; the water flows over the surface at the rate of 5,582,000 gallons per day, and rises to a height of about 54 feet above the ground. The well was bored by M. Kind of the enormous diameter at the bottom of 2 ft. 4 in.; and it has been observed that in the two cases of the Grenelle and of the Passy wells, the deliveries have been in the direct ratios of the diameters of the borings.

Arthanitin. *Cyclamin*, a bitter non-nitrogenous matter contained in the root of *Cyclamen europæum*.

Arthritis (Gr. ἄρθρον, a joint). Gouty inflammation of the joints.

Arthrodia (Gr. ἀρθρῶdia, articulation). A connection of bones in which the head of one is received into a very superficial cavity in another, so as to admit of motion in almost all directions; as in the joint between the *humerus* and *scapula*.

Arthrodiseæ (Gr. ἄρθρον). A name given to those Algae which, like *Conferva* and *Oscillatoria*, have an articulated structure.

Arthrodynia (Gr. ἄρθρον, and ὀδὼν, pain). Rheumatic and other painful affections of the joints.

Artichoke (Kharciot, the Arabic name of the plant). A thistle-like plant, called by botanists *Cynara Scolymus*, a native of the south of Europe, and now cultivated for its 'bottom,' that is, for the sake of the fleshy sweet receptacle of its flowers. The harsh hairy substance that is pulled away consists both of the hairy palææ of the receptacle, and of the feathery pappus of the ovaries. The dried artichokes, called by the French 'cœurs d'artichaut,' are the receptacles deprived of the choke and the spiny hard hairs of the involucre, blanched by immersion in boiling water and dried in the sun. Jerusalem Artichokes are quite different; they are the tubers of *Helianthus tuberosus*, and derive their name, not from the Holy City, but from a corruption of the Italian *girasole*, a sunflower.

Article (Lat. articulus). In Ecclesiastical Law, the name given to the 'first plea,' that is, the charge or indictment, in criminal cases.

Articles. In Grammar, a part of speech prefixed to substantives in order to render their signification more or less definite. [GRAMMAR.]

Articles of Faith are the particular points of doctrine which together make up the sum of the Christian belief. The various churches of Christendom, not being agreed upon all these points, have for the most part set forth their own expositions of the whole; and it is to these creeds, symbols, or confessions, that the term

articles is most commonly applied. The articles of the English Church are thirty-nine in number; the substance of which was first promulgated in forty-two articles by Edward VI. in 1553. Under Henry VIII. a committee had been appointed for the formation of ecclesiastical laws, which was renewed under his successor; and in 1551, 'the archbishop (Cranmer) was directed to draw up a book of articles for preserving and maintaining peace and unity of doctrine in the church, that, being finished, they might be set forth by public authority.' From this and the details that follow, it seems that Cranmer composed the articles in their original form, with the assistance of Ridley and others. A great similarity in thought and expression may be traced between many of the articles and the language of the Augsburg Confession: the XIth Article (on justification) corresponds with what Cranmer had previously written on the subject in private memoranda. There has been considerable question raised as to the authorities from which the XVIIth Article (on predestination) is derived; for while some persons have interpreted expressions in it according to the Calvinistic system, others have denied the justice of such interpretation, and have undertaken to show that Cranmer must have referred in the composition of the article to the writings and sentiments of Luther and Melancthon.

On the accession of Elizabeth these articles were remodelled by Archbishop Parker, who omitted four of them, introducing four new ones, and altering seventeen. These were again revised by Convocation in 1563, some alterations made, and the number reduced to thirty-eight.

The XXXIXth was restored in a final review by Parker in 1571, and then imposed on the clergy for subscription. It is remarkable that in the manuscripts and earliest editions there is one important variation in the admission or rejection of the first clause of the XXth Article, the authority of which may be considered as virtually recognising and establishing it.

Articles of the Peace. In Law, one bound before a magistrate under a penalty, with or without sureties, to 'keep the peace' for a certain time, is said to enter into articles of the peace.

Articles of War. The code of military law embodied in the Mutiny Act, which is passed each year.

Articulated (Lat. *articulus, a joint*). Literally, connected by an articulation or moveable joint; but in Botany applied to cases where the parts of plants are so slightly connected that they finally fall asunder. Thus a leaf is said to be articulated with its stalk when the two finally fall asunder. A flower-stalk is articulated in the middle when it is contracted, and finally separates there into two parts. This separation is called disarticulation. It is a curious fact that the articulation of plants uniformly takes effect across the longitudinal or woody tissue, and never parallel

with it; as in the petiole, in a stem at its nodes, in the middle of legumes and other kinds of seed vessels.

Articulates, Articulata. A term applied by Cuvier to a primary division of the animal kingdom, characterised by an external skeleton in the form of a series of rings articulated together and surrounding the body; by an internal gangliated nervous system; the ganglions being arranged symmetrically along the middle line of the body [*HOMOGANGLIATA*], and by having distinct respiratory organs.

Articulation. In Painting and Sculpture, this term indicates the moveable connection of the bones, in the representation of which the artist needs the greatest skill and knowledge of anatomy.

Artificer (Lat. *artifex*, from *ars, art*, and *facio, I make*). Lit. one who makes according to art. An artificer is one who requires intellectual refinement in the exercise of his profession, in contradistinction to an artisan, whose knowledge is limited to the general rules of his trade.

Artillery (Lat. *ars, artis*, used like *machina*, the Greek *μηχανή*, in the sense of an engine of war). This term originally signified all weapons of offence or defence, the machines employed in warfare, &c. Since the introduction of gunpowder, however, it has been chiefly confined to large ordnance, viz. cannon, howitzers, mortars, rockets, &c., with their carriages, ammunition, and apparatus of all kinds, and the 'personnel' appointed for their management.

The principal military engines of the Romans corresponding to our artillery were the ballista and catapulta, the former of which chiefly propelled stones, and the latter arrows. These engines were extensively employed in the later periods of the Republic, and under the Empire. In the middle ages, machines for the assault and defence of towns and castles were used in great numbers; among them may be named the trebuchet or trippet, the mangona or mangonel, bricola, pierrier or petrary, &c. Some of these engines were of great power, and threw missiles of as much as 300lbs. weight. Froissart tells us that at the siege of Auberoche in 1345, the Earl of Derby, by means of one of these mangonels, threw back into the town a man who had been sent to demand terms of him.

The history of the early employment and manufacture of cannon will be found in the article **CANNON**.

At first, artillery was the property of the great towns and castles, for in those times kings could scarcely afford so expensive an appliance of warfare. Later only, when kings permanently retained large armies, they became possessors of artillery of their own, and had no longer to borrow from their towns. Louis XI. of France and Charles the Bold of Burgundy, in the latter half of the fifteenth century, did much towards improving artillery, and towards the close of that century the artillery of Charles VIII. was well and carefully organised. The seventeenth century was an important epoch for

this arm. Gustavus Adolphus paid much attention to its improvement and organisation, as also did Louis XIV. of France. In the following century Frederick the Great, in the Seven Years' War, introduced horse artillery able to keep pace with rapid manœuvres; and in France, in 1732, the whole system was put on a new footing, and simplified. In our own country, before the wars following the French Revolution, artillery was distributed among the infantry in the proportion of two guns to each battalion, but a new arrangement was then introduced by which guns for field purposes were united into batteries of six pieces. This much increased the power of the arm, and the whole equipment was at the same time simplified and lightened.

Artillery as it is now employed may be classed under the heads of Field Artillery, Siege Artillery, and Garrison Artillery; its equipment is a combination of men, horses, and matériel.

Field Artillery is divided into—1. Horse artillery batteries, which act and manœuvre with cavalry, the gunners all being mounted on horses or on the carriages. These batteries in our service are armed with 9-pounder Armstrong breech-loading rifled guns. A battery of horse artillery equipped for active service consists of 253 non-commissioned officers and men, 272 horses, 6 guns with limbers, and 22 other carriages. 2. Field batteries, which are armed with 12-pounder Armstrongs, and act and manœuvre with infantry. The gunners march on foot, but can be mounted upon the carriages if required. A field battery for active service consists of 236 non-commissioned officers and men, 210 horses, 6 guns with limbers, and 22 other carriages. 3. Batteries of position, armed now with 40-pounder Armstrong guns. These batteries do not manœuvre, but follow the movements of an army, ready to take up positions as required. 4. Mountain batteries, armed with small Lancaster howitzers, which are light enough to be carried on mules, as are also their carriages.

Siege artillery, as its name implies, is used in the attack of fortified places, where it plays a most important part. The guns likely to be most used by us in future sieges are the Armstrong 40-pounders.

Garrison artillery is for the defence of fortresses and garrisons.

The 'personnel' for the service of siege or garrison guns is combined into batteries of 120 non-commissioned officers and men; which number allows three reliefs of ten men for each of three guns, and a few spare men for other purposes.

The regiment of artillery is divided into brigades, and these into batteries as above described. There is a colonel in command of each brigade, and four lieutenant-colonels. Each battery is under command of a captain, with a second captain and three lieutenants under him. The men are enlisted as gunners or drivers according to size.

A battery is the tactical unit of artillery, and three field guns to one thousand men is the average proportion in European armies. In France, as with us, a battery consists of six guns; in Russia, Austria, Prussia, Sweden and Belgium, of eight; with the Swiss, of four only.

For further information the reader is referred to the Emperor L. N. Bonaparte's learned *Études sur le Passé et l'Avenir de l'Artillerie*; and for a succinct account of the organisation and equipment of artillery, its application and theory, to Major Owen's *Lectures on Artillery*. [CANNON; GUNNERY; GUN; RIFLED CANNON; &c.]

Artillery Park. The place in a garrison, camp, or the rear of an army, where the artillery is placed. The term is also applied to the whole train of artillery belonging to an army in the field.

Artillery Train. The whole of the guns, carriages, artillery stores, &c., of an army in the field.

Artiodactyla (Gr. *ἄρτιος*, even, and *δάκτυλος*, toe). An order of hoofed *Mammalia*, with toes in even number, as two or four, and which have a subdivided or complex stomach, and a moderate-sized simple *cæcum*. To this order all those animals belong which are chiefly used for human food, and which have been domesticated from a period antedating the historical epoch. The following list exhibits the fossil and recent genera, the former being marked in italics. *Hippopotamus*, *Hexaprotodon*, *Potamohippus*, *Sus*, *Phascogærus*, *Potamochoerus*, *Dicotyles*, *Hyops*, *Calydonius*, **Palæochærus*, **Charomorus*, **Entelodon*, *Elothierium*, **Hippohys*, **Charopotamus*, *Hyotheerium*, **Bothriodon*, **Hyopotamus*, *Brachygnathus*, *Amodus*, *Archæotherium*, **Anthracotherium*, *Acotherium*, **Heterohys*, *Protochærus*, **Anoplotherium*, *Eurytherium*, *Chalicotherium*, *Tapinodon*, **Xiphodon*, **Dichobune*, **Aphelotherium*, **Hyægulius*, **Cainotherium*, *Adapis*, *Dichodon*, *Merycopotamus*, **Charotherium*, *Charomeryx*, *Camelus*, *Merycotherium*, *Agriochærus*, *Auchenia*, *Helladotherium*, *Camelopardalis*, *Sivatherium*, *Bramatherium*, *Moschus*, **Amphitragulus*, *Dremotherium*, **Dorcatherium*, **Pæbrotherium*, *Palæomeryx*, *Cervus*, *Oratherium*, *Antelope*, *Leptotherium*, *Ovis*, *Capra*, *Bubalus*, *Bison*, *Bos*. Those genera which maintained the Eocene type-dentition of forty-four teeth have an asterisk prefixed to their name.

Artocarpaceæ (Gr. *ἄρτος*, bread, *καρπός*, fruit; bread-fruit tree). A considerable division or order among urticaceous plants, which have the fruit composed of flowers combined in fleshy heads, and the stem flowing with milk, which in most cases is acrid. The Bread-fruit tree of the South Seas, and the

Upas tree (*Antiaris toxicaria*), and the famous Cowtree or Palo de Vaca (*Brosimum*), which yields a rich and wholesome milk. The Bread-fruit tree itself (*Artocarpus incisa*) is a small

ree with broad lobed leaves and large globular heads of fruit; the Jack (*Artocarpus integrifolia*) has oblong undivided leaves, and a larger, coarser, and oblong fruit. In all the species of *Artocarpaceæ* the flowers are unisexual.

Arts, Fine. This term is generally applied to those arts, in which the artist seeks chiefly to give pleasure by the immediate impression produced on the mind by his work. These arts are thus distinguished from arts which are designed to answer some practical purpose, and so have been termed useful. By some the term, fine arts, which is generally taken to include those which appeal to the eye and ear alike, has been limited to the arts of painting, sculpture, and architecture.

Aron. The name of this typical genus of *Araceæ* is in the opinion of some derived from aron, which is supposed to be the ancient Egyptian name of these or some allied plants. It consists of herbaceous perennials, mostly European, with fleshy tubers, some of them yielding starch in sufficient abundance to admit of a kind of arrowroot being prepared from them. The common 'lords and ladies' (*A. maculatum*) has been thus used in the Isle of Portland, the starch bearing the name of Portland Arrowroot. The family is nevertheless extremely acrid and poisonous, but in such cases as the foregoing the acrid matter is washed out.

Arundinaceæ (Lat. *arundo*, a reed). Any plant having the general appearance of a reed.

Arundo (Lat. *a reed*). A genus of grasses, of tall upright habit, one of which (*A. Donax*), a South European species, is grown in gardens for the ornamental effect produced by its tall leafy stems. The common Reed (*Phragmites communis*) was formerly included in the present genus under the name of *A. Phragmites*.

Aruspices or **Haruspices.** Roman soothsayers, who foretold future events from the inspection of the entrails of the victims offered at the altars of the gods. Their college was not held in the same respect as that of the augurs, and did not consist, like the latter, of men of high distinction; Cicero mentions the admission of one of their order to the senate, as an indignity to that body. Like that of the augurs, their art was brought from Etruria. The latter part of the word contains the root *spac*, to see; and Donatus derives the former part from *haruga*, a victim.

Arvales Fratres (Lat.). [AMBARTALIA.]

Arvicola (Lat. *arvum*, a field; *colere*, to inhabit). A genus of rodent, or gnawing mammals, of the numerous family of the rat and mouse (*Muridæ*), distinguished by the prismatic form and fangless structure of the molar teeth, and of which the field campagnol (*Arvicola agrestis*) and the bank campagnol (*Arvicola riparia*) are indigenous species in England. These are commonly confounded with other *Muridæ*, under the name of field mice.

Arvil Supper. A feast given at funerals in the north of England.

Aryan or **Arian Languages.** The name Aryan is applied to that great family of languages which comprises the Teutonic, Celtic, Slavonic, Hellenic, Italic, Iranian, and Indic classes of dialects. Like the Semitic, these languages belong to the inflectional stage, as admitting of phonetic corruption both in the principal root and in the terminations, and are hence called organic or amalgamating languages to distinguish them from the Turanian or agglutinative languages, which allow phonetic corruption only in the secondary elements. [AGGLUTINATE LANGUAGES.] For the origin and meaning of the term *Aryan* as applied to this family of speech, see Max Müller, *Lectures on the Science of Language*, First Series, Lect. vii. Bunsen, in his great work (*Egypt's Place in Universal History*), traces the Aryans from the original Iran in the mountains of Bactria, and assigns their first emigration to some period between B.C. 10,000 and 8000. It is almost needless to remark that for a time so long anterior to contemporary history such dates must be mere matters of speculation or conjecture. [ZEND-AVESTA.]

As (Lat.). A Roman weight nearly answering to one pound, being accurately equal to 10 oz. 18 dwt. 13½ grs. troy weight. It was divided into 12 ounces (uncie).

It was also the name of a brass coin, which originally weighed one pound, but was subsequently reduced by various degrees at different periods to half an ounce, in consequence of the gradual increase of the value of metal as compared with that of provisions and other necessities, as civilisation advanced. Its value was a little more than three farthings of English money.

Asafetida, or **Assafetida.** (Lat. *assus*, dried, and *fastidus*, fetid). A fetid gum resin obtained from the root of the *Narthex Asafetida*, whence it exudes by incision in the form of a milky juice, which, when dried by exposure to the sun, acquires a mottled appearance and pink colour. It is a native of the south of Persia, Afghanistan, the Punjab, &c., and is used in medicine as a stimulant and antispasmodic in hysteric and nervous disorders, and in spasmodic cough, asthma, and flatulent colic. Though *Narthex* is the genuine *Asafetida*, it is probable that a similar substance may be yielded by certain species of *Ferula*.

Asagrea. A plant so named after Dr. Asa Gray, an accomplished botanist of North America; it yields the Cebadilla seeds of the druggists, from which the alkaline poison veratria, occasionally employed in medicine, is prepared. *Asagrea* is a native of the cool uplands of Mexico, and has bulbous stems, linear grass-like leaves, and racemed spikes of whitish flowers. The only species is called *A. officinalis*.

Asaphus (Gr. *ἀσαφής*, obscure). A name devised to express the obscure nature of the

ASARABACCA

genus of Trilobites, fossil Crustaceans, to which it is attached; and which is characterised by tail-like appendage terminating the posterior extremity of the body, sometimes of a semi-circular form, sometimes in the shape of a short triangle, and by tuberculate eyes, which have a granular surface arising from the number of compartments (at least 400) on the surface of the cornea, containing each a separate spherical lens. Remains are found in the Wenlock limestone.

Asarabacca (*Asarum*, a kind of plant, and *bacca*, berry). A small stemless hard European herbaceous plant, called *Asarum*, with round hard chocolate-coloured three-lobed flowers, belonging to the natural order *Aristolochiaceae*. It is reputed to be a sternutatory. The French call it *cabaret*, the public-house plant, because, as it is said, it was formerly used as an emetic to relieve the stomachs of people who had been drinking too hard.

A crystallisable substance, what resembling camphor, extracted from the roots of the *Asarum Europæum*.

Asbestos, or **Asbestus** (Gr. *ἀσβεστός*, unconsumable). A fibrous variety of Actinolite or Tremolite, composed of easily separable filaments, with a silky lustre. The fibres are sometimes as fine as those of flax, and advantage has been taken of their incombustibility to weave them into a cloth, which, when soiled, regains its original purity on being heated to redness. The ancients are said to have wrapped the bodies of the dead in a cloth of this kind before burning, in order to keep their ashes separate from those of the funeral pile. Asbestos is found in Savoy, the Tyrol, and in large quantities in Corsica. It also occurs in Greenstone-dykes on either side of Llyn Padarn, and about Snowdon in North Wales; in almost all the Serpentine of the Lizard, and in the Greenstone and Serpentine of Clicker Tor, near Liskeard in Cornwall; Portsoy in Banffshire; Glenelg in Inverness-shire; the Shetlands; and in Ireland near Strabane, and at Bloomfield, county Wexford.

Asbolane (Gr. *ἀσβόλη*, soot). A mineralogical synonym for *Earthy Cobalt* [which see].

Asbolin (Gr. *ἀσβόλη*). A resinous pitchy matter obtained from wood-soot.

Ascalaphus. A Fabrician genus of insects separated from the ant-lions (*Myrmaleon*) of Linnaeus, and characterised by having nearly equal palpi; maxilla ciliate; labium horny, rounded, and entire.

Ascarides (Gr. *ἀσκάρις*, a term applied by Hippocrates to certain intestinal worms). In modern Zoology this name is restricted to a genus of round worms, or Caelaminthans, with a trilobate or trivalvular head, and a double spiculum for the intromittent organ. Two species of this genus infest the human body; one large, found in the small intestines, called *Ascaris lumbricoides*; the other of very small size, found in the rectum, called *Ascaris vermicularis*.

Ascending Weds. In Astronomy, is that

ASCENSION

point of a planet's orbit in which it crosses the ecliptic, proceeding northward. [NODA.]

Ascending Signs. The signs are said to be ascending when they are eastward from the meridian, and consequently approaching the meridian through the effect of the diurnal rotation.

Ascension (Lat. *ascensio*). In Astronomy, is either right or oblique: the RIGHT ASCENSION of a star denotes the arc of the equator intercepted between the first point of Aries and that point of the equator which comes to the meridian at the same instant with the star. The most convenient way of defining the place of a star is to refer it to the equator, and to a certain fixed point in the equator from which the degrees are begun to be reckoned. For this purpose astronomers choose the point of the equator at which the sun's path crosses it when he ascends into the northern hemisphere, which is the first point of Aries, or the vernal equinox, and reckon the degrees along the equator eastward, all round the circle. Now, to determine the place of any star, a great circle is conceived to pass through it, intersecting the equator at right angles. The distance of the star from the equator, measured on this circle, is called its declination; and the distance of the point of intersection of the equator and the circle from the vernal equinox is called the right ascension of the star. The right ascension and declination are thus the two co-ordinates by means of which the place of any star is determined. The right ascension is reckoned in time, because it is found by observing on the sidereal clock the time which elapses between the passage of the first point of Aries and that of the star over the meridian. When the first point of Aries passes the meridian the astronomical day begins; astronomers then reckon 0 hours 0 min. 0 sec. Suppose a star to come on the meridian 5 hours 35 min. 26 sec. after this; then 5 hours 35 min. 26 sec. is the star's right ascension in time, and is equivalent to an arc of the equator of $83^{\circ} 51' 30''$, because an hour in time corresponds to 15° in space, and a minute or second in time to 15 minutes or seconds in space. If the clock, therefore, is regulated to keep time with the heavens, the time indicated by the clock at which any star passes the meridian is the right ascension of the star in time. The OBLIQUE ASCENSION of a star is the arc of the equator intercepted between the vernal equinox and that point of the equator which comes to the horizon at the same time with the star. This varies with the latitude of the place of observation. At the equator it coincides with the right ascension. This term is now seldom used in astronomy.

Ascension. In Theology, the reception of our Saviour into glory, after His last appearance on earth: celebrated in the Christian Church on the last Thursday but one before Whitsunday. Rogation week, that in which the Ascension is celebrated, is so termed from the rogations (petitions or litanies) which were

used in the perambulation of the bounds of the parish, which, according to ancient usage, took place in this week.

Ascensional Difference. In Astronomy, is the difference between the oblique and the right ascension. This term is chiefly used in respect of the sun, because when the arc which it denotes is turned into time it shows the time before or after six o'clock of sunrise. The sine of the ascensional difference is equal to the tangent of the latitude multiplied into the tangent of the star's declination; hence, when the declination of a star is north, its oblique ascension is found by subtracting the ascensional difference from the right ascension, and when the declination is south, by adding the ascensional difference to the right ascension.

On account of the greater precision with which observations are made with fixed meridional instruments, all astronomical elements are now computed from observations of right ascension and declination; but in ancient times the positions of the celestial bodies were chiefly referred to the horizon, and hence the *oblique ascensions* and *ascensional differences* entered constantly into the solutions of astronomical problems.

Ascent (Lat. *ascensus*). In Mechanics, the motion of a body from the earth's centre. [ACCELERATION and RETARDATION.] In Geometry, the *lines of steepest ascent* on any surface cut the *lines of level* at right angles. [SLOPE; LEVEL; DESCENT.]

Ascetics (Gr. *ἀσκητός*, from *ἀσκέω*, I exercise). Persons who, in the early ages of Christianity, devoted themselves to a solitary and contemplative life, following the system of the Essenes and Therapeutæ among the Jews, and practising great austerities, with a view to mortify the flesh and withdraw the mind from worldly objects. They haunted the deserts of Egypt and Syria, and appear to have suggested the first idea of Christian monachism.

Ascians or Asci (Gr. *ἀσκιος*, from *ἀσκη*, priv., and *σκιά*, shadow). A term found in the older works on geography, and used to denote those inhabitants of the globe who at certain times of the year have no shadow. This can only happen with respect to the inhabitants of the torrid zone, who, twice a year, have the sun in the zenith.

Ascidian, Ascidia (Gr. *ἀσκιδιον*, dim. of *ἀσκάς*, a bottle or pouch). A genus of heterobranchiate acephalous Mollusks, or Tunicaries, characterised by a body having the form and commonly the consistence of a tough leather pouch, attached to some foreign substance, and with two openings, one branchial, and the other anal, from which streams of water are forcibly ejected when the animal is touched or irritated.

Ascidium (Gr. *ἀσκιδιον*). A hollow pitcher-shaped body found upon the stems of certain plants, as *Nepenthes*, *Sarracenia*, &c. It usually contains water, and is sometimes clothed with reflexed hairs, which prevent the escape of insects which fall into it; its use is unknown.

In *Dischidia*, it is in reality a leaf rolled up till its edges touch, when they grow together; in *Marcgravia*, it is a bract in the same state.

Ascites (Gr. from *ἀσκάς*, a leather bag or bottle). Dropsy of the abdomen.

Asclepiadaceæ (Asclepias, one of the genera). Monopetalous Exogenous plants, with bifollicular fruit, the stamens adhering to the stigma, which is large and pentagonal, and having an acrid milk in their stems. They are exceedingly different in appearance, some being trees with showy flowers, others obscure twiners with very inconspicuous herbaceous corollas, others herbaceous plants with clusters of gaily coloured flowers, and others leafless decumbent shrubs with angular stems and brown flowers having a putrescent odour. The latter are *Stapelias*. *Hoya*, with its delicate waxen flowers running with honey, is a genus of the order; and another is the curious climbing water carrier called *Dischidia*, which mounts to the tops of lofty trees with its fleshy bags filled with a constant supply of fluid. Some of the species are valuable for the toughness of the fibre extracted from their stems. The milky secretion of these plants contains caoutchouc; it is of an emetic nature, and in some cases poisonous. *Asclepias tuberosa*, the Butterfly weed of North America, is the handsomest of the hardy species.

Asclepiadine. A bitter non-azotised emetic met with in the root of *Asclepias Vincetoxicum*.

Asclepien. A tasteless neutral body contained in the juice of *Asclepias syriaca*.

Ascus, pl. **Asci** (Gr. *ἀσκάς*). Little membranous bags or bladders, in which the seed-like reproductive particles or spores of Lichens, Fungi, &c. are enclosed.

Asexual Plants. The same as Cryptogams, though modern discoveries show the application of such a name to be erroneous, sexual organs having been discovered in all the great divisions of Cryptogamous plants.

Ash (A.-Sax. *æsc*). The *Fraxinus* of botanists, consists of several species of hardy trees, usually valuable for their timber. The tough ash wood of carpenters is yielded by *F. excelsior*, and the sweet substance called manna by *F. Ornus*. They mostly bear flowers without petals; but the latter species having those organs developed, is called, in distinction, the Flowering Ash.

Ashlar. The name given to the dressed stones used for facing work, when it is worked in regular beds and joints.

Ashlaring. The stone used as ashlar is called ashlaring, when in thin slabs, and made to serve merely as a case to the regular body of the wall. In this case the ashlar stones require to be well bonded to the subjacent structure, and to be tied in at distances by bond courses.

Ash-Wednesday. The first day in Lent, in the Latin Church dies cinerum, the day of ashes, so called, because in the primitive Church

ASIA

it was the custom on that day for penitents to appear in church clothed in sackcloth, upon which occasion ashes were sprinkled upon them.

A great tract of land, ranging over nearly 180 degrees of longitude, chiefly in the north temperate zone of the eastern hemisphere. It is crossed almost from east to west by a broken chain of high ground which in one part rises into the loftiest elevations of the globe, and which in various other parts rises into important mountain chains. Numerous rivers proceed from this mountain chain to the ocean. Of this great tract, which is connected with Africa only by a narrow and insignificant isthmus, the part east of Africa is called the Asiatic, and the part to the west, the European continent. There is no natural division between them, except the low chain of the Urals.

Asia presents many peculiarities of physical geography. Besides possessing the loftiest land on the globe, it has in many parts a singularly broken outline of coast, and a remarkable fringe of islands. It has few considerable lakes, but many vast plains crossed by gigantic rivers forming large river systems. Its climates are as variable as any that may be met with on the earth. It penetrates far into the arctic circle, and enters the tropics by three important peninsulas. The islands parallel to its coast and projecting from its peninsulas are not less interesting than the main land itself. We may consider separately its mountains, plains, and river systems. The adjacent islands will be mentioned under their respective names.

Mountain chains.—The middle portion of Central Asia presents four systems of mountains ranging from west to east and parallel to the greatest dimension of the whole tract of land. There are many subordinate ranges, generally parallel to the coast lines.

These four systems connect with and form parts of one principal mountain axis attaining its greatest elevation in the Himalayan chain, at a point nearly midway between the valleys of the Indus and the Brahmapootra. At this point rise the peaks of Dhawalagiri to the height of at least 28,000 ft. above the sea. To the north are ridges separated by very lofty table land, and terminating in the Altai mountains. To the east extend the mountains of China in the south, and those of Manchou Tartary in the north, while westwards the Himalayan range is connected with the Taurus and the Caucasus by the table lands and mountains of Persia, and so passes into Europe to join the Alps. Besides the main chain there is an important east and west chain in Northern India (the Vindhya chain) and numerous series of mountains running southwards towards the volcanic islands of the Indian Archipelago. The Arabian mountains, passing away to the south-west, furnish the connecting link with the extremely lofty and recently determined snow mountains of Africa south of Abyssinia.

Not only are the separate peaks of the Himalaya of extraordinary elevation, but the

mean height of the mass far exceeds that of any other mountain chain. It is variously estimated at from 12,000 to 20,000 ft., but not less than forty peaks of the chain are more lofty than Chimborazo, and a large number of them certainly exceed 25,000 ft. Throughout this district of the higher mountains the valleys are deep gorges, and the descent to the plains on the south side is extremely and unusually rapid, there being nowhere any extent of level ground.

The northern side of the Himalayas is little known and very difficult of access. The plains, however, on that side are very lofty, and the final termination in the Altai chain does not rise very high above the foot of the plains of Central Asia.

The snow line on the Himalayas is very high, and much higher generally on the north than on the south side. The passes across are few and lofty: several are far above the summit of Mont Blanc. One of them is estimated at 20,000 ft., and all are dangerous and difficult, owing to the extremely narrow width of the valleys and the suddenness with which the rise takes place from the southern side.

Many of the mountains of the northern part of the great range are volcanic; but this is not the case with any of the loftier peaks, which are either of granite, gneiss, or quartzite. The western extensions of the main chain are lost in the table lands around the great Aralo-Caspian district, and connect themselves with the Ural chain in the north as well as with the Caucasus and Taurus in the west. The table land of Arabia and its recent volcanic aspect may hereafter afford a clue to the more modern changes that have taken place in this great district of elevated land.

Plains.—Of the land north of the Himalayan mountains, as well as of that to the south and west, the greater portion is true table land, though much of it is traversed by gigantic rivers. In the west the plateau of Iran or Persia, and that of Arabia, are both remarkable for their general barrenness, in a part of the world where rain alone is almost sufficient to insure abundant vegetation, and this character of barrenness seems to extend widely towards the east. This western plateau is estimated to occupy 1,700,000 square miles, and to have a general elevation of nearly 4,000 ft. The plains of Armenia and the great salt desert of Persia are, however, almost double that elevation.

The eastern plains of Thibet are separated from the western plains of Persia. A vast tract of very unequal elevation, but some of it of enormous height, extends in a series of steps ascending towards the Arctic Ocean. Upwards of seven and a half millions of square miles of land are thus included. This tract is for the most part little known, but the northern part is traversed by the gigantic rivers Obi, Yenesei and many others. Parts of this plain are 17,000 feet above the sea. The plains of India occupy the southern part of the penin-

sula, and are terminated by the Ghâts or coast ranges of hill.

River systems.—The river systems of Asia are on the grandest scale, and divide themselves into three series; those, namely, which drain into the Arctic Sea, those which enter the Indian Ocean, and those which terminate in the Pacific. There is besides a great internal basin connected with the table-land of Central Asia, and more especially with the ARALO-CASPIAN region [which see].

Of the Asiatic rivers which empty themselves into the Arctic Sea three are of gigantic proportions, each having a direct course of about 1,500 miles, nearly doubled if the principal windings are included, and each draining an area of nearly a million square miles. There are more than six other large rivers, but of inferior importance. All these traverse vast dreary plains, the northern declivities of the table land of Asia, but the sources of their principal feeders are to be found at elevations very inconsiderable. The streams therefore have slow courses, easily interrupted, and forming marshes of variable and hardly measurable extent. These characterise a great part of Siberia. Two of the principal streams, the Lena and the Yenesei, terminate in deltas which are frozen for nine months of the year. The Yenesei in the upper part of its course expands to form the great lake of Baikal. The Obi, the most westerly and the largest stream, is one of those that has the slowest course.

The rivers emptying into the Pacific are also of the first class. The Hoang-ho and Yang-tse-Kiang, each draining more than half a million of square miles, and each having a direct course of more than twelve hundred miles without including windings, rise together in Central Asia, and bring down vast quantities of mud, which they deposit near their mouths in the Yellow Sea. The Amour, with a larger drainage area, and a course only a little shorter, runs chiefly through Russian territory into the Sea of Okhotsk.

In the extent of their river basins and the length of their respective courses, the Ganges and Brahampootra, the Irawady, the Indus, and the other streams entering the Indian Ocean, are inferior to the great rivers of Northern Asia, although from their position, and political and historical interest, they are much more important. The Ganges and Brahampootra form a remarkable double river system, the sources of the two streams being at the two extremities of the Himalayan chain, and the waters converging in a magnificent delta at the head of the Bay of Bengal. The volume of water discharged is very large, and the thick jungle vegetation of the delta is a striking feature. The Indus and other rivers also rise in the Himalayan chain. The Euphrates and Tigris originate in the table land of Armenia. They also combine near the coast.

Several rivers not communicating with the ocean traverse parts of Central Asia: no less than six river systems here occur which have

no drainage beyond the table land. The evaporation from the lakes is equal to the quantity of water entering them by the different streams. One of these rivers, entering the Sea of Aral, is not inferior to the Danube in length of course and drainage area. The Volga, entering the Caspian Sea, is a still more important stream.

Lakes.—The lakes of Asia, except the Caspian Sea, the Sea of Aral, and Lake Baikal, are of trifling importance and are little known. These three, especially the first and third, are of large dimensions and considerable interest, but they are much smaller than the lakes of North America. [ARALO-CASPIAN.] Unlike the principal lakes of the New World, they receive rivers and have no outlet. In this respect they approximate in some measure to the condition of the interior of Africa and Australia, but the physical features of these central plains are distinct. There are some salt lakes in Central Asia and some extensive volcanic districts.

Of the Asiatic Islands those of the INDIAN ARCHIPELAGO are the principal, and are separately described. The Japanese islands are very remarkable and extensive, but are even now little known. The Andaman group and other islands of the Indian Ocean are partly volcanic and partly coralline. Ceylon belongs to the Indian peninsula.

Asiarch (Gr. ἀσιάρχης). A title given to the highest religious official in that district of Asia Minor, round Ephesus, which was known especially as the Roman province of Asia. (See Acts of the Apostles, xix. 10, 22, 26, 31.) The Asiarch generally resided at Ephesus. In the same way Bythinarchs, Galatarchs, &c., regulated religious rites and games in the Roman provinces of Bithynia, Galatia, &c.

Asilus (Lat.). A Linnaean genus of Dipterous insects, in which the mouth is furnished with a horny, projecting, straight, two-valved sucker, and gibbous at the base: antennæ filiform, approximate, of two articulations; body, oblong and conical in shape. The insects of this genus prey on other insects, especially those of the Dipterous and Lepidopterous orders.

Asmodeus. The name of an evil spirit, representing the Aêshma-daêva of the Zend-avesta. The occurrence of this name in the Book of Tobit, iii. 8, 17, shows the influence of Iranian demonology on the Hebrew mind at the time when that book was written. (Bréal, *Hercule et Cacus*, 135.)

Asp (Gr. ἄσπις, an asp). A species of poisonous serpent frequently mentioned by ancient authors, some of whom describe its bite as being inevitably mortal, and say that the bitten die within three hours, and without pain, being thrown into a deep sleep; whence it was selected by Cleopatra as the instrument with which at once to terminate her existence, and bereave her conqueror of the chief feature of his triumph. There is always much difficulty in identifying the precise species mentioned in the classical writings of antiquity, from the

ASPARAGIN

vague manner in which they are there spoken of. Some naturalists are of opinion that the species of hooded viper, called by the modern Arabs 'El Haje' [*Vipera (Naja) Haje*, Cuvier], is the 'Aspis' of the ancients; and as it possesses the power of distending the skin of the neck, like the Indian Cobra di Capello, it agrees with one of the characters assigned by Pliny to the Aspis—'Colla aspidum intumescere,' lib. viii. The size, however, of the Haje, which varies from three to five feet, is greater than that which is usually attributed to Cleopatra's asp.

Asparagin. A white crystallisable substance obtained from the expressed juice of asparagus. It has been proposed as a diuretic in medicine.

Asparagineæ (Gr. *ἀσπαραγος*). A genus of spiny Liliaceous plants, many of which are shrubs, and climb upon other plants. They all have minute scale-like leaves, small white or greenish flowers, and berried fruit; very often they produce short leafless branches, in room of leaves. *Asparagus officinalis*, one of the few species which neither climb nor bear spines, is found wild occasionally on the seashore near Weymouth. The succulent shoots which it throws up from its underground eyes are the asparagus of the market gardeners. It is not a little singular that, although this plant has been an object of careful cultivation for so many years, it should never yet have produced a well-marked permanent variety; the sorts, as they are called in the shops, are produced by casual differences of soil or cultivation, and are not distinct varieties.

Asparaginous Plants. In a strict sense this term ought to be applied only to such plants as belong to *Asparagineæ*; but in horticulture it is used to signify all those culinary vegetables the points of the tender shoots of which are eaten when they just emerge from the soil, in the same manner as those of asparagus: such, for example, as the points of the common hop, of the sea-kale, &c.

Asparamide. Another name for asparagin. [ASPARAGIN.]

Aspartic Acid. When asparagin is boiled with magnesia it is resolved into ammonia and a peculiar acid called as above.

Aspasolite. A variety of Iolite occurring in six-sided and twelve-sided prisms, of a greenish-grey to a whitish colour and with a feeble lustre, at Krageroe in Norway.

Aspect. [ASTROLOGY.]

Aspergilliform (in Ecclesiastical Latin, aspergillus, the brush with which holy water is scattered about in Roman Catholic places of worship). Anything shaped like an aspergillus; it is chiefly used in speaking of the stigmata of graces.

Aspergillum. A genus of tubular Bivalves, characterised by the soldering of both valves to the inner surface of the calcareous sheath; which is dilated or club-shaped at the lower end, and perforated there by many small

ASSADULCIS

holes, whence it has obtained the trivial name of the 'Watering-pot Shell.' In the system of Woodward, this rare and remarkable genus ranks among the Family *Gastrochenida* of the Class *Acephala*.

Asperifoliæ (Lat. *asper*, rough, *folium*, a leaf). The name given by Linnæus to the plants now called Boraginaceous.

Aspermous (Gr. *ἀσπερμος*, from *ἀ*, without, *σπέρμα*, seed). In Botany, destitute of seed.

Aspertannic Acid. An organic acid said to exist in the *Asperula odorata* or Sweet-scented Woodruff.

Asphalt, or Asphaltum (Gr. *ἄσφαλτος*). A compact kind of Bitumen. It is black, very fusible and inflammable, burning with a smoky flame. It is found in great abundance on the surface and shores of the Dead Sea (which has been called in consequence the Asphaltic Lake); in the islands of Barbadoes and Trinidad; in a lake in Texas about a quarter of a mile in circumference, and in various other localities. The ancients employed it in some of their cements, and it was also used by the Egyptians in the process of embalming, either alone or in combination with other substances. At present its principal use is for pavements, and as a constituent of varnishes.

Asphodelææ (Asphodelus, the principal genus). A subdivision of the natural order *Liliacææ*, comprehending the Onion, the Squill, the *Ornithogalum*, *Anthericum*, *Asparagus*, and similar genera. They differ little from true *Liliacææ*, except in the size of their flowers, which are usually smaller. [LILIACÆÆ.]

Asphyxia (Gr. *ἀσφυξία*, from *ἀ* priv., and *φύξις*, pulsation). A fainting fit: a state in which the pulse cannot be felt, and in which the powers of mind and body are suspended.

Aspidorhynchus (Gr. *ἀσπίς*, a shield, *ῥύγχος*, a beak). The name of a fossil extinct genus of Sauroid fishes characterised by the length and bony covering of the upper jaw.

Asplenium (Gr. *ἀσπληνον*). The type of one of the principal minor groups into which ferns are divided by recent pteridologists, the old genus *Asplenium* being the equivalent of the modern *Aspleninae*. They are known by their indusiate sori, in longer or shorter lines, and seated laterally on the veins to which they are attached. There are, according to some authorities, about 300 species in the modern restricted genus, which excludes all those with retted venation, as well as those with double sori, either set back to back on the same vein as in *Diplazium*, or set face to face on contiguous veins as in *Scolopendrium*. The name *Asplenium*, whence comes Spleenwort, was given from some supposed virtues in affections of the spleen, possessed by species once referred to his genus, but which are now removed. Indeed the Miltwaste, or Spleenwort, which seems to have had most repute, was the plant now known as *Ceterach officinarum*.

Assadulcis, or Asadulcis (Lat. *assus*, wild, and *dulcis*, sweet). A gum resin, supposed to be the produce of *Thapsia gurganica*,

ASSAI

and held in high repute among the ancients. The term has also been applied to benzoin.

Assai (Ital. *enough*). In Music, an adverb of quantity prefixed to such words as *allegro*, *adagio*, &c., signifying that the motion of the bars or measures should be kept at a mean rate of quickness or slowness, quick or slow enough, but not too much so.

Assamar. One of the constituents of burnt sugar. Toasted bread is said to owe its flavour to this substance.

Assassins. Those who attack and kill by treachery and violence persons unprepared for defence. The word is derived from a military and religious order, formed in Persia by Hassan Ben Sabah, about the middle of the eleventh century, and called Assassins from their immoderate use of Hæschisch (henbane), which produced an excitement amounting to fury. So the Assassins, instead of a secret murderer, means, in fact, 'an habitual drunkard.' Hammer, in his History of the Assassins, has opened some new and striking views of the origin, proceedings, and doctrines of this sect. Their principal seat was in the mountains; and they were subject to the control of a prince, or, according to Hammer, a grand master, who possessed such an ascendancy over his fanatical subjects that they paid the most implicit deference to his commands, and courted danger, and even certain death, in the execution of his orders. Nor did they stoop to humble prey; for the more lofty the object of their hatred, the more sure and deadly was their aim. In the time of the crusades they mustered to the number of 50,000, and presented a formidable obstacle to the arms of the Christians. Among the victims of their swords, at this period, may be mentioned Conrad, Marquis of Montferrat, who was murdered in the market-place of Tyre, in the year 1192. Several historians have charged upon Richard I. the instigation to this crime; but his guilt is very doubtful. (Gibbon, *Roman Empire*, ch. lix.) Long after this period the Assassins continued to levy contributions; but, after an obstinate resistance, they were at length effectually crushed by the Sultan Bibars. Scattered abroad, however, hated and despised, the order of the Assassins, like that of the Jesuits, survived long after its nominal suppression; and remnants of the Assassins still exist both in Persia and Syria, but merely as one of the many sects and heresies of Islamism, and utter strangers to the murderous tactics of their predecessors.

The numerous battles and enterprises of the Assassins, their valorous defence against the armies of the crusaders and the Sultan, and the adventurous character of their whole history, opened to Syrian writers a fertile source of romance, of which, according to Hammer, they have freely and skillfully availed themselves.

Assault (Fr., from Lat. *assilio*, *I leap upon*). In Fencing, a mock engagement with foils, in imitation of a real single combat.

ASSAULT. In Law, includes a great variety

ASSEMBLY

of violent acts committed against the person of another, from a mere blow, or even attempt to strike, to the most serious injuries. 'Battery,' or actual beating, though generally charged as an indictment together with assault, is held to comprehend it. A 'common' assault is distinguished from an assault 'with intent' to commit murder, or any minor offence. Common assaults are punishable by summary conviction before two justices under 24 & 26 Vict. c. 100.

ASSAULT. A term generally applied to an effort by an attacking party to carry by open force a strong position, fortified post, camp, or the breach made in a fortress.

Assay (Fr. *essayer*, *to try*). This term is sometimes employed as synonymous with analysis, but more generally restricted to the determination of the composition and consequent value of alloys of gold and silver. From the quantity of coin, plate, and trinkets constantly fabricated, the art of assaying is of much importance, and requires considerable practical skill in its performance. At the Mint there were originally two assay masters, the master's assayer and the king's assayer: the business of the former was to receive the gold and silver ingots brought for coinage, to cut one or more pieces from each ingot, and to make written reports of each assay. The king's assayer examined the melted bars previous to their passing into the moneyers' hands for coinage, and was responsible for their standard purity: and the money coined was not allowed to go out of the mint until pixed; that is, until it had been ascertained, by the assay of one piece taken out of each journeyweight of coin, that it was of standard purity: the king's assayer therefore was a check officer upon the melter and upon the coiner, and was responsible for the standard purity of all gold and silver coin issued from the Mint. About twelve grains of gold, and twenty grains of silver, are usually employed for the assay. In the present arrangements at the Mint, the work of the king's assayer has been transferred to out-of-doors hands, but the duties of the master's assayer are conducted, as heretofore, within the Mint.

Assembly (Fr. *assemblée*). In French history, the four great legislative bodies which succeeded each other during the period of the first Revolution, are usually termed, 1. The *National or Constituent Assembly*; commenced 17th of June, 1789, by the resolution of the deputies of the communes in the States-General, constituting themselves a national assembly, to which the deputies of the nobles and clergy afterwards adhered; termed Constituent Assembly from having framed a constitution: dissolved on the acceptance of the constitution by the King, 30th of September, 1791. 2. The *Legislative Assembly*: it commenced its sittings October 1, 1791: suspended the royal authority by its decree of the 10th of August, 1792; and was dissolved September 21, 1792. 3. The *Convention* [*CONVENTION*]: it commenced its

ASSESSMENT

sittings September 21, 1792, with a proclamation of the Republic: was dissolved 4 Brumaire, 4th year of the Republic (Oct. 26, 1795). 4. Two-thirds of this assembly were then included in the new body of the 'Corps Législatif' which commenced its sittings Oct. 27, 1795, forming two councils, 1. of 500 (*des Cinq-cents*); 2. of the Ancients (*des Anciens*), 250 in number. The latter body named the Directory. This assembly subsisted until the dissolution of the Directory by Bonaparte, 19 Brum. 8th year of the Republic (Nov. 10, 1799). [DIRECTORY.] The term *Assemblée Nationale* was revived for the legislative body under the second Republic, May, 1848.

ASSEMBLY, the General, of the Kirk of Scotland, is the highest ecclesiastical court of that establishment. It meets annually in May, and sits for ten successive days, with power to appoint a commission to take cognisance of any cases undecided within that period; the commission being, in fact, a continuation of the assembly, with one additional minister named by the moderator. The assembly consists of representatives from the presbyteries, royal burghs, and universities of Scotland, and from the churches in the East Indies connected with the Kirk: in all about 380 members. The meeting of the assembly is attended by a nobleman as representative of the king, with the title of Lord High Commissioner: who, however, takes no part in the proceedings. The moderator, or president, is chosen by the assembly yearly. The General Assembly is a court of appeal from the Presbytery and Synod.

Assessment. In Law, any tax imposed on persons or property. [DAMAGES.]

Assessor. In Law, a person possessed of knowledge of the law, appointed to advise and direct the decision of the judge. In various inferior courts assessors are appointed by statute. Assessors were employed, previously to the Reform Act, to assist the returning officer in deciding on the cases submitted to his cognizance at the period of an election. By the Municipal Corporation Reform Act (5 & 6 W. IV. c. 76, s. 37) the burgesses of every borough are directed to elect two assessors, for the purpose of assisting the mayor in his duty of revising the burgess lists and presiding at the elections. And, by sec. 43, the burgesses of each ward are to elect two assessors for the purpose of assisting the alderman at the ward elections.

Assets (Fr. *assez*, enough). In Law, the fund out of which a deceased person's debts are to be paid. All the property of a deceased person is now liable to the payment of his debts, the unjustifiable exemption of landed property having been finally removed in 1833 by Sir J. Romilly's Act (stat. 3 & 4 Wm. IV. c. 104).

Assiento Treaties (Span. *agreement*). In History, the contracts entered into by Spain with several European nations (first Portugal, then France, and after the Peace of Utrecht in 1713, England), to supply her South American

ASSUMPSIT

colonies with negro slaves from Africa, were so termed.

Assignats. Paper-money issued by the French Government at various periods during the Revolution, based on the security of the unsold lands of the clergy, emigrated nobles, &c., which had become forfeit to the nation.

Assignment. In Law, is the total alienation of a chattel interest: which, by the third section of the Statute of Frauds, must be, if of a term of years in land, by writing and signature. *Assignee* is the party to whom an assignment is made.

Assimilation (Lat. *assimilatio*). The act by which organised bodies incorporate foreign molecules and convert them into their own proper substance.

Assize (Nor. Fr. *assise*). 1. In a sense now obsolete, an ordinance or constitution of the sovereign: thus, the code of feudal law framed for the kingdom of Jerusalem under the Crusaders is termed the *Assises de Jérusalem*. 2. The ordinances regulating the price of bread and other necessities were also called *Assizes*. 3. The peculiar jury by which a writ of right was tried, was termed the *Grand Assize*. 4. In the only sense in which the word is now an existing law term, the *assize* signifies the periodical session held by the judges of the superior courts in the counties of England, for the purpose of trying issues *a nisi prius* and delivering the gaols. [COURTS SUPERIOR.]

ASSIZE. In Scotch Law, a term synonymous with the English jury—the assize consisting of fifteen men.

Association. In Psychology, a name given to that property of our minds, by which any object or state of consciousness (whether image, thought, or emotion) has a tendency to recall other states or objects of consciousness with which it has been previously in some way connected. The conditions under which this tendency exists were first stated by Aristotle, in his *Treatise on Memory and Recollection*. According to him they are threefold, consisting of Resemblance, Contrast, and Contiguity. If by the last word we understand connection in space and time, and that of cause and effect, this division is the same with that given by Hume, and adopted by modern philosophers. The principle of association has been applied by Hartley, Sir J. Mackintosh, Bain, and other writers on ethics, to explain the origin of our more complex emotions, and in particular of our moral sentiments.

Assonance (Lat. *assono*). In Rhetoric and Poetical Composition, a jingle or imperfect rhyme, formed by separate words, or members of a sentence.

Assumpsit (Lat.). In Law, is an action of an anomalous character, having the form of tort and the substance of contract. It is, properly, a claim of damages sustained through the breach of a simple contract (i.e. a promise not under seal), and alleges that the defendant *assumpsit*, i.e. promised, or undertook to per-

ASSUMPTION

form the acts specified. It has become the most ordinary remedy, not only where unliquidated damages, but also where debts are sued for; the law implying a promise to pay or do whatever the defendant is legally liable to pay or do.

Assumption (Lat. *assumptio*). A festival of the Romish Church, kept on August 15, in celebration of the alleged miraculous ascent of the Virgin into heaven.

Assumptive Arms. In Heraldry, such as may be assumed with the approbation of the sovereign, or by a grant from the proper officers of arms: also, in another sense, armorial bearings improperly assumed.

Assurance (from Low Lat. *assecuro*, *I guarantee*). A contract for the payment of a certain sum on the occurrence of a certain event. The term assurance is generally confined to those contracts under which a certain sum is to be paid on the death of an individual or individuals now living; while insurance is applied to those which provide for the payment of a sum on the occurrence of events not depending on the duration of human life, and which may never happen, such as the loss of ships at sea, the destruction of houses by fire, &c.

Assurances on Lives are contracts which stipulate for the payment of a certain sum of money on the death of one or more individuals, in consideration of an immediate payment, or, more frequently, of an annuity or annual contribution, to be continued during the existence of the lives assured. Contracts of this kind are of immense importance to society. Every man whose income depends on his own life or exertions, and on whom others are dependent for support, must be sensible of the advantages of arrangements by means of which, at a small sacrifice of immediate comfort, he is enabled effectually to provide against the casualties of life. They are of a totally different nature from gambling. Though nothing can be more uncertain than the continuance of an individual life, yet nothing is more invariable than the duration of life in the mass; consequently, the exact value of life assurances can be calculated without any uncertainty whatever, and a man, by effecting an assurance, secures to his representatives, against the risk of accident, the advantages they would have from his enjoying his exact proportion of the average duration of life. Such transactions provide against destitution, and tend directly to the accumulation of capital; they will, therefore, be encouraged and protected in all well-governed communities.

Method of computing the Value of Assurances.—The value of assurances on lives is computed in nearly the same manner as those of annuities, the principles being the same in both cases. A table of mortality must first be selected, from which we deduce the probabilities of living over the different years of life. Having obtained these, and assumed a rate of interest, we proceed as follows: let the

ASSURANCE

probabilities that an individual of a given age will live over

1, 2, 3, 4, 5, &c. years
be p_1, p_2, p_3, p_4, p_5 , &c. respectively;

also, let r be the rate of interest, and $v = \frac{1}{1+r}$ and suppose that the sum assured is to be paid at the end of the year in which the life falls. Now, the value of $1l.$ to be received at the end of the first year is v , but it will not be received if the life continues to the end of the year; and, as the probability that the individual will live over the year is p_1 , the probability that he will not live over it is $1-p_1$, therefore the value of $1l.$ to be received at the end of the year, subject to the contingency of the life failing in the first year, is $(1-p_1)v$. The probability that the life will continue to the end of the second year is p_2 , and that it will continue one year only, p_1 , therefore p_1-p_2 is the chance it will drop in the second year; and the value of $1l.$ to be received at the end of the second year is v^2 , therefore the present value of $1l.$ to be received if the life fails in the second year is $(p_1-p_2)v^2$. In like manner, the probability that the life will fail in the third year is p_2-p_3 ; and the value of $1l.$ to be received at the end of three years is v^3 , therefore the present value of $1l.$ to be received at the end of three years, if the given life fails in the third year, is $(p_2-p_3)v^3$. The same process is continued from year to year, till the probability of living over a year becomes nothing. Now, the whole value of the assurance is manifestly equal to the sum of all its partial values for the different years; therefore, denoting the value by I , we get
$$I = (1-p_1)v + (p_1-p_2)v^2 + (p_2-p_3)v^3 + \&c.$$
 or, separating this into two series,

$$I = v(1 + p_1v + p_2v^2 + p_3v^3 + \&c.) - (p_1v + p_2v^2 + p_3v^3 + \&c.)$$

But it is shown in the article ANNUITY that the series $p_1v + p_2v^2 + p_3v^3 + \&c.$ denotes the value of an annuity of $1l.$ on a life, the probabilities of the continuance of which are represented as above; therefore, calling this annuity A , we have $I = v(1 + A) - A$.

Since $v = \frac{1}{1+r}$, this formula becomes by substitution $I = \frac{1}{1+r}(1 - rA)$.

The sum now found is what ought to be paid down, in order to receive $1l.$ on the failure of the given life; but by far the most usual practice is to pay for the assurance by means of an annual premium, the first payment being immediate, and the others at the end of each successive year. Let π be the annual premium; then the value of all the premiums after the first is obviously the same thing as the value of an annuity of the same amount, and is, consequently, equal to πA . Hence, the value of all the premiums is $\pi + \pi A$, or $\pi(1 + A)$, which is necessarily equivalent to the assurance. We have therefore the equation $\pi(1 + A) = v(1 + A) - A$, whence $\pi = v - \frac{A}{1 + A}$.

ASSURANCE

This formula is very easily computed when we are in possession of a table of annuities, and it shows at once the annual sum which an individual of any age ought to pay, in order to secure to his representatives $1l$, (and, consequently, any other sum) at his death.

Temporary Assurances.—The values of temporary assurances, or engagements to pay a certain sum in case a given individual dies within a given number of years, are easily found from those on the whole of life. For example, let it be required to find what sum ought to be paid for $1l$, to be received if an individual now aged 40 shall die within seven years. Let I be the value of $1l$ to be paid on the death of a person aged 40, and I_7 the present value of the same sum, to be paid on the death of a person aged 47. Seven years after this the value of an assurance of $1l$ on the death of the person now aged 40 will be I_7 ; but the present value of $1l$, to be received certainly at the end of seven years is v^7 , and the probability that the life will continue seven years is p_7 ; therefore the present value of I_7 on the contingency that the life will not fail within seven years, is $p_7 v^7 I_7$; subtracting this from I , the value of $1l$, to be received certainly at his death, there remains $I - p_7 v^7 I_7$, to denote the value of the temporary assurance. This may be expressed by the following rule. Multiply the assurance on a life seven years older than the given life by the present value of $1l$, payable seven years hence, and also by the probability that the given life will survive seven years; subtract the product from the assurance on the given life, and the remainder is the value of a temporary assurance for seven years in a single payment.

In order to find the equivalent annual payment, it must be recollected that the first payment is made immediately, and that seven payments are to be made in all; consequently, all the payments after the first are equal to a temporary annuity of the same amount for six years, or one year less than the given term; consequently, if π represent the annual premium, and A' a temporary annuity of $1l$ for one year less than the given term, the value of all the premiums to be received is $\pi + \pi A'$ or $\pi(1 + A')$, which by hypothesis is equal to the assurance; consequently, to find the annual premium, we have to divide the value of the temporary assurance in a single payment by $1 + A'$.

In the same manner, the value of an assurance on any number of joint lives is found: it is only necessary to substitute for A in the above formulas, the value of an annuity on the joint lives. Thus, let M be the value of an annuity, to continue while A and B both live, then $v(1 + M) - M$ is the value of an assurance to be paid at the end of the year in which the first of the two lives shall fail, and the

equivalent annual payment is $v - \frac{M}{1 + M}$.

A very important class of assurances comprehends those in which the contract is to pay

ASTERIODS

a sum on the death of one party, provided that another party shall be then alive. The computation of the values of such contracts is somewhat more intricate, and cannot be explained without entering into details respecting the manner of combining the probabilities of life, which our limits will not permit.

For assurances on ships and goods, see **INSURANCE**.

Astacus (Lat. *a lobster*). The name of a Fabrician genus of insects, and now the type of a family (*Astacidae*) of Decapod, Macrourous, or long-tailed Crustaceans; including the lobsters (*Astacus* Leach), the crawfish (*Potamobius* Leach), and the cray-fish or spiny lobsters (*Palinurus* Leach). The distinguishing character is derived from the antennæ, the two pairs of which are inserted in the same horizontal line; the mesial ones having moderate or long footstalks, terminated by two filaments; the outer ones naked, or furnished with a scale which never entirely conceals the base.

Astarte. In Mythology, a Phœnician goddess called in the Scripture Ashtaroth. This goddess is probably identical with the Greek Aphrodite, whose connection with Adonis has a distinct reference to the mythology of Syria.

Astatic Needle. A term applied to the magnetic needle when it is withdrawn from the action of the earth's magnetism, and has no longer the *statical* position in which it is in equilibrio with the influence of this force. A needle is rendered astatic by placing the axis about which it is moveable in the direction in which terrestrial magnetism acts, because it cannot then receive any motion from this force, and will rest in any position. This effect is more usually produced by neutralizing the action of the earth by means of an equal and opposite magnetic action; that is, by placing the needle vertically above or below a second magnetic needle the north pole of which is in juxtaposition with the south pole of the first needle. (Brewster, *Treatise on Magnetism*.)

Asteraceæ, so called after *Aster*, one of the most familiar genera, is a name proposed by Lindley for the great family of *Compositæ*.

Asteria. The name used by Pliny to denote the asteriated varieties of Sapphire, or those which display diverging rays of light. [STAR-STONE.]

Asterisk (Gr. *ἀστέριος*). In Diplomats, a sign in the figure of a star, frequently met with in ancient Latin manuscripts, and seeming to serve various purposes; sometimes to denote an omission, sometimes an addition, sometimes a passage which appeared remarkable on any account to the copyist.

Asterism (Gr. *ἀσθήρις*). In Astronomy, denotes a collection of stars. It was formerly used in the same sense as constellation, but is now generally appropriated to any small cluster of stars, whether forming part of a particular constellation, or otherwise.

Asteroids (Gr. *ἀστεροειδής*). A term frequently used by writers on astronomy, to designate the group of small or telescopic planets.

which revolve between the orbits of Mars and Jupiter.

Asthenic (Gr. *ἀσθενής*, from *ἀ* priv., and *σθένος*, strength). Asthenic diseases are those which are prominently marked by great and direct debility.

Asthma (Gr.). A disease, the leading symptoms of which are difficulty of breathing, coming on at intervals, accompanied with cough, and more or less expectoration. The fit most frequently occurs in the night during the first sleep, suddenly awaking the patient, and lasting for three or four hours or more. It is a terrible, but in itself rarely a fatal, disease, though it often lays the foundation of organic mischief. Its proximate cause has not been very clearly ascertained.

Astigmatism (Gr. *ἀ* priv., *στῖγμα*, a mark). In Optics, the name given to a peculiar defect in the eye, which consists in its refracting the rays of light differently in different planes. The defect may be detected by looking at a small pin-hole in a card, held up against the sky or any bright object, and moved to different distances from the eye. In the case of ordinary eyes the image of the hole remains circular at all distances, but to an eye having the peculiar defect in question the image of the hole, as the card is moved away from the eye, becomes elongated in a particular direction, and at a certain distance passes into a straight line. On moving the card still farther from the eye it becomes elongated in a direction perpendicular to the former, and again at a certain distance (the second limit of distinct vision) it passes into a straight line. This imperfection may be corrected by means of a cylindrical, or spherocylindrical, lens, the distances of the card from the eye when the two focal lines are formed giving the means of calculating the required curvature of the cylindrical surface. (See *Transactions of the Cambridge Philosophical Society* for 1829; *Reports of the British Association* for 1849.)

Autonomous (Gr. *ἄνομος*, from *ἀ* priv., and *νόμος*, a mouth). A term applied to certain mooses whose theca has no aperture.

Astræa (Lat.). One of the recently discovered small planets circulating between the orbits of Mars and Jupiter. Astræa was discovered on December 8, 1845, by Hencke of Driessen, in Prussia, who had for several years previously been engaged in astronomical observations directed to the discovery of such a body. The announcement of his success excited great interest among astronomers, no other addition having been made to the planetary system since the discovery of Vesta by Olbers in 1807; but nine others belonging to the same group have since been added to the number. Astræa appears as a small star of the ninth magnitude. Its mean distance from the sun is 2.677 times that of the earth, and it completes its revolution in 1,611.095 mean solar days. Unlike the four others previously discovered in the same region, the inclination of its orbit was found to be only $5^{\circ} 19' 22.7''$, which is

less than the inclination of Mercury, and consequently the term *ultra-sodiacal* is no longer applicable to the whole group. This distinction also belongs to three of the others since detected, viz. Flora, Iris, and Metis. Hebe, also discovered by Hencke, has an inclination of nearly 15° . [PLANET.] See the list of recently discovered planets in ASTRONOMY.

ASTRÆA. A genus of Anthozoa; the polypary or calcareous skeleton of which is characterised by sessile, star-shaped lamellate cells, crowded upon the upper surface. The species are divided into rayed Astrææ (*Ast. radiate*), with the stars separated from the base; and toothed Astrææ (*Ast. denticulate*), with the stars contiguous.

Astragal (Gr. *ἀσπράγγος*). In Architecture, a convex moulding which was originally introduced at the base of the capital of the Ionic order, and has since been applied in other positions. It is usually accompanied by some small fillets, and is in some cases ornamented, as in the arch of the Goldsmiths at Rome, where it is carved with a series of leaves and reeds bound together, and on the base of Trajan's column; sometimes it is ornamented with a bead and reel, as in the majority of examples which occur in Grecian and Roman architecture.

Astragalus (Gr. *ἀσπράγγος*). The ankle bone. The ancients used the corresponding bones of animals as substitutes for dice.

ASTRAGALUS. In Botany, a rather extensive family of herbaceous Leguminous plants, including a few shrubby species. The most interesting are those which yield the gum-like substance called *tragicanth*, which is the produce of several dwarf spiny shrubs, e.g. *A. gummifer*, *strobiliferus*, and *versus*, growing in Kurdistan, Persia, Asia Minor, &c. The gummy matter exudes from their stems.

Astrakanite. A hydrous sulphate of magnesia occurring in imperfect prismatic crystals, in the salt lakes of Astrakan, east of the mouth of the Volga.

Astrolabe (Gr. *ἀστρολάβος*). A circular instrument used for taking or observing the stars. The ancient astrolabe consisted of two or more circles, having a common centre, and so inclined to each other as to enable the astronomer to observe in the planes of different circles of the sphere at the same time. For example, if the circles were at right angles, the instrument would give both longitude and latitude, or the right ascension and declination of a star. The equatorial, the altitude and azimuth instrument, and the theodolite, are instruments which answer the same purpose as the ancient astrolabe. Ptolemy changed the form of the ancient instrument, and reduced it to a plane surface, to which he gave the name of planisphere; and from this circumstance the term astrolabe has been used in modern times to denote a planisphere, or stereographic projection of the sphere on the plane of one of its great circles.

Astrology (Gr. *ἀστρολογία*). According

ASTROLOGY

to its derivation, this term should signify the science or knowledge of the stars. Originally, the terms astrology and astronomy were used indifferently in the same sense; but for a long time the former has been employed to denote the vain and superstitious study of predictions and horoscopes; while the latter has been reserved to denote the true science of the celestial motions. According to Lalande, this distinction began to be observed in the time of Clement of Alexandria, that is, in the second century. Astrology is generally coupled with the epithet judicial, from the judgments drawn from it relative to future events.

Judicial astrology is supposed to have had its origin in Chaldea, whence it passed into Egypt, Greece, and Italy. The desire of penetrating into futurity is so congenial to the human mind, that this pretended science has found favour in all ages and countries; and it is a remarkable fact, that astronomy, which demonstrates the frivolity and absurdity of its predictions, was long indebted to it for the principal part of its own progress. Kepler, in the preface to the Rudolphine Tables, observes, that astrology, though a fool, was the daughter of a wise mother, to whose support and life the foolish daughter was indispensable. At the present day it is only among the most ignorant vulgar, or the unenlightened tribes of Asia and Africa, that astrology is held in esteem; but the triumph of sound science and the spirit of philosophy has been slow and difficult. So late as the year 1705, the conductor of *La Connaissance des Temps* thought it necessary to apologise for the absence of all predictions in that astronomical work, by stating, that the Academy had never recognised the solidity of the rules which were given by the ancients for discovering the future by the configurations of the stars; and, what is still more surprising, the first lunar tables calculated according to the Newtonian theory were intended to be subservient to the calculation of nativities.

Astrological predictions are founded on the positions or aspects which the sun, moon, and planets have relatively to each other at the moment of birth, or some other critical period of a person's life, and on certain arbitrary influences supposed to belong to each of those bodies. For the purpose of facilitating the determination of the aspects, the whole heaven, visible and invisible, is divided into twelve equal parts by the horizon, the meridian, and four other circles passing through the north and south points of the horizon, and the points of the equator (or rather the prime vertical, or sometimes the ecliptic, for the practice was not uniform), which are at the distance of 30 and 60 degrees from the meridian. These equal spaces are called the twelve houses of the heavens, and the circles by which they are circumscribed are called circles of position. The circles of position are supposed to remain fixed, so that a celestial body is carried through each of the twelve houses in the course of a day by the diurnal rotation. The first house

is contained between the eastern horizon and the next circle of position, going to the eastward; consequently the seventh will commence with the western horizon, and the tenth with the meridian or culminating point of the ecliptic. The beginning of the first house, or the point of the ecliptic just rising, is called the horoscope. The first house is the house of life; the second, of riches; the third, of brothers; the fourth, of parents; the fifth, of children; the sixth, of health; the seventh, of marriage; the eighth, of death; the ninth, of religion; the tenth, of dignities; the eleventh, of friends; and the twelfth, of enemies. Each of the houses has one of the heavenly bodies as its peculiar lord. They have also different powers, the strongest of all being the first, and the next in power the tenth; so that if two planets are equally powerful, *ceteris paribus*, that will prevail which is in the stronger house.

Having made the preliminary arrangement of the heavens, the next object is to consider the aspects or configurations of the influential bodies. Aspect, as defined by Kepler, is the angle formed by the rays proceeding from two planets, and meeting at the earth, and which have the property of producing some natural influence. The ancients reckoned five aspects, namely, the conjunction denoted by the character \odot , the opposition by \otimes , the trine by Δ , the quadrile by \square , and the sextile by \times . These names and characters, besides several others added in more recent times, are retained in our almanacks to the present day. In the aspect of conjunction the angle made by the two planets is 0° ; in the opposition it is 180° . The trine is the third part of a circle, or 120° ; the quadrile is 90° , and the sextile 60° . With regard to the influences of the aspects, they are benignant, malignant, or indifferent. The quadrile and opposition are considered as malignant or adverse; the trine and the sextile as benignant or propitious; and the conjunction an indifferent aspect.

It now remains only to ascribe certain influences to each of the planets, and to suppose all animals, plants, countries, &c. subject to their control, in order to obtain an idea of the nature of the astrological art. The influences ascribed to the planets were of course as arbitrary as those ascribed to the aspects. Saturn being at the greatest distance from the sun was supposed to be of a cold nature; Jupiter, Venus, and the Moon, temperate and benignant. Saturn and Mars were the most dangerous. The Sun and Mercury participated in the properties of the one and the other, according to circumstances. But these influences were exerted in an infinite number of ways, according to the houses which the planets happened for the time to occupy.

It would be superfluous at the present day to adduce any serious argument against a system of imaginary influences and arbitrary rules, having no other foundation than the ignorance and superstition of mankind, and contradicted

by every result of true science, and every dictate of common sense. The celestial bodies pursue their courses in obedience to unalterable laws; and the legitimate business of the philosopher is to discover those laws, to trace out their consequences, and to apply the results of his discoveries to the well-being of humanity.

Astrometer (Gr. *ἀστρον*, a star; *μέτρον*, measure). The name given by Sir John Herschel to an instrument invented and employed by him for comparing the intensities of light of the stars one with another by the intervention of the moon, or the planet Jupiter, or some other natural standard, no invariable standard of artificial light having yet been discovered. It is necessary that the intermediate standard of comparison be brighter than any of the stars to be compared, so as to allow of being equalised with them by a reduction of its light optically effected, and at the same time either invariable, or at least variable in such a manner that its changes can be calculated and reduced to numerical estimation. Jupiter being brighter than any of the stars, subject to no phases, and variable in its light only by the variation of its distance from the sun, may be considered as best fulfilling all the conditions. 'The process,' says Sir John, 'consists in deflecting the light of the moon by total internal reflexion at the base of a prism, so as to emerge in a direction exactly coincident with that of the undeflected light of one of the stars to be compared. It is then received upon a lens of short focus, by which the image of the moon is formed, which, viewed at a considerable distance by an observer placed in or near the axis of the lens, will appear to him as a star. This artificial star is then to be approached to or removed from the eye until its light is judged to be exactly equal to that of the real star, which, lying in nearly the same direction from the observer, will be seen side by side with the artificial one by the same eye, or with both eyes at once, without the aid of a telescope, in the ordinary mode of natural vision. The distance of the eye from the focus of the lens being then measured, the prism and lens are to be placed so as to form another similar artificial star in a direction nearly coincident with that of the other star under comparison; and another equalisation being made and distance measured, it is obvious that the intensities of the lights of the two stars, or at least their effects on the retina under the circumstances of comparison, will be to each other in the inverse ratio of the distances so measured respectively.' (*Results of Astronomical Observations*, &c., p. 363; also *Outlines of Astronomy*.)

It may be noticed that the name *Astrometer* was given by Bouguer to the Heliometer, or object-glass micrometer. It was also given by Jéaumont to an instrument for finding the rising and setting of the stars and their position, which he has described in the *Mémoires* of the Academy of Sciences of Paris. An improved

instrument for the same purpose is described in the *Edinburgh Encyclopædia*, art. 'Science.'

Astronomy (Gr. *ἀστρονομία*). The science which treats of the motions, distances, arrangement, and magnitudes of the celestial bodies; of their constitution and physical condition, and, in general, of whatever can be known respecting them.

There is no branch of human knowledge of which the results appear at first sight more at variance with the impressions of our senses. The first aspect of the heavens leads us almost irresistibly to imagine ourselves placed in the centre of a starry sphere; which, in its diurnal revolution, carries along with it all the heavenly bodies. But the changes of relative position which some of the most remarkable among them continually undergo, soon make it evident that they do not all belong to the same sphere. Further observation and reflection lead us to conclude that the apparent daily revolution of the firmament is merely an illusion occasioned by the diurnal rotation of our own earth, which, instead of remaining fixed at the centre, is carried forward about the sun with a velocity of about 10 miles in a second of time, or four times that of a cannon-ball when it leaves the mouth of a cannon. The sun, which appears to be of very moderate dimensions, is a body whose volume is 1,384,470 times greater than that of the earth, and distant from it about 93,000,000 of miles. The stars, which even in the best telescope appear only as luminous points, are bodies of the same nature as the sun; many of them, probably, far surpassing it in magnitude.

Different Classes of Heavenly Bodies.—By far the greater part of the celestial bodies appear to be fixed in the firmament, and to preserve invariably the same relative positions. These are the *fixed stars*. A second class comprehends a small number which are continually shifting their positions among the stars, and are perceived to accomplish a complete revolution of the sphere in stated intervals of time. Hence they were called *Planets*, that is, *wandering stars*, from the Greek *πλανήτης*, a wanderer. They describe orbits, very nearly circular, about the sun. Some of them are accompanied by smaller bodies revolving round them (as the moon revolves round the earth), called *Satellites*, or attendants. A third class comprehends bodies differing greatly from those now mentioned, and sometimes exhibiting very extraordinary appearances. These are the *Comets*. Like the planets they are obedient to the attractive force of the sun; but the orbits which they describe are exceedingly elongated, and they are only visible to us when they are near the sun. Hence they appear at distant or uncertain intervals, and only for a short time; and consequently their physical nature is very imperfectly known. The sun, planets, satellites, and comets form a system of which all the members are connected with and act upon one another in obedience to the law of universal gravitation. [See *PLANETS*,

ASTRONOMY

SATELLITES, SUN, and the other terms, in their respective places.]

Divisions of Astronomy.—The first object of the astronomer is to ascertain, with all possible precision, the apparent places of the stars, or their projections on the sphere, in order to obtain an accurate knowledge of their apparent motions and periods. But it is not enough to have ascertained their positions and motions; the results of observations made at different places and distant times must be compared, in order that we may be enabled to distinguish the movements which are real from those which are only apparent, and depend on our own position with regard to objects observed. And when the real paths described by the different bodies have thus been determined, we are next led to investigate the causes of the phenomena, and the expressions of the mechanical forces necessary to produce them. Hence, the science of astronomy may be divided into *practical, rational, and physical*: the first embracing all that is necessary for determining the apparent motions; the second being devoted to the real motions; and the third to the physical causes by which the different motions are regulated and perpetuated.

Practical Astronomy.—In order to determine the positions and motions of the celestial bodies, it is necessary to have the means of measuring time and space with the utmost precision. But neither time nor space can be measured without the aid of very refined instruments and contrivances. Hence, the theory of instruments, the method of using them, and the determination of the different corrections that must be applied in order to free the observed positions from the various instrumental and physical errors by which they are affected, belong to this division of the science. A complete knowledge of the sphere and its various circles, as also of the methods of spherical trigonometry, is requisite to the practical astronomer. Observation gives him the place of a star only with reference to his own zenith, or horizon, or to another star whose place is already determined. But their positions must be reduced; that is, referred to invariable planes or circles, in order that the observations made in different places may be capable of comparison with one another. Without such reductions, the observations are of no use.

Rational Astronomy.—This division includes the determination of the real orbits, and the laws of motion which the different bodies observe, and the construction of hypotheses by the aid of which we may calculate the positions in advance. In the infancy of astronomy, and before observations became very numerous, or were made with precision, various hypotheses were invented to explain the apparent motions. Thus Ptolemy explained the inequalities of the planetary motions, by supposing each of the planets to describe a circle about a centre moving uniformly round the earth in the circumference of another circle. Tycho Brahe

supposed the planets to revolve in circular orbits about the sun, and the sun, accompanied by the planets, to revolve round the earth. Copernicus supposed the earth, as well as all the other planets, to revolve in circular orbits around the sun. All these hypotheses served to explain the phenomena that were known at the time they were respectively invented; and have been successively exploded by more accurate observations, which have proved that the planetary orbits are not circles but ellipses, having the sun in the focus which is common to all of them.

Physical Astronomy.—By this term is generally understood the application of mathematical science to the investigation of the laws by which the motions of the celestial bodies are regulated, the nature of the forces by which their motions are maintained, and the effects of their action on one another. By comparing the momentary deflection of the moon's orbit from a straight line with the effects of terrestrial gravity, as manifested in the descent of falling bodies near the surface of the earth, Newton found that both the phenomena were produced by one and the same cause, and that the moon is retained in her orbit by the attraction of the earth. Subsequent investigations, founded on the general laws of the planetary motions, discovered by Kepler, led him to the conclusion, that a force of the same nature extends through the universe; and that all bodies in the heavens and on the earth gravitate towards each other with forces directly as their quantities of matter and inversely as the squares of their distances. By this single principle he explained the elliptic motions of all the planets and satellites, and the facts which relate to their figures, rotation, and the position of their axes. The calculation of the disturbing forces, or of the effects produced by the mutual attractions of all the bodies in the solar system, forms the most difficult and the most important problem ever submitted to mathematical analysis.

The state of perfection to which astronomy is now brought, may be regarded as the greatest triumph of human exertion and reason. The motions of the moon and the planets are known with the utmost accuracy; and the tables have all the precision which the navigator or practical astronomer can desire. Our knowledge of the planetary system is tolerably complete. That of the sidereal heavens must always be limited by the optical powers of the human eye and the telescope. In this department of astronomy a boundless field has of late years been thrown open for future research and speculation. Stars are observed revolving about one another in elliptic orbits. Are they then connected with each other by forces of the same nature, and observing the same laws, as solar attraction? The periodic times, and consequently the mean distances of one or two comets, are observed to be diminished. Are we then to infer that the regions of space are filled with matter of sufficient density to resist

ASTRONOMY

the motions of comets? Are the comets themselves permanent bodies; or are they merely formed by the occasional collapse, as it were, of nebulous matter, and again dissipated after a few revolutions? The resistance of the ether, the nature of comets, the constitution of the nebula, the laws which regulate the formation and motions of sidereal systems: such are the questions (questions remote indeed from any practical application to the affairs of mankind) which astronomers now aspire to solve.

Among the recent discoveries in astronomy, the most prominent, and in some respects the most remarkable ever made in the science, is that of the new planet, to which the name of Neptune has been given, beyond the orbit of Uranus. In all previous instances of the discovery of a new planet, the discovery was accidental, in so far as the existence of the body was not foreknown, or even suspected, until its true nature became revealed by the observation of its relative motion. In the present case, not only had the existence of the planet been made known through the effects of its attraction, but the precise spot which it occupied in the heavens had been indicated by the results of a profound theoretical investigation, and the planet was immediately recognised on directing a telescope upon the spot so indicated.

By a singular coincidence, though not without example in the history of discovery, the problem was undertaken about the same time by two distinguished mathematicians, Mr. Adams in England, and M. Leverrier in France, neither having the slightest knowledge of the attempt of the other; and both arrived at a correct conclusion. Mr. Adams's results, however, though communicated to two or three astronomers, were not published or generally known until some time after the actual discovery of the planet, and, as it happened, did not contribute in any way to that discovery. Those of M. Leverrier were given to the Academy of Sciences at Paris, and published in the *Comptes Rendus*; and by their means the planet was found by Dr. Galle, of Berlin, on the very day on which his attention was directed to them, within less than a degree of its predicted place. This memorable discovery took place on September 23, 1846, and was hailed by every astronomer of Europe as the most signal triumph of theory which had ever been achieved.

Neptune is attended by at least one satellite, probably two, and is suspected to resemble Saturn, in having also a ring. Its position in the ecliptic, since the date of its discovery, has been unfavourable to its being distinctly seen.

The next most remarkable feature in the recent progress of astronomy is the discovery of a large number of new planets belonging to the group which circulate between the orbits of Mars and Jupiter. Their names, with those of their discoverers, and the dates of their respective discoveries, are as follow:—

195

Name	Date of Discovery	Discoverer
Flora	1847, October 18	Hind.
Melpomene	1852, June 24	Hind.
Victoria	1850, September 18	Hind.
Euterpe	1853, November 8	Hind.
Vesta	1807, March 29	Obers.
Iris	1847, August 13	Hind.
Metis	1848, April 25	Graham.
Urania	1854, July 22	Hind.
Phocæa	1853, April 6	Chacornac.
Masilla	1852, September 19	De Gasparis.
Hebe	1847, July 1	Hencke.
Lutetia	1852, November 15	Goldschmidt.
Fortuna	1852, August 22	Hind.
Parthenope	1850, May 11	De Gasparis.
Theïs	1852, April 17	Luther.
Fides	1855, October 5	Luther.
Amphitrite	1854, March 1	Marth.
Astræa	1845, December 8	Hencke.
Pomona	1854, October 26	Goldschmidt.
Egeria	1850, November 2	De Gasparis.
Irene	1851, May 19	Hind.
Thalia	1852, December 15	Hind.
Eunomia	1851, July 29	De Gasparis.
Proserpine	1853, May 5	Luther.
Circæ	1855, April 6	Chacornac.
Juno	1804, September 1	Harding.
Leda	1856, January 12	Chacornac.
Ceres	1801, January 1	Piazzi.
Pallas	1802, March 28	Obers.
Atalanta	1855, October 5	Goldschmidt.
Bellona	1854, March 1	Luther.
Polyhymnia	1854, October 28	Chacornac.
Lenæthea	1855, April 19	Luther.
Calliope	1852, November 15	Hind.
Psyche	1852, March 17	De Gasparis.
Themis	1853, April 5	De Gasparis.
Hygeia	1849, April 12	De Gasparis.
Euphrosyne	1851, September 1	Ferguson.
Letitia	1856, February 8	Chacornac.
Harmonia	1856, March 31	Goldschmidt.
Daphne	1856, May 22	Goldschmidt.
Isis	1856, May 23	Pogson.
Ariadne	1857, April 16	Pogson.
Nysa	1857, May 27	Goldschmidt.
Eugenia	1857, June 28	Goldschmidt.
Hestia	1857, August 16	Pogson.
Pseudo-Daphne	1857, September 9	Goldschmidt.
Aglaia	1857, September 15	Luther.
Doris	1857, September 19	Goldschmidt.
Palas	1857, September 19	Goldschmidt.
Virginia	1857, October 4	Ferguson.
Nemausa	1858, January 22	Laurent.
Europa	1858, February 6	Goldschmidt.
Calypso	1858, April 4	Luther.
Alexandra	1858, September 10	Goldschmidt.
Pandora	1858, September 10	Searle.
Mnemosyne	1859, September 22	Luther.
Concordia	1860, March 24	Luther.
Danaë	1860, September 12	Chacornac.
Titania	1860, September 9	Goldschmidt.
Erato	1860, September 14	Ferguson.
		Dr. Förster.
Ausonia	1861, February 11	M. Lœwe.
Angelina	1861, March 6	De Gasparis.
Maximiliana	1861, March 10	Tempel.
Maia	1861, April 10	Tempel.
Asia	1861, April 18	Tuttle.
Leto	1861, April 29	Pogson.
Hesperia	1861, April 29	Luther.
Panopea	1861, May 5	Schlaparelli.
Feronia	1861, May 29	Goldschmidt.
Niobe	1861, August 13	Peters.
		Luther.

Even in this very brief sketch of the progress of astronomy, the recent application of photography to celestial objects by Mr. Warren de la Rue, and the discovery of the willow-leaf structure of the solar surface by Mr. Nasmyth, must not be omitted. The first appears destined to afford most valuable aid in extending our knowledge of the physical structure of the

o 2

ASYLUM

members of our solar system, whilst the last gives us new and altogether unexpected information regarding the condition of the surface of the sun, the value of which, when taken in connection with the recent physico-chemical discoveries of Bunsen and Kirchhoff relating to the constituents of the sun's atmosphere, can scarcely be overrated. [SPECTRUM ANALYSIS.]

For further information on this extensive and very important science, we must refer the reader to the particular terms which belong to it, and also the general terms, COMET, MOON, PLANET, SATELLITE, STAR, SUN. The physical theory of the planetary motions will be found explained under GRAVITATION; and astronomical instruments described under their respective names. Works on astronomy are so abundant in every European language, that it could serve no purpose to make any references to them in this place.

Asylum (Gr. *ἄσυλον*, from *ἀ* neg., and *συλᾶν*, *I rob*). A place of refuge to which criminal might fly, and from which it was held impious to remove them by force. Their right of protection did not belong to all altars or temples, but was attached by the laws to certain spots in different places. When the privilege was not legalised, any means short of actual violence might be employed to remove men from the sanctuary. The Greek cities possessing this right of asylum had in the time of Tiberius become so numerous, that the senate, for the better administration of justice, greatly reduced their number and restricted their privileges.

The asylum, which Romulus is said to have opened, at Rome, was in later times a spot carefully walled in, which no one was allowed to enter. It is probable that the legend arose from a misinterpretation of the word, by which the inviolability of the spot was transferred to those who might take refuge within it.

In its modern signification, the word means a place set apart for the care and protection of persons who by misfortune or disease may need such help. The most prominent of such places are asylums for the blind, deaf and dumb, lunatics, and the destitute. Few things distinguish a civilised from a savage state of society more than institutions which have for their object the benefit of those who, by moral or physical defects, are incapacitated for the purpose of self-exertion. In the heathen states of Greece and Rome even hospitals were unknown. On the subject of asylums in England and France, the reader will find in parliamentary papers, and in the reports of managers, a mass of information at once amusing and instructive.

Asymptote (Gr. *ἀσύμπτωτος*, *not falling together*). A right line or curve which continually approaches, but never meets, a given curve.

A curve whose ordinates MN are inversely proportional to the corresponding abscissæ ON will clearly approach both axes incessantly but never intersect either, however far it may be produced. A second curve similarly con-

ASYMPTOTE

structed, but having its ordinates $M'N$ twice as long as before, will approach but never meet either the axes or the first curve. Under such

circumstances either curve would be called an asymptote of the other, and both would have the axes for *rectilinear* asymptotes. Two curves, neither of which have infinitely distant points, may also be asymptotic. For instance, suppose a radius OA of a circle to rotate incessantly in the same direction, and in every position a portion AB cut off inversely proportional to the angle it has described. The point B once inside the circle will never be able to leave it again, or even to reach the circumference, which it will incessantly approach. In this case the circle is said to be asymptotic to the spiral described by B .

An algebraic curve of the n^{th} order, although it may have an unlimited number of asymptotic curves, cannot have more than n rectilinear asymptotes, and may have none whatever. In geometrical language, however, a curve of the n^{th} order is always said to have n *real* or *imaginary* asymptotes, the latter being regarded as tangents at the n real or imaginary points where the infinitely distant right line intersects the curve. Thus viewed, the determination of the asymptotes of a curve is merely a particular case of the more general problem, to find the tangents at the n points in which a curve of corresponding order is cut by any given right line.

A parallel to an asymptote must cut the curve in an infinitely distant point, and conversely a line which does so cut a curve must be parallel to an asymptote. This circumstance leads at once to a simple method of finding the *directions* of the asymptotes. In fact, the terms of the highest (or n^{th}) dimension in the equation to the curve, when equated to zero, represent the n real or imaginary right lines through the origin which are parallel to the n asymptotes. The directions of the asymptotes being thus known their actual positions can be easily determined. In fact, the equation of the curve being written in the form

$$x^n \phi_n\left(\frac{y}{x}\right) + x^{n-1} \phi_{n-1}\left(\frac{y}{x}\right) + \&c. \dots = 0$$

where in general $\phi_n(a)$ indicates a function of a of the n^{th} degree, and the equation of the required asymptote in the form

$$y = ax + b,$$

a will be one of the roots of the equation $\phi_n(a) = 0$, and the b which corresponds to it

will have the value $\delta = -\frac{\phi_2 - 1(a)}{\phi_1'(a)}$ where ϕ_1' denotes the first derived function of ϕ_1 .

Asymptotic Cone. A tangent cone to a surface whose curve of contact is situated in the plane at infinity. The asymptotic cone of a central quadric $Ax^2 + By^2 + Cz^2 = 1$ is represented by the equation $Ax^2 + By^2 + Cz^2 = 0$; that is to say, it has its vertex at the centre of the quadric, and has the same axes and cyclic planes as the latter surface. Its focal lines are the asymptotes of the focal hyperbola of the quadric. [CYCLIC PLANES, FOCAL LINES, &c.]

Asymptota (Gr. *ἀσύνδετος*, from *ἀ* neg., and *συνάπτω*, I connect). In Grammar, sentences irregularly or ungrammatically connected.

Asyndeton (Gr. *ἀσύνδετος*, from *ἀ* neg., *συνάπτω*, I connect). In Rhetoric, a figure by which the conjunctions in a sentence are omitted: as in the famous phrase of Cæsar, 'Veni, vidi, vici.'

Atacamite. A hydrated oxychloride of copper, originally obtained from the Atacama Desert, between Chili and Peru.

Atë (Gr.). In the Mythology of Homer, is the spirit of Mischievous Folly. As such, she is hurled out of heaven by Zeus for postponing the birth of Hercules to that of Eurystheus. Before the time of Æschylus, the word had passed into the meaning of a Fate or Doom, resting on a house, after the shedding of innocent blood.

Atèles (Gr. *ἀτελής*, imperfect). A genus of South American monkeys, characterised by the absence or rudimental condition of the thumb of the anterior hands. The deterioration of these members as prehensile organs is compensated by a very efficient prehensile tail.

Atellane Fabulæ (Lat.). Rustic comedies which had their origin among the Oscan inhabitants of Campania, from a town of which country, Atella, they derived their name; they are of some importance in the early history of the Latin stage.

A Tempo Giusto (Ital. in correct time). In Music, a direction to the performer, generally after a recitative, to keep the measure true and correct, which, during the recitative, was performed irregularly, to suit the action and passion of the scene.

Athalamous (Gr. *ἀ*, without, and *θάλαμος*, a chamber). Lichens whose thallus is not furnished with shields or beds for the spores; in these the reproductive matter is supposed to be dispersed through the substance of the crust, as in *Leparia*.

Athamantine. A crystallisable substance contained in the root of the *Athamanta* (now *Peucedanum*) *Oreocelinum*.

Athanasian Creed. A confession of faith, described in the rubric of the Common Prayer Book, which appoints it to be read on certain days, as commonly called the Creed of St. Athanasius. That it was really composed by that father is more than doubtful: modern divines seem generally to assent to the judg-

ment of Waterland, who considers it to have been written by Hilary, bishop of Arles.

Athanor. A term applied by the alchemists to a furnace so constructed as to supply itself with fuel.

Atheling or **Ætheling** (A.-Sax.). A name given among the Anglo-Saxons to the heir apparent or presumptive to the crown.

Athēna or **Athēnē**. [MINERVA.]

Athenæum (Lat.). A school under this name was founded at Rome by the emperor Hadrian, and appears to have been long an important institution. Another foundation under the same name existed at Lyons.

Athereasite. An altered Scapolite, which it resembles both in form and appearance. It is green and opaque, and is found at Arendal in Norway.

Atheriogra (Gr. *ἀθήρ*, a point, and *γράφω*, a horn). The name given by Cuvier and Latreille to one of the primary divisions of the Dipterous order of insects. It comprehends the modern families *Syrphida*, *Astrida*, *Conopida* and *Muscida*, in all of which the antennæ have only two or three joints, the last being furnished with a bristle.

Atherina. A Linnæan genus of Abdominal fishes, having an elongated body, two widely-separated dorsal fins, and a very protractile mouth armed with very small teeth. All the known species have a broad silvery band along each side, and six branchiostegal rays. It was to the fishes of this genus that the ancients attributed an origin by equivocal generation; and the inhabitants of the shores of France which are washed by the Mediterranean still call them 'nonnats.'

Athermanous (Gr. *ἀ* priv., and *θερμός*, heat). Transparent or translucent substances which resist the passage of radiant heat.

Atheroma (Gr.). In Medicine, a soft tumour, generally contained within a cyst or bag.

Atherospermaceæ (Atherosperma, one of the genera). Incomplete aromatic Exogenous shrubs found in New Holland and South America, remarkable for having their flowers in a cup-shaped involucre, and the peculiar anthers of *Lauracea*.

Athletes (Gr. *ἀθλητής*, from *ἀθλος*, a contest). Men who contended at the public games of the Greeks and Romans, in boxing, wrestling, running, leaping, and throwing the quoit. The name was more particularly applied in the two former cases. They fought naked, having had their bodies previously anointed by the *Alipste*. The boxers used a kind of glove called *cæstus* or *cestus*, which consisted of leather thongs wrapped round the hand and loaded with pieces of lead and iron, to give greater weight to the blows.

Among the Greeks these contests were considered highly honourable, and the victors at their national games at Olympia, and elsewhere, were received in their native states with great distinction. The special attribute of Polydeukes, or Pollux, one of their most

ATLANTES

popular deities, was his skill in wrestling. Among the Romans the athletes were trained persons, hired from the lower ranks, or slaves and foreigners.

Atlantes. A name given by Vitruvius to the male figures which were introduced, instead of columns, to support the cornices of a building, such as that in the temple of Jupiter Olympus at Agrigentum.

Atlantic Ocean. This portion of the great ocean extends from the Arctic to the Antarctic Circle, but the part fairly enclosed by land on both sides is about 7,000 miles in length. Its breadth, which is less than 1,000 miles between Greenland and Norway, extends to 1,800 miles at the equator, and is about 4,000 miles at its greatest width between Florida and the coast of northern Africa. Its area is estimated at 27 millions of square miles.

The opposite coasts of this great canal correspond in their general outline. Those on the east side are remarkable for their indentations, and on both sides the inland seas and gulfs are more considerable than in the same distance in other parts of the world. The total length of coast line is estimated at 55,300 miles. The drainage area connected with this ocean is extremely large, but the great rivers are confined to the American side.

Many parts of the Atlantic are very deep, but the general form of the sea bottom is that of a large trough descending by successive plateaus and not by gradual slopes.

Several of the most important inland seas open into the Atlantic. On the European side are the Baltic and the Mediterranean, the latter including the Black Sea. On the opposite side are Hudson's and Baffin's Bay, the Gulf of Mexico, and the Caribbean Sea.

Atlantides (Gr.). In Astronomy, a name given to the Pleiades, because they were supposed to be daughters of Atlas, or his brother Hesperus, who were translated to heaven.

Atlantis (Gr.). An island mentioned in Plato's Dialogue entitled 'Timæus,' as having once existed in the Atlantic Ocean opposite to the Pillars of Hercules. It was said to have exceeded Europe and Africa jointly in magnitude; and after existing for 9,000 years to have been submerged in the ocean. The question of the reality and site of this island has been frequently discussed by modern geographers. M. Bailly supported the Platonic view, and cited Homer and Diodorus Siculus in corroboration of his opinion. Rudbeck, Kircher, Beckman, and others, concur in opinion respecting its reality, but each assigns to it a different locality. According to the conjectures of Buffon and Whitelurst, who regarded the Canaries and the Peak of Teneriffe as the summits of mountains belonging to some submerged continent, Atlantis was the land which, at a former period, united Ireland to the Azores and the Azores to America. On the other hand, D'Anville and Heeren, and Plato's account of the Atlantis as altogether a fanciful speculation: while many discover in it

ATMOMETER

proofs that the American continent was known at some remote period to the people of the Eastern hemisphere.

Atlas (Gr.). In Anatomy, is the term applied to the uppermost of the cervical vertebrae; so named from its supporting the head, as Atlas was supposed to support the heaven.

ATLAS. In Mythology, a son of Iapetus and Clymene, or of Æther and Gaia, and brother of Prometheus. He bore up the heavens on his head and hands. Hesiod. *Theogony*, 507 &c.

ATLAS. A rich kind of satin, manufactured in India. It was formerly in great demand, but is now little used.

Atlas Mountains. A broad belt of mountain land, extending parallel to the north coast of Africa and separating the Mediterranean from the low lands of the desert of the Sahara, has been known from classical times by this name. As a mountain system it consists of three parts; the Greater Atlas, which is the innermost and loftiest range; the Lesser Atlas, which is a coast range; and the Middle Atlas, chiefly a rich table land.

The Greater Atlas extends from the Atlantic coast to the Lesser Syrtis, and forms an important mountain knot in Morocco, rising to a height of 15,000 feet and covered with perpetual snow. Further to the east the chain, though lofty, is below the snow line during the middle of summer.

The Lesser Atlas commences at Capo Spartel opposite Gibraltar, and runs due east at a great elevation till it dies away in the plains of the desert towards Egypt. A long rugged chain forms the African coast opposite Spain, and is covered with snow during many months of the year. The intervening country is partly table land and partly mountain, but is for the most part rich and capable of cultivation.

Atmidometer. Babington's atmidometer is an instrument for measuring the evaporation from water, ice, or snow. It consists of an oblong hollow bulb of glass or copper, beneath which, and communicating with it by a contracted neck, is a second globular bulb, duly weighted with mercury or shot. The upper bulb is surmounted by a small glass or metal stem, showing a scale graduated to grains and half grains; on the top of which is fixed horizontally a light, shallow metal pan, of about five inches area. This instrument being immersed in a vessel of water, through a circular hole in the cover of which the stem rises, distilled water is gradually poured into the pan above, which is thus caused to sink, until the zero of the stem is brought to a level with the cover of the vessel. Thus adjusted, as the water in the pan evaporates, the stem ascends, and the amount of evaporation is indicated in grains. These indications are the only satisfactory means we possess of measuring evaporation from ice or snow. An adjustment for temperature is furnished with the instrument.

Atmometer (Gr. ἀτμός, vapour, and

ATMOSPHERE

μέτρον, measure). An instrument for determining the rate of evaporation from a humid surface.

Atmosphere (Gr. *ἀτμός, vapour, and σφαῖρα, a sphere*). The assemblage of gases and vapours which form the invisible medium surrounding the earth. For an account of the different gases which enter into the composition of atmospheric air, see *AIR*. We shall here confine ourselves to the mechanical properties of the atmosphere.

Weight of the Atmosphere.—It is well known that the rise of water in the sucking pump, and the retention of the column of mercury in the barometric tube, are caused by the pressure of the atmosphere; we have therefore, in either of these phenomena, the means of measuring its weight. The column of mercury in the tube of a barometer is exactly equal in weight to a cylinder of air of equal diameter reaching to the top of the atmosphere. A column of mercury whose base is a square inch, and height the mean height of the barometer, weighs 14·6 lbs. avoirdupois nearly; so that the atmosphere exerts a pressure equal to 14·6 lbs. on every square inch at the surface of the earth.

This pressure of the atmosphere plays a very important part in the animal and vegetable economy. Like that of all other fluids, it is exerted equally in all directions; thus the air in a tube presses not only on the bottom but also on the sides of the tube, with a force equal to 14·6 lbs. for every square inch. The surface of a man of ordinary stature is about 16 square feet, or 2,160 square inches, whence the whole atmospheric pressure which his body sustains amounts to the enormous sum of 31,636 lbs. This great pressure is not sensibly felt, because it is balanced by the reaction of the elastic fluids in the interior of the body; but if the equilibrium were to be suddenly destroyed, the consequences might be fatal. Under the exhausted receiver of an air-pump, animal life is soon destroyed; on the summit of a very high mountain a man experiences extreme fatigue, the pulse is accelerated, and sometimes blood starts from some of the tender parts of the body, in consequence of the diminished pressure.

Density of the Atmosphere.—The density of the atmosphere is not the same at different distances from the surface of the earth, but diminishes with the altitude in a complex ratio.

Height of the Atmosphere.—There are various methods of obtaining an approximate estimate of the height of the atmosphere. One of them, proposed by Kepler, is derived from observations on the twilight, which is occasioned by the power the atmosphere possesses of refracting and reflecting light. It is generally assumed that twilight ceases when the sun has descended 18° below the horizon. Now it may be considered that this takes place when a ray of light proceeding from the sun, and passing by the surface of the earth, just reaches the highest stratum of the atmosphere, and is

ATMOSPHERIC RAILWAY

reflected back to the earth in the direction of a tangent to its surface at the place of observation. On this principle it is calculated that reflection cannot take place at a greater altitude than 45 miles. There are various considerations which lead us to infer that the height of the atmosphere cannot be much less than this, whilst there are others which render it highly probable that the extreme altitude is much greater. Though we are unable to assign the precise boundaries of the atmosphere, there are phenomena which indicate that it has a limit, and that it does not extend indefinitely into the celestial spaces, but belongs exclusively to our earth.

Effects of the Atmosphere on Light.—Like all other diaphanous substances, the atmosphere deflects oblique rays of light from their rectilinear course. This phenomenon is called refraction. It increases the apparent elevation of all the celestial bodies above the horizon; but, fortunately for astronomy, its effects can be rigorously calculated. The atmosphere also, notwithstanding its transparency, intercepts and reflects the rays of light, or objects would not be illuminated unless exposed to the direct light of the sun. The illuminating power of the atmosphere is so feeble, that to an eye placed in the shade the stars are visible in broad day.

The colour of the gas or air which composes our atmosphere is blue. The tint is, however, so slight that it cannot be appreciated by the eye unless clouds are absent and a mass of it several miles thick be viewed at once.

Atmospheric Railway. A system of propulsion which has been resorted to on some railways, in which motion is given to the carriages by connecting them with a piston rod, which in its turn is moved by the diminished pressure of the air on one side of a cylinder; the piston moves along a tube which runs parallel to the railway, and the success of the system depends upon the degree of perfection attained in securing the closing down of the joint, through which the connecting rod passes; for evidently the perfection of the vacuum must be, in the end, regulated by the power of the air-pump to maintain the diminished pressure on the front.

In the Atmospheric Railways of England and France, the system consists in placing along the length of the railway a large cast-iron tube, in which a piston moves bearing a rod, to which is fixed the wagon, by a bar. A longitudinal groove is left in the upper part of this tube to give passage to this bar; and the piston being set in motion drags it along the groove, and gives motion to the train. The groove is covered by a valve, which is raised to allow the bar to pass, and is then closed. A stationary air-pump creates a vacuum in the great tube upon one side of the piston, which is then urged forwards by the pressure of the air on the other side; the tube is closed at both ends. The valve is composed of leather, with stiffening pieces of iron rivetted

ATMOSPHERIC STONES

through, and is fixed to the seating by an iron bar, is compressed upon the seating by a rod which follows the piston, and is soldered with a species of grease consisting of wax and tallow. Special appliances are required for the passage from a main line to a siding, as in stations, and for the passage of level crossings, which have been met with considerable success, but which nevertheless complicate the service of these railways so much as to induce many engineers to regard them as inapplicable to a great line upon which an active service is maintained. The reader who may desire to examine the various opinions upon the working of the Atmospheric system is referred to the elaborate report by the late Robert Stephenson upon the subject; in it he will see the objections faithfully recorded, and the various reasons by which that engineer was induced to recommend that it should not be adopted.

The Atmospheric system has been applied in some other cases, with no better success, to a method of producing the motion by a compression of the air, in a tube running along the railway and serving to retain the force there accumulated. This method is found in practice to be very defective; it is, in fact, far too complicated to be of easy application, and it is exposed to the greater part of the objections which have been urged against the system by means of exhaustion. The whole system of atmospheric traction is, however, now nearly abandoned; and the improvements in the locomotive render it less likely than ever to be adopted, although when its use was originally proposed it was believed that the conditions of heavy inclines were such as to justify its introduction.

Atmospheric Stones. [ÆROLITE.]

Atmospheric Tides. Diurnal oscillations of the atmosphere, produced by the attractions of the sun and moon, and similar to the tides of the ocean. This tidal action is so small that Laplace, after many experiments, thought its sensible existence doubtful. But in the *Philosophical Transactions* for 1847, Colonel Sabine gives an account of a series of observations of the barometer made at St. Helena, hourly, during a period of three years, which show an average excess of barometric pressure of '0014 parts of an inch at the hour when the moon is on the meridian (above or below the pole), and an average defect of '00115 when six hours distant from the meridian, making together an average difference of '00255 in. when the moon is on the meridian and when 90° from it. Observations reduced at Woolwich show the average difference to be '00365 in., or nearly four-thousandths of an inch. These differences are, no doubt, exceedingly minute; but as the observations were made with great care, and on being broken up into periods of six months were still found to give consistent results, it may be reasonably presumed that they represent with considerable accuracy the amount of the lunar influence on the atmosphere. The effect of the sun's attraction, being not only much smaller

ATRIUM

than that of the moon, but also masked in the diurnal barometric oscillation by the much greater and variable influence of the solar heat, probably cannot be satisfactorily determined.

Atoll or Lagoon Island. In Physical Geography, the name given to a particular kind of coral island. The Atoll consists of a chaplet or ring of coral, enclosing a lagoon or portion of the ocean in its centre. The average breadth of the part of the ring which rises above the surface of the sea is nearly a quarter of a mile, and it seldom rises higher than from six to ten or twelve feet above the surface. On the outer side the ring gradually shelves down to the distance of 100 or 200 yards from its edge, so that the sea deepens to about 25 fathoms, beyond which the sides plunge almost perpendicularly into the unfathomable depths of the ocean. On the lagoon side, where the water is calm, the bounding ring or reef shelves into it by a succession of ledges, also of living coral, but of a different species from those which build the exterior wall, and the foundation of the whole ring. The size varies from two to ninety miles in diameter. The lagoon islands are widely spread, but are found chiefly in the Pacific Ocean. Most frequently they occur in elongated archipelagos, extending in groups over a large surface; the Carolina Islands, for example, extend to 1,000 miles. Sometimes the lagoons have islands within them: Otaheite, the largest of the Society group, is a remarkable instance of this formation. The lagoon which encompasses it is thirty fathoms deep and hemmed in from the ocean by a coral band of the usual kind, at a distance varying from half a mile to three miles. (Somerville, *Physical Geography*.)

Atom (Gr. *ἄτομος*, from *ἀ* neg., and *τέμνω*, I cut). A part so small as not to be divisible.

Atomic Theory. In Chemistry. When substances combine chemically, they are found to unite in certain weights; thus, water is constituted of one part by weight of hydrogen and eight of oxygen, and the gases only combine in those proportions to form it. It is assumed that water is a compound of an atom of hydrogen and an atom of oxygen, and that the relative weight of the atom of hydrogen to the atom of oxygen is as 1 : 8; hence the atomic weight of water is 1 + 8, or = 9. The same theoretical views are applicable to all other simple and compound bodies, and the numbers which represent their combining weights are hence called their atomic or equivalent numbers. [EQUIVALENT; AFFINITY.]

Atomogynia (Gr. *ἄτομος*, uncut, and *γυνή*, a female). A word proposed to be substituted for angiospermia, the name of the second order of the sixth class of Linnæus, signifying that the ovary is not cleft into distinct parts.

Atonement. In Theology. [SACRIFICE.]

Atrium (Lat.). The name given by the Romans to the most important room in a dwelling-house. It was roofed over, with the exception of an opening in the centre called

compluvium, under which was a cistern in the floor to receive the rain-water discharged into it from the sloping roof above. The atrium has by many been identified with the *Cava adium*, while others have maintained that the former term signified only the covered part exclusive of the compluvium. Originally the only sitting-room and kitchen of the house, it became at length in the dwellings of the rich a reception-room, distinct from all the private apartments, adorned with marble columns and fitted up with great magnificence. (Smith's *Dictionary of Greek and Roman Antiquities*.)

The name was also applied to a class of public buildings which resembled the atrium of a private house, as the Atrium Publicum of the Capitol. (Livy xxiv. 10.)

Atropa (Gr. *ἀτροπῆς*, *inflexible*). The Solanaceous genus to which belongs the belladonna or deadly nightshade. This is an herbaceous perennial, bearing brownish-purple bell-shaped flowers, succeeded by berries which towards autumn become black and shining. All parts of this plant are highly poisonous. [BELLADONNA.]

Atrophy (Gr. *ἀτροφία*; à neg., and *τρέφω*, *I nourish*). A wasting away of the flesh.

Atropia (Gr. *ἀτροπός*). A poisonous alkaline substance, extracted from the *Atropa Belladonna*.

Atta. The name of a Fabrician genus of Hymenopterous insects belonging to the tribe (*Formicidæ*), characterised by their very minute palpi, and the large size of the heads of the neuter. Some of the largest species of ant, as the visiting ant of South America (*Formica cephalotes*; L.), are included in this genus.

Attachment. In law, a process issuing in a summary manner from a court of record against the person of any one guilty of a contempt of its rules. Attachment is most commonly granted against attorneys for malpractice, against sheriffs for making a false or no return to a writ, and against any parties neglecting to pay costs when ruled to do so.

ATTACHMENT, FOREIGN. Under the custom of the city of London, whenever process for debt from the mayor or sheriffs' court is returned nihil, the plaintiff may, upon its appearing that a third person is indebted to the defendant, obtain satisfaction of his claim by attaching the debt. This is called foreign attachment.

Attainder, Bill of. A species of extraordinary proceeding against parties accused of treasons or felonies which cannot be reached by the ordinary course of justice. During the reigns of the Tudors the more constitutional process of impeachment was entirely laid aside, and attainders were generally adopted in the case of state criminals. These bills usually commenced in the Lords. They have been very unusual in later times: the last recorded in Mr. Hatsell's *Precedents of Parliament* was directed against some persons concerned in the Scotch rebellion in 1746. Parliament is now

bound, in passing these acts, to adhere to the rules of evidence which are followed in ordinary courts of justice.

Attainder is the supposed stain or corruption of the blood of a criminal legally condemned, which, by the common law of England, immediately follows the pronouncing sentence of death. The attainder of a criminal follows upon judgment, and not upon conviction. Attainder is either on appearance (by confession or by verdict) or by process, otherwise termed by default or outlawry, in case of non-appearance. For the effect of attainder on the lands, &c. of the criminal, see *FORFEITURE*. It is enacted by 54 G. III. c. 145, that no attainder for felony, except in cases of high treason, petty treason, or murder, or abetting and counselling the same, shall extend to the prejudice of the rights of any persons except the offender during his life.

Attalea. A genus of lofty palms, one of the species of which, *A. funifera*, yields the Piassaba fibre, used in Brazil for ropemaking, and in this country for the manufacture of what are called bast-brooms. Another species yields the coquilla nut, much used in turnery.

Attar, Ottar, or Otto of Roses. The odoriferous oily principle of roses. [OTTAR.]

Attelabus (Gr. *ἀττελαβός*). The name of a Linnean genus of Coleopterous insects, characterised by moniliform antennæ, thicker towards the tip, and situated on the rostrum: the head pointed behind, and inclined. The species thus heterogeneously grouped together are now divided into the genera *Attelabus* proper, *Apoderus*, and *Rhynchites*. The latter includes some of the most beautiful weevils in this country, amongst which is the rare and splendid *Cereulia auratus*.

Attention (Lat. *attentio*). In Metaphysics, a steady exertion or application of the mind to any object of sense or intellect, in order thoroughly to understand and retain it. Attention is regarded by Stewart (*Inquiry into the Human Mind*, ch. 2) as a distinct faculty of the mind; and though this arrangement does not coincide with the views of many philosophers, his illustrations of the results or effects of attention are universally considered as a masterpiece of metaphysical disquisition.

Attenuants. Remedies which dilute the blood.

Attenuatus (Lat. *made thinner*). When the thickness of any part diminishes in some particular direction, it is often used in the sense of narrowed, or angustate.

Attic. In Architecture, a low story above an entablature, or above a cornice which marks the height of the main part of an elevation. The origin of the word is very doubtful. Professor Goldstickler refers it to the Sanskrit, *attaka*, a room on the top of a house. (*Transactions of the Philological Society*, 1851.)

Attic Base. In Architecture. [BASE.]

Atticism (Gr. *ἀττικισμός*). An elegant or concise form of expression. Milton, in his

ATTIRE

Apology for Smeetsynnaus, thus uses it: 'They made sport, and I laughed: they mispronounced, and I misliked; and, to make up the atticism, they were out, and I hissed.'

Attire. In Heraldry, the horns of stags, &c., used in emblazoning coats of arms.

Attorney (from the modern Latin *torno*, whence *attorno*, *attornatus*, signifying one who serves the *turn*, or is set in the place of another to do his business; and 'attornment,' signifying the assent of a tenant to the substitution of a new landlord on alienation of land). An attorney is either private or public. A private attorney is a person who acts for another in the conduct of his affairs out of court: for which purpose a verbal authority is in general sufficient, but for the performance of some acts, as, to deliver seisin of land, to transfer bank stock, or to execute a deed for another, he must be authorised by a formal power of attorney. He is not necessarily of the profession of the law; and the above, and all other the various matters unconnected with actual litigation in which he may be employed, such as the preparation of legal instruments, and the giving of advice and assistance in the transfer and management of property, may be undertaken by any other person. A public attorney, or an attorney at law, has been defined to be an officer of a court of record, legally qualified to prosecute and defend actions in courts of law on the retainer of clients. The circumstance of his being an officer of the court

which he may practise is important, as bringing him immediately within its summary jurisdiction, and thereby giving rise to his peculiar privileges and disabilities. A solicitor, in strict legal designation, differs from an attorney in practising in courts of equity instead of common law.

The power of suing and being sued by attorney was first given by statute in the time of Edward I. All persons may now appear in court by an attorney of their own appointment, except infants, who must appear by next friend or guardian; and married women, for whom, unless when proceeding in chancery in respect of their separate estate against their husbands, the attorney must be appointed by their husbands. Idiots, and persons charged with any criminal offence, must appear in person; lunatics, if of full age, and corporations, cannot appear otherwise than by attorney.

The admission and practice of attorneys are now chiefly regulated by the Act 23 & 24 Vict. c. 127 (1860) in connection with former acts. The first requisite to be complied with in order to become an attorney is to enter into a contract in writing, called articles of clerkship, on which a stamp duty is payable, with an attorney or solicitor actually practising, or other officer of court specified by statute, to serve him in the capacity of clerk for five years. No attorney or solicitor can take more than two articulated clerks at the same time, but some of the officers above referred to are allowed to take three. Persons who have taken the degree of B.A. or B.C.L. at Oxford, Cambridge or Dublin, within

ATTORNEY

a certain fixed period after matriculation at the university, and before execution of their articles, may be admitted as attorneys after a clerkship of three years. Clerks also who are bound for five years are allowed to reckon as part of their term a year passed as *bonâ fide* pupils to a barrister or special pleader. After expiration of service, and notice given of his intention to apply for admission, the clerk must go before a board of examiners established by the judges, and his fitness and capacity having been approved, be sworn in open court to demean himself honestly in his practice. His name is then entered on one of the records of the court, called the roll of attorneys, and he is duly admitted an attorney of that particular court. He may, however, when admitted of any one court at Westminster, practise in any one of the other courts there, in the name of an attorney of such other court, with his consent in writing. He may, at a trifling expense, be admitted a solicitor in any of the courts of equity, as a solicitor in equity may in like manner be admitted an attorney of any of the courts of common law. After admission he must pay a certain duty, and obtain his certificate. Should he for one whole year neglect to take out his certificate, he would, besides incurring a penalty for practising without one, be thenceforth incapable of acting in court in any professional character; but upon payment of all arrears of duty since the expiration of his last certificate, and of a further sum by way of penalty, he may be readmitted.

An attorney actually practising is supposed to be always present in court, and has for that reason many privileges in common with its other officers. He is accordingly exempted from serving on juries and inquests, and generally from filling all offices which require personal service; he has the privilege in all personal actions of suing in his own court. He is in general privileged from giving evidence of any confidential communication made to him by his client: this, however, is the privilege not of the profession but of the client, who may waive it if he please. An attorney cannot fill the office of justice of the peace, sheriff, and many other offices, and cannot be bail for another unless in criminal cases. He is not permitted to deal with his clients in the same unrestrained manner in which ordinary men may deal with each other; and when a purchaser of his client's property, is sometimes required to show affirmatively in the first instance that he has given for it its full value. To restrain him from extortionate and vexatious conduct, he is required, one month at least before bringing an action to recover fees for business done in court, to deliver to his client a bill of costs, which, upon application of the client and his undertaking to pay what shall appear due, will be taxed by an officer of the court, and if exorbitant be reduced to a fair and reasonable amount. Where an attorney has been guilty of gross ignorance, neglect, or misbehaviour, in the management

of his client's business, the court will interpose in a summary manner, and compel the attorney to pay the costs, or make a reparation for any loss occasioned by his default; and in cases of fraudulent malpractice grant an attachment against him, or even strike him off the roll. He is besides liable to an action for any gross and culpable negligence, by which the interests of his client may have been prejudiced. In matters of difficulty, not lying within his own department of the profession, he is protected from responsibility by acting on the opinion of counsel; but in matters of simple and ordinary practice, where the law will presume him to have the requisite knowledge himself, he cannot avoid his responsibility by consulting another.

Attorney-General. An officer made by letters patent. He is the public prosecutor on behalf of the crown, his duty being to exhibit informations in criminal matters which concern the crown, *ex officio*, or by virtue of his office. [INFORMATION.] He also files bills in the exchequer for any thing concerning the king's inheritance and profits, and bills are filed against him by others. The attorney-general has precedence of all other counsel. As chief legal adviser of the crown, in all matters falling within the purview of his office, his place is one of great importance, and is usually entrusted to new hands whenever an extensive change is made in the cabinet. It is generally understood that the attorney-general for the time being has an absolute claim to the office of the Chief Justice of the Common Pleas, if it fall vacant, besides having a claim (less weighty) on other high legal offices, if vacant.

Attraction (Lat. *attrahio*, from *ad*, to, and *traho*, I draw). A term used in physics to denote the tendency which we observe in certain bodies to approach one another, and to resist separation.

Attraction, with reference to the laws which it observes, may be divided into two kinds; one, taking place among bodies placed at measurable distances from each other; the other among the small particles of matter, where the effect is seen only at insensible or inappreciable distances. Among the instances of attraction, even at the greatest distances, the most remarkable is that of the attraction of gravitation, which belongs to all matter; which determines the motions and the figures of the planets and comets, and causes the descent of heavy bodies to the ground. For an account of the law which this species of attraction observes, and the astronomical phenomena which it produces, see GRAVITATION. The attraction of magnetism, of electricity, &c., are also instances of the action of bodies on each other at sensible distances. [ELECTRICITY; MAGNETISM.]

The second species of attraction exists only among the molecules or small particles of matter, and is hence called molecular attraction. The distances to which it extends are extremely small, or insensible. This species

of attraction is the cause of the coherence of solids; of crystallisation; the ascent of fluids in capillary tubes; the roundness of a drop of water; and of all chemical actions. [CAPILLARITY; COHESION; CHEMICAL AFFINITY.] The law of molecular attraction is not known; all that can be positively affirmed of it is, that it decreases in a much quicker ratio than the inverse square of the distance, and in many instances becomes prodigiously great, when the distance between the particles is diminished to its utmost limit.

Attraction, Calculus of. An important branch of applied Mathematics whose general object is the determination of the mutual action of bodies each of whose particles are supposed to attract (or repel) one another according to a known law. In all applications to the theories of Gravitation, the Earth's figure, Electricity, Magnetism, &c., this law is that of Newton, according to which the attraction between two material particles is a force whose direction coincides with the line joining the latter, and whose intensity is *directly* proportional to the *masses* of the particles, and *inversely* proportional to the square of their distance asunder. In the solution of the general problem of attraction, even when the attracted body is assumed to be a material point, great mathematical difficulties have to be overcome: the attempts that have been made, since Newton's time, to overcome these difficulties have contributed not a little to the perfection of mathematical methods. The history of the problem is not without interest; a sketch of it, with indications of other sources of information, will be found in a memoir by Charles, *Sur l'Attraction des Ellipsoïdes*, Paris, 1846.

The modern calculus of attraction may be said to be based upon the properties of a certain function of the coordinates x, y, z , of the attracted point, to which function Gauss, in his celebrated memoir entitled *Allgemeine Lehrsätze in Beziehung auf die im verkehrten Verhältnisse des Quadrats der Entfernung wirkenden Anziehungs- und Abstossungs-Kräfte*, gave the name *Potential*. This function is defined by the formula,

$$v = \int \frac{dm}{r},$$

where dm is the mass of the attracting element, and r its distance from the attracted particle; the integration being extended throughout the attracting mass.

Amongst the properties of the potential above referred to, the following two are the most important: *First*, the components of attraction in the directions of the co-ordinate axes are proportional to the first partial differ-

ential coefficients $\frac{dv}{dx}, \frac{dv}{dy}, \frac{dv}{dz}$.

Secondly, the sum $\frac{d^2v}{dx^2} + \frac{d^2v}{dy^2} + \frac{d^2v}{dz^2}$ of the second partial differential coefficients is equal to zero, when the attracted point is outside the attracting mass, and to $-4\pi g$ when it is within,

ATTRACTION, CHEMICAL

ρ being the density of the attracting mass immediately around the attracted point. Of these values 0 and $-4\pi\rho$, the first was given by Laplace, the second by Poisson.

The series of surfaces whose equations are obtained by putting v equal to a constant magnitude, have been called by Gauss and Charles *surfaces of equilibrium* (surfaces de niveau), the direction of the resultant attraction at any point being always normal to the surface of equilibrium which passes that point. In many questions, and particularly in the theory of electricity, these surfaces play an important part.

Amongst the authors to be consulted on the calculus of attractions the following may be mentioned:—Newton; Maclaurin; Simpson; Lagrange, *Memoirs of Berlin Academy*, 1774-5; Legendre, *Mémoires de l'Académie des Sciences*, 1783; Laplace, *Mécanique Céleste*; Ivory; Gauss; Poisson; Jacobi; Green, *Application of Mathematical Analysis to the Theories of Electricity and Magnetism*; Charles; Liouville; Cayley; W. Thomson, &c.

Attraction, Chemical. [AFFINITY.]

Attraction of Mountains. That power or force by which all the celestial motions are regulated, and to which we give the name of gravitation, does not act merely on the large masses of the universe; the smallest molecules of matter equally partake of its influence, and have an inherent and natural tendency to approach one another. This mutual action, in the case of small bodies, is insensible; because the attraction resulting from the whole mass of the earth absorbs, as it were, altogether, that which they exercise on one another, and renders their mutual approach infinitely small or imperceptible. But though the attractive force of matter is insensible in regard to small masses, it may become quite appreciable in the case of large mountains acting on the plummet of a delicate astronomical instrument. Newton himself was the first who deduced this consequence from his theory of universal gravitation. Some time elapsed, however, before any attempt was made to investigate the subject experimentally.

There are various ways by which the quantity of the attraction of a mountain may be ascertained. One of the most obvious is to take two stations, one on the south and the other on the north side of the mountain, and as nearly as possible in the same meridian. From the zenith distance of the same stars observed at each station, the difference of their apparent latitudes may be accurately determined. But the real difference of the latitudes can also be determined by a trigonometrical measurement on the ground of the distance between the same stations. The difference of these determinations gives the sum of the deviations of the plumbline on the opposite sides of the mountain; and when divided in the inverse ratio of the squares of the distances of the stations from the centre of gravity of the mass, will give the deflection of the plummet at each

ATTRACTION OF MOUNTAINS

station. But it is not absolutely necessary, indeed it may be impracticable, to make observations on the opposite sides of the mountain. Let the meridian altitudes of the same stars be observed first on north or south sides of it, and then at a station on the same parallel of latitude, but at such a distance from the mountain as to be out of the reach of its action. The difference of the altitudes in the two cases will show the amount of the attraction of the mountain.

The first attempt to ascertain the attraction of a mountain by actual observation was made by the French academicians, Bouguer, Godin, and Condamine, who, about the year 1738, were despatched to Peru for the purpose of measuring the length of an arc of the terrestrial meridian. Their experiments were made on the mountain Chimborazo, the highest of the Cordilleras, and the result seemed to show that the zenith point was altered by the attraction of the mountain to the extent of about $7\frac{1}{2}$ seconds of a degree. But this quantity was much too small to determine, with certain evidence, whether the mountain had or had not a sensible effect on the plumbline, for their instruments were not so perfect but that inconsistencies, amounting sometimes to upwards of 20 seconds, entered into their observations. From that time no further attempt was made to determine this interesting fact in physical astronomy, till the year 1774, when Dr. Maskelyne, the astronomer-royal at Greenwich, made an experiment of the same kind on the mountain Schehallien in Perthshire, with instruments capable of measuring the minute quantities in question. The difference of latitude of two stations on the north and south side of the mountain, compared with that which was inferred from the measurement of the distance on the ground, gave decidedly 5.8 seconds on each side, for the action of the mountain on the plummet of the zenith sector. The magnitude of the mountain was accurately measured at the same time, and with the data thus obtained a laborious calculation was made by Dr. Hutton, from which it resulted that the mean density of the earth is about five times that of water,

twice that of the ordinary rockstone near its surface. A third experiment of the same kind was made in 1810 by Baron Zach on the mountain Minet, at a little distance from the shore of the Mediterranean near Marseilles. The instrument which he employed for determining the latitudes, a repeating circle of 12 inches radius, was much less to be depended on for accurate results than the zenith sector of Dr. Maskelyne; but in other respects his operations, particularly those connected with the terrestrial measurements, appear to have been conducted with far greater science and practical skill. The result was, that the deviation of the plumbline from the true vertical, caused by the attraction of the mountain, reached two seconds of a degree. Baron Zach did not attempt the further researches required for comparing the density of the mountain with

ATTRIBUTE

that of the earth; such comparison, indeed, can only be made with respect to an insulated mountain, which *Mimet* is not.

Though the experiments hitherto made on this subject are few and imperfect, they are quite sufficient to establish the fact, that mountains are capable of producing sensible deflections of the plumbines of astronomical instruments. It is, therefore, of very great importance, in the measurement of degrees of the terrestrial meridian, to select for the station where the astronomical latitudes are observed places remote from large mountains, and where the local irregularities of the surface are not very considerable. After every precaution of this sort has been taken, some uncertainty will still remain, on account of local attraction; for it is obvious that a sudden and considerable variation of density in the strata under the surface will produce the same effect on the plumbine as a mass of matter elevated above it. To this cause is attributed, with much probability, a great part of the discrepancies between the results of operations made to determine the figure of the earth, and more particularly for ascertaining the variations of density by means of the pendulum. (See *Zach, Attraction des Montagnes*, Avignon, 1814; *Playfair, Works*, vol. iii.; *Hutton, Tracts*, vol. ii.; *Phil. Trans.* vol. lxxiii.; also *Bouguer, Figure de la Terre*.)

Attribute (Lat. *attributus*, part. of *attribuo*, *I assign*). In Logic, the same as Predicate. [PREDICATE; LOGIC.] Hence words expressing that which is affirmed or denied concerning something (such as adjectives) are called by some writers on grammar *attributives*.

Attributes. In the Fine Arts, certain symbols which are used to distinguish and characterise certain figures. Thus the eagle and thunderbolt are the attributes of Jupiter; the trident that of Neptune; the caduceus that of Mercury; the bow and quiver attend Love; the balance and sword accompany Justice, &c. &c. Nearly all the various saints have their distinctive attributes. (See *Husenbeth, Emblems of Saints*, &c. 1850.)

Attwood's Machine. A pulley, the pivots of which rest on wheels to diminish friction in rotation. It is used in demonstration of the laws of uniformly accelerated motion. [GRAVITATION.]

Aubaine, Droit d'. In French Jurisprudence, the right of the sovereign to the succession of a foreigner not naturalised, or of a naturalised foreigner dying intestate without heirs resident within the realm. The word is derived from the old French *aubain*, *foreigner*, said to come from the Latin *alibi natus, born elsewhere*. The *droit d'aubaine* still exists in various countries; and, although abolished at the Revolution, was restored by the Code Civil of Napoleon.

Auchenia (Gr. *αὐχὴν, the neck*). In Mammalogy, this term is restricted to the region of the neck, below the nucha or nape. Also, the name of a genus of *Camelidae*, comprising the

AUGSBURG, CONFESSION OF

llama, guanaco, vicuna, and alpaca, in which this region of the neck is remarkably elongated.

Auditor (Lat.). One who examines and verifies the accounts of officers and others entrusted with money. The term is derived from the Latin *audio, I hear*: probably from the ancient practice of delivering accounts *viva voce*. Receivers-general of fee-farm rents, &c. are termed auditors. Officers with the same title are assigned by courts of law to settle accounts in actions of account, &c. The auditors of the exchequer were officers appointed to take the accounts of receivers of public revenues. The present board of commissioners for auditing the public accounts, exercising the duties formerly divided between various officers of the exchequer, was constituted in the year 1806. In Germany the junior legal functionaries are termed auditors. Its most usual sense seems to have been originally given to the word in France, where the members of the *Chambres des Comptes* were divided into *conseillers-maitres* and *conseillers-auditeurs*.

Auerbachite. A silicate of zirconia, of a brownish-grey colour; named after Dr. Auerbach. It is nearly allied to Zircon in form and composition, but differs from it in inferior hardness and specific gravity. Probably it is altered Zircon in which a portion of the zirconia is removed.

Auger (A.-Sax. *nafgar*). A carpenter's boring-tool for piercing the holes to be traversed by large bolts, or treenails. It is made with an end able gradually to force an entrance, and is curvilinear in plan, to allow the tool to clear itself as it pierces through the wood; the sides are made slightly concave, towards the direction of the axis of the tool. The term Auger is also applied to an instrument for determining the quality of soils, the nature of the rocks or strata upon which they lie, and the presence of springs of water.

Augite (Gr. *αὐγὴ, splendour*). A crystalline mineral common in volcanic and basaltic rocks. It is the *pyroxene* of Haüy.

Augmentation, Arms of. In Heraldry, coats given by sovereigns to subjects as a mark of honour, to be quartered with their own; or charges, such as ordinances charged with some device, to be borne in their family shield. Such coats or devices are in general either significant, i. e. bearing some relation to the nature of the achievement for which the honour is bestowed; or they are portions of the royal arms.

Augmentation of Stipends. In the church of Scotland the stipends of ministers are under the control of the Court of Session. That court has the power to entertain applications for augmentation from clergymen, and either to grant or dismiss them. But twenty years must elapse before such application can be renewed.

Augsburg, Confession of. A formulary drawn up by Luther and Melancthon, and presented to Charles V. at the diet held at Augsburg in 1530. It is adopted by the Lutheran church, but did not at the time succeed in comprehending all the reformers, and

was the occasion of a separation between the followers of Luther and the party who called themselves the Evangelical Reformed Church, which has continued ever since.

Augurs (Lat. *augur*). Roman soothsayers, who professed to foretell events by the flying, singing, or feeding of birds. Their office was one of great importance in the state, as no enterprises or ceremonies were performed unless they declared the omens favourable. Accordingly the members of their college were always elected from the most honourable citizens. Their divinations were called auguries or auspices, between which there is sometimes a distinction made; the latter meaning such as were derived from the inspection of birds, the former being extended to all omens or prodigies whatever. The Romans derived their knowledge of augury from the Etruscans, who were celebrated for their skill in this and other religious ceremonies. [OMENS; SINISTRA.]

August. The eighth month of the year. The ancient Roman year commenced with March, and the sixth month was called Sextilis. The name was changed to August in compliment of Augustus Cæsar. In the calendar of Julius Cæsar the distribution of the days through the several months was more commodious than the present arrangement. The first, third, fifth, seventh, ninth, and eleventh months consisted of thirty-one days each, and the other months of thirty, excepting February, which in common years contained twenty-nine days, but in leap years thirty. In order to gratify the frivolous vanity of Augustus, who thought it a disparagement that the month bearing his name should contain fewer days than July, which was named after the first Cæsar, a day was taken from February and given to August. Such was the origin of the capricious distribution of the days among the different months which now prevails over the whole Christian world; and which, being founded on no principle, requires some pains to be remembered.

Augustales. The epithet given to the priests or flamens of Augustus Cæsar. [FLAMEN.]

Augustan Age. A term used to designate the reign of Octavius, more commonly known as Augustus Cæsar, the most brilliant period in the literary history of Rome. Among the poets who then flourished, the greatest were Virgil, Horace, Propertius, Ovid and Tibullus. But it was not merely for ornamental literature that the age in question was distinguished. The science of jurisprudence, the only original intellectual possession of great value to which the Romans can lay undisputed claim, then received its full development: the immense masses of Roman statutes were perspicuously arranged; and the boundaries of strict law on the one hand, and equity on the other, were respectively ascertained. In this age, too, the wealth of Rome, as the seat of a vast empire, was greatly increased; and so numerous and splendid were the buildings with which

it was embellished, that they justified the saying of Augustus—that he found Rome of brick, and left it of marble.

Augustan History. A series of histories of the Roman empire from the year 167 A.D. to 285 A.D., ascribed to the following six authors: Delius Spartianus, Julius Capitolinus, Æl. Lampridius, Vulcatius Gallicanus, Trebellius Pollio, and Flavius Vopiscus.

Augustine. In Ecclesiastical History, an order of monks and nuns established in the eleventh century, apparently in commemoration of the monastic societies assembled by Saint Augustine in the fourth, but which had long ceased to exist. [ORDERS, ECCLESIASTICAL.]

Augustinians. In Ecclesiastical History, divines who held, on the supposed authority of Saint Augustine, that grace is effectual, from its nature, absolutely and morally, and not relatively and gradually.

A sect of the sixteenth century, under this name, maintained that the gates of heaven will not be opened till the general resurrection.

Aula Regia (Lat. *King's Hall*). In English Law, a Court established by William the Conqueror, and regulated by Magna Charta: which may be said to have merged in that of King's Bench. (*Steph. Black. bk. v. ch. iv.*)

Aulic Council or **Reichshofrath**. A council of high powers and dignity in the German empire. The Aulic Council and Imperial Chamber (*reichskammergericht*) were the two supreme courts in that empire. The former consisted of a president, vice-president, and eighteen councillors, six of whom were Protestants, with the peculiar privilege that, if unanimous, their votes could not be overruled by those of the Catholics. This court had exclusive jurisdiction in various affairs, principally those which concerned the imperial government.

Aulostoma (Gr. *αὐλός*, a pipe; *στόμα*, a mouth). A genus of Acanthopterygians belonging to the family called by Cuvier *Bouchers en flute*; including the pipe-fishes, or those species which are characterised by a mouth which is lengthened into a kind of tube or pipe.

Aura (Lat. *air*). In Botany, the subtle essence which is contained within the grains of pollen, and in which is supposed to reside the power of fertilising the ovules. It is now generally considered that this essence is imaginary, and that fertilisation is produced by the descent of minute organic particles through the stigma to the ovules.

AURA. A sensation resembling a wind, or the being breathed upon. *Aura epileptica* is a sensation often experienced by epileptic patients, resembling the ascent of a blast of cold air from the extremities upwards.

Aurantiaceæ. A considerable natural order of Exogens, with polypetalous flowers, confined to the warmer parts of Asia, or the nearest parts of Africa. They have dotted cavities filled with a fragrant oil; and succulent edible fruit, covered by an aromatic skin. The orange, the shaddock, the lime, the lemon, are all species of the genus *Citrus*, and the best

known in Europe. In the woods of India there are some species that climb; and in the Himalayas, China, and Japan exist species of *Skimmia* which are found to be hardy evergreens in this country.

Aurantia. A neutral crystalline principle obtained from the spongy part of the peel of lemons and oranges.

Aurates. Crystalline compounds of auric acid, or peroxide of gold.

Aurelia. In Entomology, the name given to the nymph, or quiescent state of transformation of an insect, on account of the metallic golden lustre which is reflected from the case of the nymphs of some diurnal Lepidoptera.

Aureola, Aureole (Lat. aureolus, *golden*). In Painting, the golden glory with which painters decorate the heads of the saints, martyrs, and confessors. There are various kinds of glories: the circle or *Nimbus*, which, when it encloses a cross, belongs to Christ alone; when without it, indicates canonised saints; and the radiation of gold lines, which is given to persons whose lives have been considered worthy of imitation, and are called *Beati* or *Blessed*, but who have not been canonised by the church. There is also the *Vesica*, or almond-shaped aureole, called by the Italians *Mandorla*; it is given to the Lord, or the Virgin Mary holding the infant Christ: it surrounds the entire figure. It is called *Vesica* from its resemblance to a bladder, and was originally derived from the form of a fish, used by the early Christians to symbolise the Lord, from the Greek word *ἰχθῦς* (*ichthus*), containing the initials of the following sentence—*Ἰησοῦς Χριστὸς Θεοῦ Υἱὸς Ὁρθόδοξος*—Jesus Christ, the Son of God, the Saviour.

Aureus. A Roman gold coin worth a little more than sixteen shillings, according to the proportion given by Tacitus. But it varied, as appears from the different values assigned to it, from 1*l.* 4*s.* to 12*s.* Its weight was about 2½ oz. avoirdupois.

Auric Acid (Lat. aurum, *gold*). A term frequently applied by chemists to the *peroxide of gold*.

Aurichalcite (Lat. aurum, *gold*, and Gr. χαλκός, *copper*). A carbonate of zinc and copper occurring in acicular crystals. It is found in small groups of a pale-green or blue colour at the Rutland Mine, near Matlock in Derbyshire; at Roughton Gill in Cumberland; also at Loktetskoi in the Ural and at Retzbanya in Hungary.

Auricle (Lat. auricula, *a little ear*). Signifies in Mammalogy, the external ears, which are said to be 'marginate' (*auricula marginate*) when bordered by a helix, or involute margin; — to be 'operculate' (*auricula operculata*) when provided with a largely developed tragus, which stands out like a subsidiary auricle; — to be 'concealed' (*auricula abscondita*) when covered by the hair. In Ornithology, the circle of feathers surrounding the entry to the ear-passage are called auriculars. In Anatomy, the venous chambers of the heart are termed auricles.

Auricula (Lat.). A genus of terrestrial Pulmoniferous Gasteropoda, in which the shell is oblong, with thick dark epidermis; spire obtuse; aperture long, narrow, rounded in front, with two or three strong folds on the inner lip; outer lip expanded and thickened. They frequent salt marshes, damp hollows, and places overflowed by the sea; they were long regarded as marine animals, and their shells confused with those of *Tornatella* and *Ringicula*. (Woodward, *Man. Mollusca*.)

Auricular Confession. In Theology, confession of sins to a priest in private, distinguished from the public confession which was enjoined as a duty by the primitive church but was early allowed to drop into disuse. It was on occasion of the scandal which the original practice produced, that Leo the Great, in the fifth century, first recommended private confession to a priest in certain cases. It was not till the fourth council of Lateran in 1215, that the doctrine of the necessity of this practice was formally established.

Auriculate (Lat. auricula). When the base of a leaf or similar part projects on each side of the axis in the form of a little round lobe.

Auriflamme. [ORIFLAMME.]

Auriga (Lat. *the charioteer*), one of the ancient northern constellations situated between Perseus and Gemini. It contains the star Capella of the first magnitude.

Auripigmentum (Lat. from aurum, *gold*, and pigmentum, *paint*). Yellow sulphide of Arsenic. [ORPIMENT.]

Aurocyanides. Compounds of the cyanide of gold with basic oxides. The aurocyanide of potassium is used in the art of electro-gilding.

Aurohydrocyanic Acid. A combination of cyanide of gold with hydrocyanic acid.

Aurora (Lat.). In Mythology, the goddess of the morning. She is the same as the Greek goddess Eos, the daughter of Hyperion and Euryphassa. The legends about Eos are as varied as those which relate to Apollo. In the beautiful myth of Cephalus, she is the rival of Procris, who represents the morning dew. Another legend spoke of her as the wife of Tithonus, son of Laomedon, king of Troy: for whom, when she asked and obtained immortality, she forgot to ask perpetual youth. It is from his couch that Virgil speaks of her as rising to bring back light after the hours of darkness. In Homer she is also the mother of Memnon, at whose death she is said to weep tears of morning dew.

In the *Odyssey* (v. 390, x. 144) Eos is represented not only as going before Helios (the sun) at his rising, but as reappearing at the close of day, which is said to be ended by her. In addition to her loves with Tithonus and Cephalus [Παυκός], she is said to have carried Cleitus to the home of the inner gods, and to have lured to Delos [Δελος] the hunter Orion, whom Artemis slew with one of her arrows. [MYRMIDONS.]

AURORA BOREALIS

Aurora Borealis (Lat.). *Northern lights*, *Polar lights*, or *Streamers*. An electrical phenomenon generally appearing in the northern part of the sky, and presenting a light somewhat resembling the dawn or break of day. The appearances which it exhibits, and the forms it assumes, are so proverbially unsteady, that it is not possible to comprehend them under any general description. Most frequently the phenomenon appears to proceed from a sort of horizontal cloud or haze in the northern part of the sky, rising a few degrees above the horizon, and stretching from the north towards the east and west, so as to form an arc, which in some instances has been observed to extend upwards of 100°. The upper edge of the cloud is whitish and luminous, the lower part often dark or thick, and sometimes the clear sky may be seen between it and the horizon. From the upper part of the cloud streams of light shoot up in columnar forms, reaching sometimes only a few degrees, sometimes to the zenith, or even beyond it. Instances occur in which the whole hemisphere is covered with coruscations; but the brilliancy is greatest, and the light strongest, in the north near the main body of the meteor. The streamers have in general a tremulous motion, and, when close together, present the appearance of waves or sheets of light following each other in rapid succession. When several columns, issuing from different points, meet at the zenith, a small meteor is formed of greater brilliancy than the separate columns. The phenomenon sometimes continues a few hours, occasionally the whole night, and even for several nights in succession. It generally commences at most two or three hours after sunset, and very rarely in the morning or much after midnight. Auroras have been observed even before the evening twilight has disappeared. In the Shetland Islands, and other countries in high latitudes, the northern lights are the constant attendants of clear and frosty evenings in winter. They are most frequent in

Although the aurora borealis is most frequently seen in the northern hemisphere, yet several observers have witnessed it in high southern latitudes.

This phenomenon is due to electric discharges passing through highly rarefied air in the upper regions of the atmosphere; a similar appearance may, in fact, be artificially produced by causing electric sparks to pass through a glass vessel containing rarefied air.

Aurora-red. The term applied in Mineralogy to minerals of a red colour mixed with much yellow; as in some kinds of Realgar.

Aurotellurite. A variety of Sylvanite from Nagyag in Transylvania, where it occurs disseminated and crystallised in small four-sided prisms of a silver-white colour inclining to brass-yellow and sometimes to grey.

Aurum Musivum. An obsolete chemical name of the artificial bisulphide of tin, commonly known as *Mosaic gold*.

AUSTRALIA

Auscultation (Lat. *auscultatio*). A method of distinguishing healthy and diseased states of the body by the study of the sounds produced by the movements of the different organs. These sounds differ more or less when the parts are diseased from those which belong to their healthy functions. [*STETHOSCOPE*.]

Auspices. [*AVURS*.]

Australia. This important tract of land—the smallest of the continents but very much larger than all the islands of the earth together—is the principal detached land of the southern hemisphere. It measures about 2,800 miles from east to west, and 2,000 miles from north to south, and has an area of nearly 4,000,000 of square miles. The whole of the west and the greater part of the south coasts are almost without indentation. The east coast is also little broken. The north and the south-easterly coasts are broken by some large and important bays.

Australia is crossed by the Tropic of Capricorn, which divides it into two unequal parts. It is thus partly tropical and partly temperate, but owing to the form of the land the climate of the interior is singularly dry, and is subject to long summer droughts. There are in its compact mass few well-marked lofty mountain chains, and few navigable rivers of importance discharging their waters into the sea. There are no important lakes, though very large pools of water are collected at intervals in the wet season. In some respects Australia resembles Africa, especially in the absence of a great central mountain range influencing the drainage. It is, however, less adapted to be the residence of large quadrupeds, and has a less luxuriant vegetation, though, perhaps, its climate is on the whole better fitted to the habits and wants of tribes of men accustomed to active exertion and the modern forms of civilisation.

Wanting the commanding natural features which characterise Europe, Asia, and the two Americas, and which are even present in Northern Africa, Australia, though long since peopled to some extent from England, has remained till lately an unknown country. It has now been everywhere coasted, and has been surveyed to some distance in the interior—it has been entered from the east and south across the mountains and to the rivers, and most of the rivers have been followed for some distance into the interior. Very recently it has been crossed completely, and all doubt as to the condition of the interior is set at rest. There can be no further difficulty in understanding its geographical and physical condition, though much more time will elapse before its interior is rendered available.

A large part of Central Australia consists of a low table land, imperfectly watered, covered only at intervals with vegetation, and barren and dry during some months of the year. Partial deserts interreno between tracts of large size susceptible of cultivation, and there is every probability that as man advances, and

AUTHENTIC

encourages vegetation, the climate will improve, and the drought become less trying.

The best districts of Australia as at present known are the fringes of land on the south, south-east, east, and northern parts of the land, and the banks of the rivers derived from the western flanks of the eastern mountain chain narrow strips on the west coast are also regarded as capable of cultivation, but they hardly seem to lead into the interior.

Mountain systems.—About a hundred miles from the east coast, but approaching the coast towards the north, and receding from it towards the south, is the important chain of the Blue Mountains or Australian Alps, whose height generally varies from 2,500 to 4,700 feet above the sea, though a few isolated peaks rise to nearly 7,000 feet. This is the principal and almost the only mountain chain of any kind in the whole land. Numerous spurs proceed from it.

River systems.—The only important river systems of Australia are those connected with the western flanks of the principal mountain chains. These drain the whole of that comparatively small portion of the continent. The Murray and its tributaries—the principal being the Darling river—belong to the colonies of South Australia and Victoria, and give great value to these colonies. The chief gold districts of Australia are in the country which the waters flowing into this river traverse. Small rivers empty themselves into the ocean on the north coast, and in the Gulf of Carpentaria, but they are not navigable more than a short distance into the interior. The west and south-west coasts are singularly unbroken. For a long distance no stream whatever seems to enter the ocean, while the small rivers known on the west coast do not penetrate beyond the low hills of the coast range.

Authentic, Authenticated (Gr. *authentikos*). In Diplomats, ancient MSS. were formerly termed authentica when originals, in opposition to copies. In the modern acceptance of the word, it is only applied to instruments bearing marks of having been executed by the proper authority.

Authentic Melodies. In Music, such as have their principal notes contained between the key-note and its octave. This term is applied to four of the ancient church modes or tones in music which rise a fourth above their dominants, which are always fifths above their finals, that is, rise to complete their octaves, thus distinguished from plagal melodies, which fall a fourth below their finals.

Autobiography. This word is made up of three Greek words, and signifies literally the life of a person written by himself. Such memoirs may be divided into two classes: those in which the chief object of the writer is to illustrate the history of his own mind and heart, and the manner in which these were swayed by the destinies of his life; and those in which his purpose is merely to give a sketch of the scenes

AUTOMATIC

and events which have occurred within his own experience, and of characters with which he has been brought in contact. To the first class of writings belong the Confessions of Saint Augustine, whence Rousseau borrowed the title of his own 'Confessions.' In the more strictly narrative class, Julius Caesar, Napoleon, Cardinal de Retz, Frederick the Great, are among the great men who have left us in greater or less detail the narratives of their achievements.

Autocarpious (Gr. *abros*, and *kapros*, fruit). A name given to such fruit as consists of nothing but pericarp, without any additional organ, such as a calyx, adhering to the outside.

Autocthonous (Gr. *abrotythones*). The Greek term for the aboriginal inhabitants of a country, implying that they were sprung from the soil. The Athenians, whose territory, as they maintained, had been held by the same race from time immemorial, chiefly on account of its sterility which offered no incitement to foreign aggression, particularly laid claim to this title, in memorial of which they wore the emblematic grasshopper as part of their head-dress. [ABORIGINES.]

Autocrat (Gr. *abrokrator*). A title given to Athenian generals when invested with full command by the republic. In modern political phraseology, the term autocrat, signifying a sovereign possessed of absolute power, is usually confined to the emperor of Russia.

Auto-da-Fé (Port. *act of faith*; Ital. *atto di fede*). A public solemnity held by the Court of the Inquisition in Spain and Portugal. It was a gaol delivery, at which extracts from the trials of offenders, and the sentences pronounced by the judges, were read; after which, absolution was conferred on those who were penitent and discharged. Those who were condemned to death (*relajados*) were then transferred to the secular authority: and here the auto, properly so called, ended; the execution of the victims taking place immediately afterwards, under the authority of the civil judge, secretary to the Inquisition attending. The ceremonial of the autos, processions, horrible executions, &c. are amply described by many writers. See especially Llorente's *History of the Inquisition*; *A Relation of the Inquisition in Portugal*, published by Bishop Burnet; and Olmo's *Account of the General Auto-da-Fé at Madrid* in 1680. Autos were of several sorts: the public general act (*auto publico general*), to which the above descriptions apply; the particular act, at which only the officials of the Inquisition were present; *antillo*, or little act; and *auto singular*, the condemnation of a single individual. [INQUISITION.]

Automatic (Gr. *autoματος*, self-acting). In Physiology, a term applied to those muscular actions which are not dependent on the will or other act of the mind: such are the successive contractions of the hollow viscera of organic life, e.g. the heart, the intestines, the ureters, urinary bladder, the uterus; the involuntary movements of respiration; the motions of the muscles

AUTOMATON

of the eye during sleep; the persistent contraction of the sphincters. [REFLEX; MOTORY.]

Automaton (Gr. *self-acting*). A name applied to pieces of mechanism so constructed as to imitate the actions of living animals. The term Android (from the Gr. *anthrōp, man*) is sometimes applied to such machines as resemble the figures and imitate the actions of mankind.

The extent to which these useless but ingenious contrivances have been sometimes carried is very surprising. The following are a few of the best authenticated instances:—The flute-player of Vaucanson, described by D'Alembert in the *Encyclopédie Méthodique*, was exhibited in Paris in 1738. It played on the flute exactly in the same manner as a living performer, and commanded three octaves, the fullest scale of the instrument. Its height was nearly six feet. In Hutton's *Mathematical Recreations*, a description is given of an automaton group, constructed by M. Camus for the amusement of Louis XIV., consisting of a coach and horses, with coachman and page, and lady inside, &c., by which the action of driving up, alighting, presenting a petition to the king, and setting off again, were mimicked with wonderful accuracy. In 1741, Vaucanson produced a flageolet-player, which played the flageolet with the left hand, while it beat a tambourine with the right. He also produced a duck, which dabbled in the water, swam, drank, and quacked like a real duck; raised and moved its wings, dressed its feathers with its bill, took barley from the hand and swallowed it. (Montucla, *Hist. of Math.* iii. 802.)

Automaton flute-players have likewise been exhibited in this country, of the size of real life, which performed ten or twelve ducts. Maelzel, the inventor of the metronome, exhibited an automaton trumpeter at Vienna, of which a description is given in the *Journal des Modes* for 1809. It was a martial figure, in the uniform of a trumpeter of an Austrian dragoon regiment, which played the Austrian and French cavalry marches, and all the signals of those armies. (*Dict. of Musicians*, London 1827.) For other instances of automata, see *Penny Cyclop.*; Hutton, *Math. Dict.*; *Enc. Brit.* art. 'Androides.'

Automolite (Gr. *αὐτομολος, a deserter*). A crystalline mineral consisting chiefly of alumina and oxide of zinc. It is the Zinc-spinelle of some authors. The name has reference to the presence of oxide of zinc in a mineral not resembling a metallic ore.

Autopsy (Gr. *αὐτοψία*). Ocular evidence.

Autotypography. [PRINTING.]

Autumn (Lat. *autumnus*). The third of the four seasons of the year. In a popular sense it denotes that period of the year in which the fruits of the earth are gathered in. Astronomically speaking, it is the time during which the sun is passing from the autumnal equinox to the winter solstice. Owing to the elliptic form of the earth's orbit, the seasons are not all of the same length; and owing to the precession of

AVENA

the equinoxes, their lengths vary a little from age to age. In the present century, the time which elapses between the sun's passage through the autumnal equinox and his reaching the winter solstice, or while he passes through the three signs of Libra, Scorpio, and Sagittarius, is 89 days 16 hours and 47 minutes. The autumn of the northern hemisphere corresponds to the spring of the southern.

Autumnal Equinox. The day on which the sun passes through the equator, going southward, or on which his declination changes from north to south. When the sun is in the equator, the day is equal in length to the night all over the world. [EQUINOX.] The autumnal equinox falls generally on the 22nd or 23rd of September.

Autumnal Point. One of the two points in which the ecliptic intersects the equator. It is the same as the first point of the sign Libra.

Autunite. A mineralogical synonym for the Uranite of Autun in France. It has also been found in Cornwall.

Auxiliary Verbs. In Grammar, those which are said to 'aid' the sense of other verbs; as 'to have,' 'to be.' The peculiarity of the classical, as distinguished from the principal modern European languages, consists in the absence (in the former) of these verbs, the place of which is supplied by inflexion of the original verb.

Avalanches (Fr.). Masses of snow which collect upon the heights of mountains, and rapidly sliding down their sides acquire enormous bulk by fresh accumulations; when they ultimately reach the valleys below, they often cause great destruction.

Avanturine or Aventurine. A variety of rock-crystal, having a spangled appearance generally caused by scales of Mica, but sometimes by minute octahedral crystals of copper. The name is borrowed from that of the artificial gold-spangled glass, made in imitation of the natural stone. This glass having been produced in the first instance by the accidental (*par aventure*) dropping of some brass filings into a pot of melted glass, was called *Aventurine*: subsequently the name was applied to the stone of which the glass was an imitation. It is found in Spain, Siberia, India, &c.

Avast. A sea term, signifying enough; stop; cease.

Avatar (Sansk. *a descent*). In Hindoo Theology, the descent on earth, or incarnation, of a divinity for some special purpose. The ten incarnations or avatars of Vishnú are among the most celebrated instances.

Avellana (Abella or Avella, *a town of Campania, celebrated for its fine filberts*). One of the names of the common hazel nut. The Spaniards in Chili apply the name to the fruit of *Quadria heterophylla*, from its resemblance to filberts.

Avena (Lat.). A genus of corn-bearing grasses, one of which, *A. sativa*, is the common Oat, a tall annual, characterised by a loose com-

AVENTURINE FELSPAR

pound equal panicle, and two-flowered spikelets. The Oat is extensively cultivated in most of the northern countries of Europe as a bread corn. It has long occupied the same place in Scotland that rye occupies in Germany and the potato in Ireland. In England it is chiefly used for feeding horses; but it is also used to a considerable extent as food for man, particularly in the northern counties. The varieties of the common Oat cultivated in England may be arranged according to their colour—black, grey, dun-brown or red and white. The first two classes, being comparatively hardy, may be raised on inferior soils, and in situations unsuitable for the white. The only black oat now cultivated to any extent in England is the black Tartarian; but many kinds are still raised to a considerable extent in some parts of Scotland, and the Western Islands. The dun or red oat is principally confined to the uplands of Scotland, and some of the northern and midland counties. White oats are, speaking generally, less hardy than either of the other varieties, and require a better soil; but they are also earlier, heavier, and yield a greater quantity of meal. There are numberless, and some widely different, sub-varieties of the white oat. The white Poland oat is the earliest, and the white Canadian the heaviest, of them. That which is called the potato oat has long enjoyed the highest reputation in this country, as a productive sort of good quality. The produce of oats varies very greatly. When the ground is foul or exhausted, not more than 20 bushels an acre may be obtained; but in a rich soil well managed and in favourable years, 60, 80, and sometimes even 100 bushels have been reaped, weighing from 35 lbs. to 48 lbs. a bushel. The price of oats amounted at an average of the 27 years ending with the 31st December 1863, to 23s. 2d. Imp. quarter.

Aventurine Felspar. [Sunstone.]

Avenue (Fr., from Lat. *ad, to*, and *venio, I come*). In Landscape Gardening, is a road forming the main approach to a house; the term is also applied to any broad walk of grass or gravel, bordered on each side by trees or statues or vases recurring at regular intervals. When the modern style of gardening began to take the place of the ancient style, the term avenue gave way to that of approach road, which subsequently became shortened into that of approach.

Average (Ger. *haferei, sea-damage*). In practical Arithmetic is a quantity intermediate between several other quantities, and the sum of the latter is equal to the sum of the same number of magnitudes each equal to the average. See **ARITHMETIC MEAN**, with which term average is synonymous. It is a common error to suppose that the average of a number of averages is equal to the average of the original quantities.

Average, General. In Mercantile Law, whatever damage or loss is incurred by any part of the ship or cargo for the preservation

AVES

of the rest. When such damage accrues, the several persons interested in the ship, freight, and cargo, contribute their respective proportions to indemnify the owner of the part in question against the damage or necessary expense which has been incurred for the good of all. General average, therefore, cannot be unless the whole adventure has been in jeopardy. Every species of loss incurred on any part of the cargo in the course of the voyage, is somewhat loosely denominated average, or particular average. [INSURANCE.]

Avernus (Lat.; Gr. *Ἄφρος*, from *ἀ* neg, and *ἔφρῳ*, a bird, as being a place over which, owing to its exhalations, no bird could fly). A lake in Italy ten miles west of Naples, celebrated as the entrance to the infernal regions. Virgil speaks of the Cumæan Sibyl as inhabiting a cave adjoining this lake (*Æneid*, vi. 237-242), which Augustus connected with the Lucrine lake, to form by the junction of both the great Portus Julius. This lake still exists under the name Lago d'Averno; it is about a mile and a half in circumference, and in many places 190 feet deep. Avernî is a generic name for certain lakes or other places that infect the atmosphere with pestilential vapours.

Averrhoa. A genus of arborescent Indian *Osolidaceæ*, named after Averrhoes, a celebrated Spanish physician. *A. Bilimbi*, the Blimbing, and *A. Carambola*, the Carambola, produce fruit which is used in India in preserves and pickles.

Averruncator (Lat. *averrunco, I avert*). In Arboriculture, is an instrument for cutting off the branches of trees, consisting of two blades secured to the end of a rod, one having a movable joint, and by means of a line fixed to it operating like a pair of scissors. In the improved forms of this instrument, the point on which the moving or cutting blade turns, instead of being confined to a circular opening, works in a longitudinal one; in consequence of which, instead of a crushing cut, like that produced by common hedge shears, a draw cut is formed, which leaves the section from which the branch or shoot has been amputated as clean as that produced by a pruning knife.

Averse (Lat. *aversus, turned back*). In Ornithology, when the posterior extremities are attached to the trunk near the anus, so that the body is supported erect, as in the penguin, they are termed '*pedes aversi*.'

Aves (Lat.). The name of a class of warm-blooded vertebrate animals, characterised by a double circulation and respiration, oviparous generation, a covering of feathers, and by their anterior extremities being organised for flight. The posterior extremities present five principal modifications, affording characters which distinguish five primary orders. In the first order the foot (fig. a) has three toes before and one behind, all armed with long, strong, crooked, and more or less retractile talons, adapted to seize and lacerate

AVES

a living prey; this structure is associated with a strong, curved, sharp-edged and sharp-pointed beak, often armed with a lateral tooth; a very muscular body, and capability of rapid and long-continued flight. This order is termed *Raptores* or *Accipitres*. The second type of foot presents three toes before and one behind, and placed on the same level; slender, flexible, of moderate length, and provided with long, pointed, and slightly curved claws. The two external toes are united by a very short membrane. A foot so constructed (fig. *b*) is especially adapted for the delicate operations of nest-building, and for grasping and perching among the slender branches of trees; hence the order so characterised has been termed *Insessores*, and, from including the smaller tribes of birds, *Passeres*. In the third type of foot (fig. *c*) the hinder toe is raised above the level of the three anterior ones; this lessens the power of perching; but the other toes are strong, straight, and terminated by robust obtuse claws, adapted for scratching up the soil, and for running along the ground; the legs are for this purpose very

strong and muscular, and the order so characterised is termed *Rasores*, or *Gallinæ*. The modification by which birds are enabled to wade and seek their food in water along the margins of rivers, lakes, and estuaries, is gained simply by elongating the bones of the leg (tibia and metatarsus), which are covered with a naked scaly skin. The three anterior toes are very long and slender, as in the Parra Jacana, by which the bird can support itself upon the broad floating leaves of aquatic plants; sometimes they are of moderate length. The hind toe is elevated, short, and sometimes wanting (fig. *d*). The order of birds characterised by this form of leg and foot is termed *Grallatores*, from the resemblance of the posterior extremities to stilts. In the last form of foot (fig. *e*)

AVICULA

the toes are united by intervening webs; the legs are placed behind the centre of equilibrium; the body is protected by a dense covering of feathers, and a thick down next the skin; and the whole organisation is especially adapted for aquatic life. Hence the order is termed *Natatores*.

The following classification of the class Birds has been most generally adopted.

- Order 1. *Raptores*. (*Diurnes*) *Falconidæ*, *Vulturidæ*, *Gypogeranidæ*, (*Nocturnes*) *Strigidæ*.
- Order 2. *Insessores*. (*Dentirostres*) *Laniadæ*, *Merulidæ*, *Sylviadæ*, *Pipridæ*, *Muscicapidæ*, (*Conirostres*) *Sturnidæ*, *Corvidæ*, *Buceridæ*, *Loxiadæ*, *Fringillidæ*, (*Tenuirostres*) *Cinnyridæ*, *Trochilidæ*, *Promeropidæ*, *Meliphagidæ*, *Nectarinidæ*, (*Fissirostres*) *Hirundinidæ*, *Caprimulgidæ*, *Todidæ*, *Halcyonidæ*, *Meropidæ*.
- Order 3. *Scansores*. *Psittacidæ*, *Picidæ*, *Cuculidæ*, *Ramphastidæ*.
- Order 4. *Rasores*. *Columbidæ*, *Cracidæ*, *Phasianidæ*, *Tetraonidæ*.
- Order 5. *Cursores*. *Struthiidæ*, *Dinornidæ*, *Dididæ*, *Apterygidæ*.
- Order 6. *Grallatores*. *Arleidæ*, *Scolopacidæ*, *Rallidæ*, *Charadriadæ*.
- Order 7. *Natatores*. *Anatidæ*, *Colymbidæ*, *Alcidæ*, *Pelecyanidæ*, *Laridæ*.

Aviary (Lat. *aviarium*). A place for keeping birds. In gardens, aviaries for singing birds are generally limited spaces attached to summer-houses or hot-houses, in which a temperature is kept up during winter suitable to the kind of bird or birds in the aviary. When an aviary contains only birds which live in climates analogous to that of Britain, it is formed in the open garden or pleasure ground, each kind of bird having a separate house, or small inclosure covered with netting. The most common exotic singing birds kept in aviaries are canaries; and the most common exotic ornamental birds are turtle doves, and birds of the parrot tribe. The ornamental and curious birds which live in climates similar to that of Britain may be divided into two classes, the terrestrial and the aquatic. Of the former, the most ornamental are the gold and silver pheasants, and the varieties of the common pigeon; and among the latter, the white and black swans, the Muscovy Duck, &c.

Avicula (Lat. *a little bird*). A name applied to a genus of Bivalves, in some of the species of which, the shell, when expanded, resembles a bird flying. The shell is inequivalve, with a rectilinear hinge, notched at the anterior edge for the passage of a byssus; the anterior adductor muscle very small. To the subgenus *Meleagrina* belongs the celebrated pearl oyster (*Avicula margaritifera*). In this subgenus the valves are flatter and nearly equal. The 'mother-of-pearl' or nacreous deposit formed on the inside of these shells and

AVOIDANCE

on the 'oriental' pearls of commerce are preceded by alternate layers of very thin membrane and carbonate of lime, but this alone does not give the pearly lustre, which appears to depend on minute undulations of the layers. Completely spherical pearls can only be formed loose in the muscles or other soft parts of the animal. The Chinese obtain them artificially, by introducing into the living mussel foreign substances, which produce irritation, and are coated with the nacreous deposit. (Woodward, *Manual of Mollusca*.)

Avoidance. In Ecclesiastical Law, signifies the condition of a benefice when void of an incumbent, and is opposed to plenary.

Avoirdupois or Averdupois (Fr. avoir du poids, *to have weight*). The name given to the common system of weights in England, by which goods in general, excepting the precious stones and medicines, are weighed. The standard weight of this country is the grain, which is ordered by Act of Parliament, 5 Geo. IV. c. 74, to be such that 'a cubic inch of distilled water, weighed in air by brass weights, at the temperature of 62 degrees of Fahrenheit's thermometer, the barometer being at 30 inches, is equal to two hundred and fifty-two grains, and four hundred and fifty-eight thousandth parts of a grain.' A pound avoirdupois contains 7,000 grains. The pound is subdivided into 16 ounces and the ounce into 16 drams. The higher denominations are the quarter-hundred, the hundredweight, and the ton; 28 pounds making a quarter, 112 pounds a hundredweight, and 20 hundredweights a ton. The pound avoirdupois is greater than the pound troy; the latter containing only 5,760 grains. But the troy ounce, which contains the twelfth part of 5,760, or 480 grains, is greater than the ounce avoirdupois, which contains the sixteenth part of 7,000, or 437½ grains. The avoirdupois ounce is considered as being the Roman uncia, which, according to Dr. Arbuthnot, contains 437½ grains, though other authorities make it several grains less. The term *averdupois* occurs in some orders of Henry VIII., A.D. 1532; and Queen Elizabeth, in 1588, ordered a pound of this weight to be deposited in the Exchequer as a standard. [WEIGHTS.]

Avoset. A wading bird, characterized by a long recurved bill.

Avowry. In Law, the justification advanced in pleading by one who has taken a distress in his own right when sued in replevin. The avowry must contain a sufficient averment of right to have return. One who justifies as having taken in the right of another, is said to make cognisance. [REPLEVIN.]

Award (from Ital. guardare, Fr. regarder, *to look*). In Law, the judgment pronounced by one or more arbitrators, at the request of two parties who are at variance, for ending the matter in dispute without the decision of a public tribunal. The act of reference to an arbitrator is termed a submission.

Arbitrations are now regulated principally by the Common Law Procedure Act 1364,

AXILLA

which provides for the stay of legal proceedings in cases where the parties have agreed to refer their disputes to arbitration, and also for the appointment of arbitrators and an umpire. Every submission to arbitration by consent may be made a rule of one of the superior courts of law or equity on the application of any of the parties thereto, and any question of law may be referred to the opinion of such court if the arbitrator think fit. When the submission has been made a rule of court, the award may be enforced by attachment. In other cases an action must be brought. Awards may be set aside for various causes, as for corruption, informality, and the like.

Awn (Icelandic *ogn*). A stiff, usually rough, bristle, proceeding from the end or some other part of a leaf, or of a leafy organ; it is the beard of grasses, and often proceeds in those plants from the base of either glumes or pales. An awn is in reality either a vein separating from its parenchyma, or a rigid sharp-pointed barren branch of inflorescence. A part is said to be awned, or aristate, when furnished with this organ.

Awning (Dutch, havenung, *shelter*, as in a haven or harbour). In Horticulture, a temporary covering for plants, generally consisting of cloth of some kind, stretched by means of ropes, cords, or wooden rods, so as to protect fruit trees against a wall, or flowers in a bed. An awning for a tulip bed is the most complete structure of this description, and is so constructed, by means of lines and pulleys, that the sheeting can be either pulled up or let down over a bed of considerable length in two or three minutes.

Axe (A.-Sax. *eax*). A tool used by carpenters, consisting of a cutting edge of steel, followed by a wrought-iron shaft, into which the handle is fixed parallel to the edge; but the handle is made to work in the same plane as the edge instead of being parallel to it, as in the case of the adze.

Axestone. A name sometimes given to Jade in consequence of its being shaped into axes and other cutting instruments by the New Zealanders. [JADE; NEPHRITE.]

Axiferous (Lat. *axis*, *a centre*, and *fero*, *I bear*). A name given to those plants which, like lichens, fungi, &c., consist exclusively of an axis, without any leaves or appendages of it.

Axil (Lat. *axilla*, *the armpit*). That part of a plant where a leaf fits on a branch, forming an angle with it; or where two branches diverge from each other.

Axile (Lat. *axis*). Lying in the axis of anything; as an embryo, which lies in the axis of a seed, that is from the base to the end diametrically opposite.

Axilla (Lat.). In Anatomy, the hollow below the base of the arm, at its insertion into the chest. An interesting region in topographical anatomy, containing important arteries, veins, nerves, glands, &c., which are termed 'axillary.'

Axillary. In Botany, growing in an axil. The term is modified by prefixing different Latin prepositions: thus, *infra axillary*, signifies growing from below the axil; *extra axillary*, on one side of it; and *supra axillary*, from above it.

Axinite (Gr. *ἀξίτης*, an *axe*). An anhydrous silicate of alumina, lime, &c., with boracic acid. The name refers to the form of the crystals, which are generally very oblique rhomboidal prisms, so flat as to appear tabular, and sharp like the edge of an axe. The colour is most commonly brown of various shades, passing into pearl-grey and greyish-black; and the crystals, which have a brilliant lustre, are either transparent or translucent. Very perfect crystals of a clove-brown colour are found near St. Just in Cornwall, and at Lostwithiel, and St. Columb. It is also met with in Devonshire, at Brent Tor, near Tavistock, and on Dartmoor; the principal foreign localities are the Harz, Savoy, St. Gotthard, the Tyrol, the Pyrenees, Norway, Sweden, the Ural, &c.

Axiom (Gr. *ἀξίωμα*, from *ἀξίω*, I demand). In Geometry, a proposition which it is necessary to take for granted, and which therefore admits of no demonstration. The following are among the propositions of this kind enunciated by Euclid: 'Things that are equal to the same thing are equal to one another,' 'The whole is greater than its part,' 'If equals be added to equals, the sums will be equal,' 'Two figures when placed the one on the other entirely coincide, they are equal in every respect.' The formal statement of such propositions is totally useless, or rather tends only to produce obscurity.

AXIOM. In Philosophy, properly that which is demanded, or postulate. It is used, in the mathematical and physical sciences, in the sense of a proposition, to which the assent of the student is demanded without proof, as a foundation for further argument.

Axis. In Architecture, straight line passing through any body on which it may revolve; the axis of a column, for instance, is a straight line drawn down through its centre; the axis of the Ionic volute is a line drawn through the two eyes, front and rear.

Axis. In Botany, that part in plants about which particular organs are arranged. Thus, the stem is an axis for the branches; a branch an axis for the leaves; the rachis, an axis for the divisions of inflorescence; and the receptacle, gynobase, or columella, is the axis of the fruit. The term is also applied to the imaginary point round which parts of any sort are arranged.

Axis. In Mechanics, signifies in general the straight line, real or imaginary, about which a body turns. In this sense it is called the axis of rotation, of oscillation, &c., according to the motion of the body. In Geometry, the axis of a figure is a straight line about which the parts of the figure are symmetrically disposed. Thus, the axis of a cone is the line drawn from the vertex to the centre of the base; and the axis of a cylinder, the line

drawn through the centre of its two ends. In the ellipse and hyperbola, the transverse axis is the straight line drawn through the two foci; and the conjugate axis, that drawn through the centre, perpendicular to the transverse. In general, by the axis of a curve line is meant that diameter which has its ordinates at right angles to it. We also speak of the axes of the coordinates of a curve, meaning the line on which the abscissas are taken.

Axis-cylinder. In Anatomy, the name applied to the central substance of the primitive nerve-fibre.

xis of the Earth. Is that diameter about which it revolves from west (through south) to east.

Axis of Elevation. The line or direction in which rocks have been elevated from below. This line generally governs the *strike* of the rocks [DIP and STRIKE], or the direction of a horizontal line upon them when removed from their natural or original position (which must have been horizontal or nearly so), and inclined to the horizon at a definite angle. [ELEVATION OF ROCKS, and ANTICLINAL and SYNCLINAL.]

Axis in Peritrochio. One of the five mechanical powers, consisting of a peritrochium or wheel fixed immovably to an axle, so that both turn together round the axis of motion. The power is applied at the circumference of the wheel, and the weight raised by a rope wound round the axle. The power gained is the same as that gained by a lever, the longer arm of which is equal to the radius of the wheel, and the shorter equal to the radius of the axle; so that if we suppose the radius of the wheel to be 30 inches, and the radius of the axle 6 inches, a weight of one pound suspended by a rope passing round the wheel would raise a weight of five pounds similarly suspended from the axle.

Axle (Lat. *axis*, Gr. *ἄξω*). The part of machinery which forms the centre of the revolving portion, or the immediate bearing of the revolution of a piece of machinery which revolves on its own centre, is called the axle: the term is extended to the whole of such a piece of machinery, and the word axle is made to apply to the shaft which carries the wheels, or other revolving machinery. An axle may be either fixed to the wheels, or it may turn freely; it may be either ranked, or it may be uniform in its diameter; it may be either concentric with the driving machinery, or it may be at right angles to it, or at an inclination varying according to the wants of any particular case.

Axolotl. A term derived from the Mexican language, and applied to a genus of Perennibranchiate Amphibians, found in the lake of Mexico.

Ayapana. *Eupatorium Ayapana*, a sudorific which has the repute of being a remedy for snake bites.

Aye-aye. The name of a singular nocturnal quadruped of Madagascar, indicative of its

AYMESTRY LIMESTONE

peculiar cry; it is placed by Cuvier in the Rodent order, under the generic name *Chœromys*, from the hand-like structure of the hinder feet; a structure which approximates the genus to the monkey tribe, or *Quadrumana*, in which other naturalists have correctly placed it. [*CHœROMYS*.]

Aymestry Limestone. An impure clayey limestone often fifty feet thick, distinguished by the presence of some particular fossils (the *Pentamerus Knightii*, *Terebratula Wilsoni*, *Linula Lewisii*, and some others), and occupying a definite position near the top of the Silurian series in England. The Aymestry limestone lies immediately below the upper Ludlow shales and sandstones. It is subcrystalline in texture.

Azadrine. An alkaloid found in the *Melia Azadirachta*.

Azalea (Gr. *ἄζαλος*, *parched*). A group of Ericaceous shrubs allied to *Rhododendron*, and distinguished, amongst other points, by having five instead of ten stamens. Though beautiful garden shrubs, the plants have deleterious properties, one of them, *Azalea pontica*, being charged with the destruction of the army of Xenophon, whose soldiers had eaten freely of honey derived principally from the flowers of this plant. Cattle and sheep also suffer from browsing on its leaves.

Azimuth (from the Arabic). A term used in Astronomy, to denote the arc of the horizon intercepted between the meridian and the vertical circle passing through a star or other celestial body; or the angle made at the zenith by the meridian and the vertical circle in which the body is situated. The azimuth may be counted either from the north or the south point of the horizon; modern astronomers seem to prefer beginning at the north point, and counting eastward and westward to 180°; but it is not one of those elements usually observed in astronomy, being easily deduced from the declination, which can be measured much more conveniently and accurately. In trigonometrical surveys, however, on the earth's surface, the accurate determination of the azimuth of an object is an operation of very great importance. It is usually made with the theodolite.

Azimuth Circles or Vertical Circles. Are great circles of the sphere passing through the zenith, and intersecting the horizon at right angles.

Azimuth Compass. A compass used at sea for finding the horizontal distance of the sun or a star from the magnetic meridian.

AZYMITES

Azimuth Dial. A dial of which the stile or gnomon is perpendicular to the plane of the horizon. It is so called because the shadow marks the sun's azimuth.

Azerythrin. A crystalline substance contained in various lichens. It closely resembles orcin.

Azoleic Acid. A product of the action of nitric acid on oleic acid.

Azolitmine. A dark red substance forming a great part of the colouring material of litmus; its chemical formula is, according to Kane, $C_{14}H_{10}O_8N$.

Azomarie Acid. A product of the action of nitric acid upon resin.

Azorite. A columbate or tantalate of lime occurring in minute square prisms in an albitic rock in the Azores (whence the name).

Azotane. Sir H. Davy proposed to designate the compounds of chlorine by the termination *ane*, and consequently distinguished the compound of chlorine and azote, or chloride of azote, by the above name.

Azote (Gr. *ἄζωγ*, and *ζωή*, *life*). A simple gaseous body, unfit for respiration; it forms four-fifths of our atmosphere. [NITROGEN.]

Azotic Acid. A synonym of Nitric Acid.

Azotised Principles. In Chemistry, the term is chiefly applied to substances containing nitrogen, and used as aliments: many of them are common to animals and vegetables.

Azuline. A fine permanent blue dye made from certain constituents of coal tar.

Azulmic Acid. A brown substance deposited from an aqueous solution of cyanogen on exposure to light.

Azure (Fr. *azur*, *blue*; Ital. *azzurro*). In Heraldry, one of the colours, or tinctures, employed in blazonry. It is equivalent to sapphire among precious stones, and Jupiter among planets. In engraving, it is represented by horizontal lines.

Azure. In Painting, a sky-coloured blue. That made of lapis lazuli, called ultramarine, is of great value to the painter.

Azure Copper Ore. Blue carbonate of copper. [CHESYLITE.]

Azure-stone or Azurite. [LAZULITE.]

Azygos (Gr. *ἄζυγος*, *unpaired*). In Anatomy, some single muscles, bones, veins, &c., are so called.

Azymites (Gr. *ἄζωγ*, and *ζωή*, *leaven*). In Ecclesiastical History, Christians who administer the sacrament with unleavened bread. The Latins, Armenians, and Maronites are so called.

B

B. The second letter in all European alphabets, and in those of most other languages. B is one of the letters called labial, because the principal organs employed in its pronunciation are the lips. It has a close affinity to the

other labial letters P and V; and by the Saxons it is confounded with the former, and with the latter by the modern Greeks, Spaniards, and Gascons. Hence the sarcastic remark, that in Gascony 'vivere' and 'bibere' are the

same thing. Among the Greeks and Hebrews, B signified 2; among the Romans 300; with a dash over it, it denoted 3,000, and with a kind of accent below it 200. The Romans also used it in inscriptions as an abbreviation for *Baccho*, *Beleno*, *Benemerenti*, &c.; B.B. for *bene bene* (i. e. Optime), B.L. for *lector benevole*, B.F. (affixed to decrees or *senatus consulta*) for *bonum factum*. In modern times also it is used as an abbreviation for *before*, as B.C. (before Christ); and for *bachelor*, as, B.A., LL.B., B.D. (bachelor of arts, of laws, of divinity). In the chemical alphabet, according to Raymond Lully, it denotes mercury.

B. One of the notes in the English musical scale, corresponding to the French *Si*. The Germans, by B standing alone, understand B flat; they call B natural H.

Baal or **Bel** (Heb.). A Phœnician and Syrian god. The term, which is common to all the Eastern languages, signifies lord or master; and the system of Baal-worship was an adoration of a supreme being under the more attribute of power. Into this form of heathenism the Jews showed a frequent tendency to relapse; and it was the religion adopted by Jeroboam for the ten tribes which had revolted with him from Rehoboam. Some account of the worship of Belus (or Baal) at Babylon is given by Herodotus, book i. 181, &c. Among other sacrifices human victims were sometimes offered up on his altars. The adoption of his name for members of noble families (as in the Carthaginian names, Hannibal, Hasdrubal, &c., and in Belshazzar, &c.) sufficiently proves the devotion of eastern nations to this divinity and the wide extent of his worship. (Selden, *De Diis Syriis*. Shuckford's *Connection*, b. v.)

Baal-berith. The god of the Shechemites (Judg. viii. 33).

Baal-peor or **Baal-phégor**. A god of the Moabites and Midianites (Num. xxv. 3).

Baalzebub. [BAALZEBUB.]

Babel (Heb.). A tower, which the posterity of Noah began to build in a plain in the land of Shinar, the attempt being followed by their dispersion and the confusion of tongues. (Genesis xi.) It is generally supposed that the site of Babel was afterwards occupied by the city of Babylon, where Herodotus saw a structure, which he describes as consisting of eight towers, rising within and above each other and each seventy-five feet high (Herod. i. 181), and which is fancifully supposed by some to have been built from the ruins of the tower. The Orientalists maintain that the original tower was 10,000 fathoms or twelve miles high. St. Jerome asserts, on the authority of eye-witnesses who had examined the ruins of a tower at Babylon, that it was four miles high, and there are other statements still more extravagant. The accounts of modern travellers, who pretend to identify the ruins found on or near the site of ancient Babylon with the town of Babel, are very inconsistent and contradictory. (Rich's *Travels*; Rennel's *Remarks on Herodotus*; Rawlinson's *Herodotus*, vol. ii. p. 574.)

Babiana. A genus of Cape plants belonging to the natural order *Iridaceæ*, having sword-shaped leaves, and spikes of crocus-like flowers. The name is derived from *Babianer*, a term given by the Dutch colonists to these plants in consequence of the avidity with which their fleshy root-tubers are devoured by the baboons.

Babillard (Fr.). The name of a small frugivorous Passerine bird, the *Curruca gurrula*: also called the white-breasted or babbling fauvette, lesser whitethroat, and nettle-creeper.

Babingtonite. A silicate of iron and lime. It occurs in dark greenish-black crystals with a vitreous lustre, on the Albite of Norway; and in large laminated crystals imbedded in white Quartz, in one of the Shetlands. Named after Dr. Babington.

Bablah. An astringent dye-stuff imported from the East Indies and from Senegal; it has been used for dyeing drabs, as a substitute for more expensive materials. It is the shell of the fruit of the *Mimosa cineraria*.

Baboon (Fr. *babouin*; Dutch, *bavian*). The monkeys, or quadrumana, which have projecting ridges above the eyes, long and truncate muzzles, cheek-pouches, ischiatic callosities, and generally short tails. They are composed of the genera *Papio* and *Cynocephalus*.

Babyroussa. The name of an animal of the hog kind (*Sus babirussa*, Cuv.) inhabiting the forests of the Indian Archipelago, with longer legs and tusks than the other species of hog; both the upper and the lower tusks curve upwards and backwards, and serve as a defence to the eyes while the animal forces its passage through the entangled jungles.

Bacca (Lat.). A berry; usually a succulent fruit containing several seeds. In its more exact application it is a succulent fruit filled with pulp, in which the seeds lie loosely, as in the gooseberry.

Baccalaureat or **Bachelorship**. The first or lower degree in any faculty, conferred in the English, French, and other universities. At Oxford and Cambridge it is conferred after examination, to which those students alone are admissible who have pursued the prescribed course of study, and (in the ordinary case of Bachelor of Arts) kept the university terms for the space of three years; and sometimes by extraordinary diploma on persons unconnected with the university. The former class are called *Baccalauræi Formatæ*, the latter *Baccalauræi Currentes*. In France the degree of *Baccalaureat* (*Baccalauræus Literarum*) is conferred indiscriminately upon such natives or foreigners as, after a strict examination in the classics, mathematics, and philosophy, are declared to be qualified. In the German universities, the title 'Doctor Philosophiæ,' has long been substituted for *Baccalauræus Artium* or *Literarum*. In the middle ages, the term *Baccalauræus* was applied to an inferior order of knights, who came into the field unattended by vassals; from them it was transferred to the lowest class of ecclesiastics; and thence again, by Pope Gregory IX., to the universi-

tion. There are few words whose origin has been more controverted than that of *Baccalaureat*; and both the military and literary classes have asserted their claims to this honour with equal zeal and ingenuity. While the former maintain that it is derived either from the *baculus* or staff with which knights were usually invested, or from *bas chevalier* (an inferior kind of knight), the latter trace its origin to the custom which prevailed universally among the Greeks and Romans, and which was followed even in Italy till the thirteenth century, of crowning distinguished men with laurel: hence the recipient of this honour was styled *Baccalaureus* (quasi *baccis laureis donatus*).

Baccha. In Entomology, a genus of the order *Diptera* and family *Syrphidae*. The two basal joints of the abdomen are long and slender, with the remaining joints depressed and broad; they are of bronze-colour marked with yellow, and are found upon flowers in the neighbourhood of London.

Bacchanalia (Lat.). Festivals in honour of Bacchus. Such legends as those of Lyncurgus and of Pentheus indicate the opposition made to the introduction of these festivals, which were imported from eastern countries. (Grote's *History of Greece*, i. p. 38, &c.) They consisted originally of a grand procession, in which the priests and priestesses of Bacchus bore the principal part, and were accompanied with games, spectacles, and theatrical representations. But, at a later period of Grecian history, vice, debauchery, and licentiousness became their distinguishing characteristics; and Plato (*De Leg.* l. i.) asserts that during the celebration of these festivals he has seen the whole Athenian populace in a state of drunkenness. At Athens, there were two principal Bacchanalia held annually: viz. *Dionysia* or *Majora*, celebrated in the city about spring time; and *Lenæa* or *Minora* (so called from *Λύκω*, a winepress), celebrated in the country during autumn. On these occasions, the Bacchæ or priestesses of the god ran up and down the mountains in a frantic manner (*Stat. Theb.* vi. 92), clad in doe-skins, with spears in their hands, bound at the points with ivy-leaves (*thyrsi*), and using the wildest gestures and exclamations. (See the *Bacchæ* of Euripides.)

These festivals were introduced from Greece into Etruria, and thence by an easy transfer into Rome, where they were at first celebrated chiefly by young men on their laying aside the toga pretexta for the toga virilis. But they soon after extended among all classes of the community; and the crimes practised at their celebration became so great, that the senate (A.U.C. 566) came to the resolution of abolishing them entirely. (Cicero, *De Legibus*, ii. 15.) But the *Liberalia*, a more harmless festival, still continued to be celebrated yearly in March. (Ovid, *Fast.* iii. 713.)

Bacchus (Lat.; Gr. *Βάκχος*, or *Ίακχος*, perhaps from *βαλῶ*, *I shout*). This name, arising probably from the cries which accompanied his worship, was adopted by the Latins to signify

the god commonly known to the Greeks as *Dionysus* [which see].

Bachelor. In the English universities, the lowest degree in arts, law, divinity, medicine, and music. It is, like other university honours, of French origin. For the various derivations that have been suggested for this word, see *BACCALAUREAT*.

BACHELOR. In Heraldry, the lowest order of knighthood. [KNIGHT.]

BACHELOR. In some of the Livery Companies of London, is one who is not yet admitted of the livery; also called *grooman*.

Bacillareæ. A small group of diatomaceous *Algae*, having an extremely simple structure, and in part the same as what are called *Cymbellæ*. They stand on the limits of the animal and vegetable kingdoms, and are said to have a power of spontaneous motion.

Bacillus (Lat.). A name given to the cotyledon of the hyacinth by Link. The little bulbs found on the inflorescence of some plants.

Back. A reservoir or cistern. The *liquor back* in a brewery is the water reservoir.

Back and Fill. To keep a ship in the middle of the stream of a narrow river, by alternately advancing ahead from one shore and moving backwards from the opposite shore, while the stream carries her along, the wind being contrary to the direction of the stream.

Back (from the Sax. *bæc*) of a *Ship*. In Architecture, the upper faces of the hip rafter between the two sides of a hipped roof, so formed to an angle as to be in the same plane with the rafters on each side of it.

Back the Oars. To row the oars backwards.

Backer. In Architecture, a term used to denote a narrow slate laid on the back of a broad square-headed slate, where the slates begin to diminish in width.

Backgammon. A game played with dice by two persons on a table divided into two parts, upon which there are 12 black and as many white spaces, called *points*. Each player has 15 men, black and white, to distinguish them. This game is of Welsh origin, and is said to have been invented in the period preceding the Conquest. (*Gloss. ad Leger Wallic.* cited by Henry, vol. iv. p. 404.) In backgammon, though much depends on chance, still great skill may be displayed in the course of the game. Hoyle, the received oracle in these matters, has evinced great accuracy in calculating the odds of backgammon, and has embodied a variety of useful rules and instructions respecting it.

Back-staff. An instrument used before the invention of the quadrant and sextant, for taking the sun's altitude at sea. In using it the observer turned his back to the sun, whence the instrument had its name. It was invented by Captain John Davis, about the year 1590, and is now obsolete.

Back-stays. In Sea language, ropes stretched from the topmast, top-gallant mast, and royal-mast heads to the starboard and

BACONIAN PHILOSOPHY

port sides of the ship; their use being to support the masts, and second the efforts of the shrouds. [RIGOROUS.]

Baconian Philosophy. The system propounded by Francis Bacon, Lord Verulam. It is usual to speak of this philosophy as if it were the invention of its illustrious founder—as if the method of induction were a mode of philosophising unknown before his time, and in direct opposition to preceding systems, especially that of Aristotle; this opinion is erroneous. Aristotle has in many parts of his works clearly and satisfactorily explained the inductive method, and has himself, in his physical writings, given examples of its application. Lord Bacon's distinguishing merit consists rather in the attention which, by his splendid eloquence, his wonderful power of illustration, his comprehensive views of the relations of the sciences to each other, and his unhesitating faith in the boundless progressiveness of human knowledge, he succeeded in awakening in the minds of his countrymen; than in any philosophical discoveries properly so called. No man, we admit, ever obtained a clearer insight into the nature and province of inductive research; no man, certainly, has laid down with such rigour and accuracy the rules for its successful prosecution. The various modes of experimenting and observing (in the language of Bacon *instances*) are classed under twenty-seven heads; and the circumstances under which each kind is applicable are stated with great fulness and accuracy. This is done in the second book of his *Novum Organon*, the first consisting of aphorisms on the errors of the human intellect generally, and in particular of preceding philosophical systems. These delusions, under the name of idols, he reduces to four classes: the *idols of the tribe*, or those common to human nature generally; the *idols of the cave*, or those generated by individual peculiarities; the *idols of the marketplace*, produced by the incorrect use of words in ordinary discourse; and lastly, the superstitions introduced by false and visionary systems of philosophy, to which the name is assigned of the *idols of the theatre*. His own method he designates as holding an intermediate place between the merely empirical and the dogmatical schools. 'While the one,' says he, 'like ants, content themselves with heaping up materials for immediate use, the latter, after the manner of spiders, spin webs out of their own brain: there is a middle and a better way—that of the bee, which derives, indeed, its material from the flowers of the garden and the field, but converts and digests it by its own proper virtue.' These two books of the *Organon* form the second great division of his projected undertaking, the *Instauratio Magna*, or *Reform of Philosophy*, and relate to the interpretation of nature. The treatise *De Augmentis Scientiarum* (*Of the Advancement of Learning*) constitutes the first division: the third was to consist of a history of the phenomena of the universe: the fourth (*Scala In-*

BAGPIPE

tellectus) was to comprise an account of the processes of the human understanding, with examples from various sciences: in the fifth was to be contained the introduction to the *Philosophia Secunda*, or *Active Philosophy*, which, as the combined result of history and experience, was itself to constitute the sixth and last division. (See his *Distributio Operis*; Bacon, *Works*, 4to ed. vol. iv.) Of this mighty work Bacon only completed the first two divisions. For a comprehensive and impartial estimate of the value of the Baconian philosophy, the German scholar may consult Tennemann's *Geschichte der Philosophie*, 10ter band (Leipzig, 1817), Stewart and Playfair, *Preliminary Dissertations* (*Encyclopædia Britannica*), and the elaborate edition of Bacon, by Spedding, Ellis, and Heath, now in progress (1862).

Bactris (Gr. *βάκτρον*, a cane). A genus of palms with spiny slender stems and pinnated leaves. Their fruit is succulent, and manufactured into a kind of wine. Walking sticks, made from their stems, are known as Tobago canes.

Baculites (Lat. *baculus*, a stick). A genus of fossil Tetrabranchiate Cephalopods, the chambered shells of which are quite straight, but differ from those of the Orthoceratites in having sinuous or undulated partitions with lobated margins: in this structure they are allied to the Ammonites.

Badger. [MELLS.]

Badister (Gr. *βιβίωτης*, a walker). In Entomology, a genus of the order *Coleoptera*, and family *Harpalidae*. This genus, with some others, forms a leading group among the carnivorous beetles.

Bagasse (Fr.). The sugar-cane in its dry crushed state, as used for fuel in the colonial sugar-houses.

Baggage (Fr. *bagage*). In Military language, the clothes, tents, provisions, and other necessities belonging to an army.

Bagging. In Agriculture, a mode of reaping corn or pulse with a hook, in which the operator effects his object by striking the straw or haulm, instead of drawing the hook through it. In other words, it is separating the straw or haulm from the root by chopping, instead of by a drawing cut.

Bagpipe. This instrument appears to be of very ancient origin, and is similar to the *tibia utricularia* described by Blanchinus. A representation of it is given by Luscinus in his *Musurgia* (1686), whence it appears that at that time the instrument was similar to that now in use. It consists of a leather bag, inflated through a valved tube by the mouth (or a bellows), and of three pipes; two of which give only one note each, and are called the great and little drone; and the third, somewhat like the oboe, has eight finger-holes. The small Irish bagpipe is a much less powerful instrument than the great Highland bagpipe, still used, but chiefly at dances, in the Highlands of Scotland. In the southern parts of Italy, especially in Calabria, the bagpipe is still a common instrument. And some passages

in *Don Quixote* prove that it was used in Spain down to the time of Cervantes.

Bagationite. A variety of Allanite, named after Count Bagation.

Bagshot Sands. The beds thus named belong to the middle Eocene group of tertiaries as now determined in England. The upper division of the Bagshot sands is thick, and agrees either with the lower Barton clay sands or with the upper Bracklesham beds. The middle division corresponds with the Bracklesham series and Barton clay, but is thin and very fossiliferous, the lower division distinctly underlies the Bracklesham series, and forms the base of the middle Eocene series. These sands are developed on Bagshot Heath.

Baierine (Ger. *Baieru, Bavaria*). The name given by Damour to a variety of Columbite found in Bavaria.

Baikalite. A crystalline variety of Sahlite found in Siberia at the mouth of the Sijumanka river, which falls into Lake Baikal.

Bail (Old Fr. *bailler*, to deliver or give up, said by Dufresne to be derived from Lat. *bajulus*, a bearer, a derivation adopted by Mr. Wedgwood, *Dictionary of English Etymology*). In Law, is the liberation of one in custody, whether for a civil or criminal cause, on surety taken for his appearance at a day and place certain. In civil cases bail is chiefly of two kinds, called bail to the sheriff, and bail to the action; or, in other terms, bail below and bail above. When a person is arrested upon an affidavit made that he is indebted to the plaintiff in the sum of 20*l.* or upwards (which, since the Act 1 & 2 Vict. c. 10, must also state that there is probable cause for believing that the defendant is about to quit England), he has then in order to regain his liberty (unless previously discharged under a judge's order), to execute a bail-bond to the sheriff, the condition of which is, that he will at the proper period put in special bail, which amounts to an appearance in court; at this period he either puts in special bail, who are two or more persons, who undertake generally that if the defendant lose the verdict he shall pay the amount awarded against him, or render himself to custody, or that they will do it for him. In default of special bail he returns again into custody.

Bail, in cases of felony, is taken by committing magistrates at their discretion in cases where the evidence against the prisoner is not such to raise a strong presumption of his guilt; in cases of misdemeanour, except such as are enumerated by the Act 11 & 12 Vict. c. 42, the magistrates are bound to take bail.

Bail-bond. In Law, a deed executed by a party arrested formerly on mesne process, or a debtor arrested as about to abscond (14 & 15 Vict. c. 52), and two persons as his sureties, to the sheriff, conditioned for his causing special bail to be put in. If the defendant neglect afterwards to put in and perfect such bail, the plaintiff usually takes from the sheriff an assignment of the bail-bond, and proceeds against the defendant in a separate action.

Baillie. The name by which the municipal magistrates of Scotland are designated. The term is synonymous with *alderman*.

Baillif (Fr. *bailli*). Properly, anyone to whom authority is entrusted: whence it came to signify more generally 'deputy,' and was applied to those officers who, by virtue of deputation either from the sheriff or the lords of private jurisdictions, exercised within the hundred, or whatever might be the limits of their bailiwick, certain judicial and ministerial functions. With the disuse of private and local jurisdictions, the meaning of the term became commonly restricted to such persons as were deputed by the sheriff to assist him in the merely ministerial portion of his duty, such as the summoning of juries and the execution of writs. These persons are called bound bailiffs, so termed from the obligation which they enter into to indemnify the sheriff against the consequences of his responsibility for their right conduct in the discharge of their duty.

Bailiwick (Fr. *bailli*, and Lat. *viciu*, a village). The dwelling-place or district within which a bailiff exercises his deputed authority: thus, a county is said to be the bailiwick of the sheriff.

Bailment. In Law, is a delivery of goods in trust, upon a contract, express or implied, that the trust shall be faithfully executed on the part of the bailee, or receiver. Transactions with carriers, agents, pawnbrokers, and many other mercantile proceedings are affected by the law of bailment.

Bairam. A Mohammedan feast, instituted in imitation of the Easter of the Christian church, and following the Rhamadan, or month of fasting, which answers to our Lent. In consequence of the Turkish mode of reckoning by lunar months, these periods fall successively in all the seasons during a cycle of thirty-three years. Sixty days after the greater follows a second feast, termed the lesser Bairam.

Bajaderes. This name, which is supposed to be a corruption of the Portuguese *bailadeira*, is applied to the Indian dancing girls, who, under various appellations, are employed partly as priestesses, partly by the grandees of India to cheer their festivities and minister to their pleasure. Their dress consists of costly materials, tastefully arranged, and their movements are graceful. In their whole character and proceedings, they bear a strong resemblance to the *Hierodoulai* of the Greeks.

Bajulus (Lat.). An officer of the Roman emperors, in the court of Constantinople, to whom the education of a prince was entrusted. There were several grades of Bajuli.

Bæna (Lat.; Gr. *φάλανα*). The Greenland whale; also a generic term, comprehending the species which agree with it in the presence of whalebone in the mouth, and the absence of dorsal fin.

It is to this genus that the whale, properly so called, or large-whalebone whale (*Balæna mysticetus*, Linn.), belongs, the value of which is such that large fleets are fitted out expressly

BALÆNA

for its capture. The food of the whale consists of small molluscous and crustaceous animals, but chiefly the *Clio borealis*; and as these animals abound only in the Arctic seas, the whale cannot be expected to frequent for any length of time those latitudes in which its food is scarce or altogether wanting. The long-continued annual destruction of the *Balæna mysticetus* has greatly diminished the numbers of this species, and driven those which remain to the extremest limits of the northern seas where their means of subsistence can be obtained.

The large-whalebone whale is often spoken of as the largest of existing animals, but it is inferior in magnitude to the so-called small-whalebone whale (*Balanoptera*). The latter attains the length of from ninety to a hundred feet; while the ordinary dimensions of the true whale are from fifty to sixty feet in length, and from thirty to forty feet in circumference. The terms 'large whalebone' and 'small whalebone' relate to the size of the whalebone or baleen-plates, which is always much greater in the genus *Balæna* than in *Balanoptera*; and it is this structure, combined with the greater amount of blubber in the true whale, which renders it an object of so much more value to the whale-catchers; while its less courageous habits, and less violent efforts to escape when wounded, make it a more sure and safe prey than the small-whalebone whale.

The true whale is chiefly remarkable for the immense size of its head, which constitutes a full third of the entire length of the animal: it is narrow above, but very broad below, where it consists chiefly of a large underlip, which rises five or six feet, and completely overlaps the upper lip: the eyes are very small and are placed just above the angles of the mouth. The external opening of the ears is scarcely perceptible. The pectoral fins are of moderate size, and placed about two feet behind the angles of the mouth. The neck is indicated by some furrowing of the skin, but there is no constriction. The greatest circumference of the cylindrical body is a little behind the pectoral fins. The tail-fin consists of two lobes of great breadth, measuring twenty feet across from tip to tip in a full-grown specimen; and wielded by muscles of enormous power. It is this part which constitutes the sole organ of offence and defence in the whale, for it has no teeth wherewith to bite or lacerate; a single blow of the tail well delivered suffices to cut a stout boat in two, or to send it whirling through the air.

The plates of whalebone are the substitutes for teeth in the mouth; they have a similar mode of development from a pulp and external membrane, and differ only in form, and in a less proportion of earthy matter in their composition. They are arranged vertically and transversely, in two series, consisting each of three hundred plates, descending from the palatal surface of the upper jaw, and terminating in a fringe of coarse hairs on their oblique lower and inner margins, which hairs are in

BALANCE

contact with the upper surface of the bulky tongue when the mouth is closed. It is thus that the mechanism of the sieve is realised on an enormous scale; and while the water gulped at each successive mouthful is drained off through the interstices of the baleen plates, the molluscous and crustaceous animals are retained bruised into a pulp between the muscular tongue and coarse fibres of the whalebone, and swallowed. The area of the gullet corresponds with the minute character of the food, and is relatively smaller in the whale than in any other animal. The stomach is divided into four cavities; the intestinal canal is long and narrow, and provided with a short and simple cæcum.

The whale has usually but one young at a birth, and brings forth in the early spring. The period of gestation is unknown; that of suckling lasts a year. In this stage of their growth the young are called *short heads* by the whale-fishers; at two years old, and until they are able to find their appropriate food in due abundance, they are termed *stunts*; when they begin to get fat, and until they have arrived at their full size, they are called *skull-fish*.

The interesting details of the profitable but perilous occupation of whale-fishing will be found most amply and correctly given in Scoresby's *Account of the Arctic Regions*, from which many popular narratives have been compiled. The baleen and the blubber are the only parts of the animal of any commercial value, and the quantity of both yielded by these enormous animals is of course considerable. The length of the largest whalebone plates in a whale of sixty feet is as much as twelve feet; and the blubber of such a one will yield more than twenty tuns of pure oil, the proportion of oil to the blubber from which it is extracted being as three to four. The blubber is principally accumulated at the circumference of the body, beneath and in the extended tissue of the skin; an immense quantity of fine oil is also lodged in the cellular substance of the tongue; and the coarse and porous bones, particularly the lower jaw, are full of oil.

Balænicæps. A remarkable bird, which has been described by the accomplished ornithologist Mr. John Gould, from the upper part of the White Nile in Eastern Africa. Its bill, much longer than the head, is robust and broad, and terminates in a powerful hook; the tip of the lower mandible is truncated. The wings are very powerful.

Balænce (Lat. *bilanx*, from *bis*, and *lanx*, a *dish*, i.e. an instrument with two scales, hanging from a beam). A machine for weighing substances. The process of weighing may be performed in various ways, and accordingly there are several kinds of balances; as the common balance or scales, the bent-lever balance, the spring balance, the steelyard, the hydrostatic balance, &c. [for which see the respective words]. The term is also applied to any apparatus employed for comparing the intensities of very small forces, as the electric balance, the balance of torsion, &c.

BALANCE

Neglecting the mere circumstance of construction, and the particular methods of suspension, the balance may be represented thus:—

A and B are the points from which the scales are suspended at the extremities of the beam, C the point of support, G the centre of gravity of the beam, D the point in which the straight line C G intersects the straight line joining A and B.

The properties required in a good balance are *sensitiveness* and *stability*. The balance must be sensitive; that is to say, when it is properly poised a very small addition of weight to either scale should disturb the equilibrium, and cause the beam to turn; and it must be stable, that is to say, when the equilibrium has been disturbed the beam should quickly return, and oscillate about the position of rest.

In the construction of a good balance it is of importance that the beam be as light as possible consistent with inflexibility; for not only the inertia, but also the friction, is increased in proportion to the weight, and the sensibility consequently diminished. A cylinder of steel, passing through the centre of the beam at right angles, forms the axis; and its extremities, ground into sharp edges on the lower side, serve as the points of support. The two edges must be accurately in the same straight line, and turn on smooth planes of agate or polished steel carefully levelled. The scales should likewise be suspended from the extremities of the beam by agate planes resting on knife edges. A needle, or tongue, is usually attached to the beam, pointing directly upwards, or downwards, when the beam is horizontal, for the purpose of indicating the deviations of the beam from the horizontal position, on a graduated scale. It is better, however, to bring the arms to terminate in points, and to place a divided scale behind each; in this way the slightest deviation of the beam will be rendered evident, if the zeros of the scales are placed exactly in the same level. The scale is indispensably necessary, because the balance, if very sensitive, would require a long time to come to rest; but it is known to be poised, when the excursions of the needle on both side of the zero of the scale are equal. In order to preserve the knife edges, the beam, when not in use, is supported on rests. Props should also be placed under the scales while loading or unloading the balance. The whole apparatus must be placed under a glass case, to protect it from the disturbing influence of currents of air.

The sensitiveness of a balance constructed with due care, according to the principles now explained, may be carried to an almost inconceivable extent. Analytical balances are usually made to carry 1000 grains in each pan, and to turn with the $\frac{1}{1000000}$ th part of a grain.

There are several large balances in use at

BALANCE OF POWER

the Royal Mint, calculated to weigh from 1,000 to 5,000 ounces troy; some of them are of excellent construction, turning, for instance, with one-tenth of a grain, when loaded with 1,000 ounces in each scale, or with one nine-millionth part of the weight.

Chinese Balance. This is formed of a slender tapering rod of wood or ivory, about a foot in length. A silk thread passed through a hole perforated nearer one of its extremities than the other serves as the point of suspension. The balance has thus two unequal arms. From the extremity of the shorter a small scale is suspended to hold the substance to be weighed. A sliding weight passes along the other arm, on which divisions are marked; and when the counterpoise is made, the distance of the standard weight from the fulcrum indicates the weight of the substance. In order to procure a greater range, the rod has generally four holes or points of support, at different distances from the extremity, and a corresponding set of divisions is marked on each of its four sides. The principle of this machine is exactly the same as that of the common steelyard.

The *Danish Balance*, much used in the north of Europe for weighing coarse commodities, is usually formed of an iron bar, or a batten of hard wood, having a lump of lead at one of its extremities. The goods are fixed in a hook at the other end; and the whole is suspended through a loop of cord, which is passed backwards and forwards under the rod till equilibrium is obtained. The weight of the goods then to the weight of the lead reciprocally their respective distances from the loop.

Balance, Automatic. [COIN-WEIGHING MACHINE.]

Balance of Power. In Politics, a system by which the relative power of different states and alliances is so maintained as to render any extensive derangement improbable. The idea of preserving a balance of power naturally suggested itself to statesmen in ancient Greece, where so large a number of independent states with opposing interests existed on a narrow territory. In Europe, this portion of political science scarcely began to be understood until the sixteenth century; since which time the maintenance of the balance of power has formed a favourite object, often pursued with unreasonable avidity, by those who have controlled the international relations of Christendom. The great aim of neutral politicians during the century was to establish a balance between the power of France and that of Austria: the latter, united with that of Spain, was so great as to cause much anxiety. But after the commencement of the seventeenth century the power of France steadily increased, and that of Austria abated. Cromwell's alliance with Mazarin was the last result of the ancient system: for the alliances of Charles II. with the French were for personal objects, and were strongly reprobated by all European statesmen. At the end of the seventeenth century France stood predominant, and it became the great problem of

BALANCE OF ROBERVAL

European politics to find a counterpoise to her influence. This was the aim of William III., Eugene, and the Whigs under Queen Anne; and the treaty of Utrecht in 1713, which acknowledged the French supremacy in Spain, was condemned as one of the severest blows ever struck at the balance of power. Nevertheless, this fear, like so many others sedulously cherished by speculative statesmen, proved to have little foundation. The power of France remained stationary during the eighteenth century, while the forces of Austria, Russia, and Britain increased; and Prussia suddenly arose, from a third-rate Power, to the lowest, but still a respectable position, among the first-rates. During that century the alliances were formed with no very steady regard to the balance of power: France and Austria were usually, but not uniformly, rivals. In 1756, the three great Continental Powers were united in a fruitless endeavour to crush the new state of Prussia. The wars of the French revolution entirely altered the ancient equilibrium; it was restored by the congress of Vienna; and the long maintenance of that peaceful arrangement certainly speaks in favour of the sagacity of its constructors. At present Europe is divided, singularly enough, by two different sets of causes, producing different alliances, or rather tendencies towards alliances, for mutual defence. From 1830 to 1850 it was supposed that the opposition between despotic and constitutional principles would range on the one side, Austria, Russia, and Prussia; on the other, England, France, Belgium, Holland, and the other states which enjoy constitutional governments. But since the establishment of the French empire of 1852, new combinations have arisen, the issue of which it is impossible to predict. The modern policy of non-intervention must also have its influence in modifying the old theory.

Balance of Roberval. A mechanical paradox devised by the French mathematician Roberval, in the seventeenth century. The instrument still deserves a place on the lecture-table, since it illustrates in a striking manner the mechanical theory of couples. It consists of a parallelogram, $ABCD$, whose opposite sides, AB and CD , turn around two fixed points, E and F , at their centres. From the

other pair of opposite sides, AD and BC , project two fixed bars, GI and HK . The paradox consists in the fact that two equal weights, P and Q , will hold each other in equilibrium no matter from what points of these bars GI , HK , they may be suspended. Poincaré, the inventor of the theory of couples, was the first to give a really scientific explanation

BALANCE OF TRADE

of the paradox (see his *Éléments de Statique*). A description of Roberval's balance is given in the *Mémoires de l'Acad. Roy. des Sciences*, t. x. p. 494 (Paris, 1730).

Balance, Roman, or Steelyard. [STEELYARD.]

Balance of Torsion. A machine invented by Coulomb for measuring the intensities of electric or magnetic forces, by establishing an equilibrium between them and the force of torsion. Conceive a metallic wire suspended from a fixed point, and kept stretched by a small weight attached to its lower extremity; where also a horizontal needle or lever is fixed, which may be rendered magnetic, or is so formed that one of its ends is a conductor and the other a non-conductor of electricity. The force is brought to act on the extremity of this lever, and its intensity measured by the length of the arc which the needle passes over, reckoning from the point of repose; or an index may be attached to the upper extremity of the wire, and the force measured by the number of degrees through which it can be turned before the lower lever begins to move. The force of torsion is inversely proportional to the length of the wire, and directly to the fourth power of its diameter. The wire must therefore be of considerable length (two or three feet for example), and very fine; and also formed of a substance possessing considerable elasticity. Brass wire is greatly preferable to iron wire; and in some instruments recently constructed a fine thread of spun glass has been used instead of metallic wires, at the suggestion of the late Professor Ritchie. One of the most interesting applications of the torsion-balance was that made by Cavendish to measure the force of attraction of two leaden spheres, in his celebrated experiment to determine the mean density of the earth.

Balance of Trade. The term commonly used to express the difference between the value of the exports from and the imports into a country. The balance is said to be favourable when the value of the exports exceeds that of the imports, and unfavourable when the value of the imports exceeds that of the exports. The notion was once entertained that the prosperity of a country depended on exporting merchandise exceeding the value of the imports, and receiving the balance in the precious metals. This mode of estimating the balance of trade, which is evidently founded on the assumption that the precious metals constitute the wealth of a country, has been proved to be completely fallacious, and it is now conceded on all hands that gold and silver are nothing but commodities, whose exportation or importation it is necessary neither to prevent nor encourage by any legislative enactments. But the theory of the balance of trade is not erroneous merely from the false notions which its advocates entertain with respect to money: it proceeds on radically mistaken views as to the nature of commerce. For it will be found that, so far from an excess of exports

BALANCE OF A WATCH

over imports being any criterion of an advantageous commerce, it is directly the reverse since, were the value of the exports greater than the value of the imports, merchants would lose on every transaction with foreigners, and the trade with them would be speedily abandoned. For a succinct statement and exposition of the errors which were till lately generally prevalent upon this subject, see M'Culloch's *Commercial Dictionary*.

Balance of a Watch. That part of the machine which, by its inertia, regulates the beat and produces equable motion. It is formed of a wheel or ring, having its weight principally accumulated in its rim, and connected with a spiral spring in such a manner that when drawn aside from the position of rest it acquires an oscillatory motion from the alternate contraction and expansion of the spring. The balance answers the same purpose in watchwork as the pendulum in clockwork, and is affected in a similar manner by variations of temperature. Supposing the length of the spring to remain constant, the time of vibration is directly proportional to the distance of the centre of gyration from the axis of the balance; consequently the duration of the vibration is increased by heat and diminished by cold. To remedy this inconvenience, various contrivances have been applied; but that which is most generally adopted is the *expansion or compensation balance*, the principle of which depends on the unequal expansion of two different metals. It may be constructed in the following manner.

The rim consists of two laminae, the inner of steel and the outer of brass, united by fusion. After being turned to the proper size, the rim is cut in three places, A, B, and C; and one end of each of the parts thus formed being fixed to an arm of the balance, the other is left at liberty to move inwards or outwards according to the variation of the relative lengths of the two metals. D, E, F, are three equal weights placed near the free ends, and which, when adjusted at the proper distances, are fixed in their places by means of screws. Three heavy-headed screws, G, H, I, enter the arms of the balance, and serve to adjust its centre of gravity to the axis of vibration, and also to increase or diminish the mean rate of motion. Now, suppose the balance to receive an increase of temperature, this will tend to lengthen the arms, and consequently to throw the centre of gyration further from the axis, and thereby diminish the velocity of vibration; but as the brass expands more than the steel, the compound bars will at the same time be bent inwards, and the weights D, E, F thereby thrown nearer the axis, by which the velocity will be increased. When the temperature is diminished, the arms are shortened; but the weights are now thrown to a greater distance from the axis by reason of the contraction of the

BALDACHINO

brass being greater than that of the steel, and the consequent tendency of the compound bars to assume a less curved form. It is obvious that in so small a machine the adjustment of the parts to procure exact compensation is a matter of great nicety, and requiring much practical skill.

Balaninus (Lat.). In Entomology, the name applied by Germar to the subgenus of Weevils (*Curculionida*), of which the nut grub or nut weevil (*Balaninus nucum*) is a species. In the perfect insect the rostrum or borer is nearly as long as the body. It is by means of this instrument that the parent weevil drills a hole through the soft shell of the immature filbert, into which she introduces a single brown egg; this is hatched in about a fortnight, and by the time the nut is full ripe, the grub has attained its full growth; it then proceeds to bore a hole with its jaws through the shell, and emerges from the cavity of the nut; falling to the ground it burrows into the earth, and there remains during the winter, changing to the proper state, and appearing as a perfect insect in August.

Balanites (Lat. *balanus, an acorn*). In Zoology, acorn-barnacles; an order of Cirripeds, comprehending those which have a shelly tube, adherent by its base to foreign substances, and closed at its apex by four opercular valves.

Balanophoraceæ (*Balanophora*, one of the genera). A natural order of Rhizantha found mostly in hot climates, and consisting of fungus-like parasitical plants, with small monocious flowers, collected in dense heads arranged upon fleshy receptacles.

Balas Ruby. The name given by lapidaries to the rose-red varieties of Spinel.

Balausta (Gr. *Balaustion*, the wild pomegranate flower). In Botany, a kind of fruit having a leathery rind, a superior calyx, and several cells irregularly disposed, with many drupaceous seeds in each, as in the pomegranate.

Balcony (Ital. *balcone*). In Architecture, a projection from the external or internal wall of a house, borne by columns or consoles, usually placed before windows or openings. Balconies sometimes form a kind of string, and are continued from end to end of the building.

Baldachino (Ital. *a canopy*). In Architecture, a species of canopy over the principal altar of a church similar to that at St. Peter's, where it is supported by columns; or that of St. Sulpice at Paris, where it is suspended from above. It succeeded to the ancient *ciborium* [see that word], which was a cupola supported on four columns, still to be seen at many of the altars in Rome. Bernini may claim the merit of its invention. The height of that which he erected in St. Peter's is 128 feet, and being entirely of bronze weighs near 90 tons. It was built by order of the Pope Barberini, from the robbery of the roof of the Pantheon, and occasioned the bitter sarcasm—'Quod non fecerunt Barbari, fecerunt Barberini.'

BALDR

Baldr or Balder. [RUSTEM.]

Baldric (Low Lat. *balldrellus*). A girdle used by the warriors of feudal times; it was often splendidly ornamented.

Baldwin's Phosphorus. Fused nitrate of lime, which, after having been exposed to light, appears luminous in a dark place.

Baleario Crane. [CRANE.]

Baleen (Fr. *baleine*). The term for whale-bone in common use among whale-fishers.

Ball. Literally, anything made in a globular form. The word signifies also at once a well-known *divertissement*, and a game familiar in Europe and America. Ball-playing was a favourite amusement among the ancients, who practised it in various ways. They had their hand-ball (*pila trigonalis*), played by three persons standing in the form of a triangle, their foot-ball (*Follis*), and some other kinds not used by the moderns. Every complete gymnasium had its *Sphæristærium*, or place set apart for the game, with a master specially for teaching it, as long practice and great skill were necessary for it. In the middle ages there were houses appropriated to ball-playing; and in Italy there are still public places where this amusement is practised, and great dexterity displayed.

BALL. In the art Military, any round substance of iron or lead discharged from fire-arms, as cannon or musket balls. When artillery was first invented, cannon balls were rudely cut from blocks of stone; they are now made mostly of cast iron, and musket balls of lead. From the increasing use of rifled guns and rifled small arms, round projectiles are being superseded to a great extent, though they have still many advocates, who prefer them to elongated projectiles against armour plates.

Ballad (Ital. *ballata*, Fr. *ballade*). A species of narrative poetry, founded either on history or fiction, displaying the condition and the habits, the tastes and the sentiments of the various nations among whom it is found. The term ballad is very indefinite in its general acceptation, including classes of composition wholly different in themselves, of which the only common characteristics are brevity of metre and simplicity and perspicuity of style. While some authors have assigned to the ballad an Arabian, some an Armorian origin, and others have claimed this distinction for the Normans and Provençals, Percy, Bouterweck, and Schlegel concur in awarding to it a Teutonic descent. It is, however, agreed that the Scandinavian nations delighted at a very early period to celebrate in song the deeds of heroes, lovers, knights, &c.; and the three great divisions of the Teutonic poetry of the middle ages—the stories of the Nibelungen, those of Charlemagne (particularly such as relate to his wars against the Arabians and the battle of Roncesvalles), and the tales of King Arthur's Round Table, consist of what at a later period were called Ballads. Though the name Ballad is Italian, the spirit of chivalry

BALLAST

had at no period during the middle ages much dominion or influence on the other side of the Alps: a circumstance which sufficiently accounts for the meagreness of the Italians in this department of poetry. The French too never attained any perfection in the ballad, as their fabliaux, legends, &c. soon degenerated into long prose romances, which were quite destitute of the spirit of the ancient minstrelsy. The Spaniards, on the other hand, are rich in ballads of a highly chivalrous character. These, however, along with some Portuguese ballads which bear clear marks of a Spanish origin, may with more propriety be classified under the denomination of Romantic Poetry. Among the Welsh even so early as the twelfth century, music and this species of poetry seem to have attained a high degree of excellence; but of all the species of ballad, the Irish, among other characteristics, appears to be pre-eminently fitted for adaptation to music, as is witnessed in the universally admired *National Melodies* of Thomas Moore. While there is much difference of opinion among the learned as to the nature and requisites of the ballad, it is admitted on all sides that England and Scotland possess a collection of ballads superior to those of every other nation. The home of the English and Scottish ballads is either in the north of England, or in the southern counties of Scotland, as there the influence of the Normans was less than in the south of England. To the proximity, also, of those parts of the two countries where the ballad was cultivated, and the small circle which they embraced, may be attributed the difficulty that exists in assigning to each country its proper share in the collection of ballads. In modern times, if we except the romantic legends of Sir Walter Scott (which can scarcely be denominated ballads), the Germans have cultivated this species of poetry with more success than any other nation; and they can boast of Schiller, Goethe, and Bürger, not only as distinguished poets, but as the revivers of that chivalrous spirit which formed the grand characteristic of our British ancestors. For remarks on the Ballad, see Aikin, *History of Song*; Warton, *History of English Poetry*; Burney, *History of Music*; Motherwell, *Ancient and Modern Minstrelsy*; Jones, *Musical and Poetical Relics*; Schlegel, *Kritische Schriften* (article on Bürger); Sir W. Scott, *Minstrelsy of the Scottish Border*; Bishop Percy, *Reliques of Ancient English Poetry*.

Ballast (a word of uncertain derivation). Is a mass of weighty material placed in the bottom of a ship or vessel, to give her *stiffness*; that is, to increase her tendency to return to the upright position when inclined or *heeled over* by the force of the wind or other cause. Ballast consists of shingle (the coarse gravel of the sea-beach), stones, &c. In the Royal Navy iron ballast alone is used, in pigs of nearly 3 cwt. This has the advantage of lying in small compass; but in consequence of its great weight it tends to give excess of stability, which renders the vessel *uncasy* from the

suddenness of the motion: this defect is remedied by *winging up* the ballast, whereby its centre of gravity is raised. For the like reason, in stowing the ballast it is tapered to a point at the fore and aft extremities. Iron ballast, from its greater cleanliness, is more healthy for the crew than that of other materials. When a ship has no other loading, she is said to be *in ballast*.

The quantity of ballast and the mode of its stowage differ greatly in different vessels; and the connection between the motions of a ship and her stowage has not yet been analysed sufficiently to lead to the discovery of direct rules on these important points.

Ballet (Fr.). A theatrical representation of actions, characters, sentiments, and passions, by means of mimic movements and dances, accompanied by music. The ballet is divided into three kinds—historical, mythological, and allegorical; and consists of three parts—the entry, the figure, and the retreat. (Noverre, *Lettres sur les Arts imitateurs, et sur la Danse (à particulier)*.) The chief merit of the ballet lies in an ingenious adaptation of music to the sentiments of the mind as developed in the dance, and in its power of representing every variety of human conduct and emotion, whether of a tragic or comic nature. The art of dancing to music, called *ὄρχησις*, was carried to wonderful perfection by the Greeks: but the Latin Pantomimi corresponded much more closely to the ballet-dancers of modern times. It is generally believed that Baltazarini, director of music to the Princess Catherine de Medicis, first gave its present form to the regular ballet, and that after a considerable interval it was introduced into France, and thence into Germany and England.

Ballista or **Ballista** (Lat.). A Military engine, used by the ancients for throwing stones, darts, arrows, &c. The Ballista is sometimes confounded with the Catapulta; but a distinction is made by Polybius, who confines the latter term to those machines which throw stones only. The particular mechanism of these engines is not very certainly understood. According to Vitruvius they were made in divers manners; but the principle of all seems to have been the same. A beam of wood or plate of metal is firmly fixed at one extremity, while the other is drawn back by means of cords and pulleys; and being suddenly set free, the elastic force with which it seeks to recover itself propels the missiles.

Ballistic Pendulum. An instrument invented by Benjamin Robins, and first described by him in his Tracts published in 1765. It is used to determine the velocity of projectiles fired from cannon and small arms. The original instrument consisted of an iron bar, to one end of which was fixed a block of wood, the other end being attached to a horizontal bar free to move in sockets, so that the block on being struck swung together with the bar as a pendulum. A ribbon attached to the bottom of the pendulum showed, by the

portion of it drawn through an orifice in the fixed framework, the length of the arc through which the pendulum moved.

The use of the pendulum depends upon the dynamical fact that if a body of small mass impinge with great velocity on a much larger body at rest, and the two bodies after impact move on together with a velocity which can be easily measured, the masses of the two bodies being given, the whole momentum after impact is known; and as this is the momentum of the smaller body before impact, the velocity with which it struck the larger body can be determined.

Robins' pendulum was improved by Hutton and Gregory, and later by MM. Piobert and Morin in France, and Major Mordecai in America. As now used, the block consists of a cast-iron case, filled with barrels or bags containing sand. It is suspended by firmly secured wrought-iron bars to a horizontal shaft which has knife edges working in Vs, so that the pendulum may vibrate freely. The arc through which the pendulum vibrates on being struck is measured on a copper arc by an index carrying a vernier. This being ascertained, the following points must be known in order to calculate the velocity of the ball on striking:—

1. The respective weights of the ball and pendulum.
2. The distance of the centres of oscillation or percussion from the axis of suspension.
3. The distance of the centre of gravity from the axis of suspension.
4. The angular velocity of the pendulum after impact.

The ballistic pendulum has been lately used in conjunction with the gun pendulum [GUN PENDULUM], but is now seldom employed, the velocities of shot being more easily and correctly ascertained by Navez' electro-ballistic apparatus. [ELECTRO-BALLISTIC APPARATUS.]

Ballium. In the Architecture of the middle ages, the open space or court of a fortified castle. This has acquired in English the appellation Bailey: thus St. Peter's in the Bailey at Oxford, and the Old Bailey in London, are so named from their connection with the sites of castles.

Balloon (Fr. *ballon, a little ball*). The name of a machine, which, consisting of an envelope containing a gas specifically lighter than common air, rises into the atmosphere with a greater or less degree of ascensional force. A car, supported by a network which extends over the balloon, supports the aeronaut; and a valve, usually placed at the top, to which a string is attached reaching to the car, gives him the power of allowing the gas to escape, and of descending at pleasure.

During the dark ages, and for some time after the revival of science, numerous projects were entertained for navigating the air; but it is only in very recent times, since 1783, that any of them have been realised. The first idea was to employ some mechanical contrivance

BALLOON

resembling the wings of birds; but Borelli demonstrated that all attempts on the part of man to fly must necessarily fail, from the utter disproportion of his muscular power to the force that would be necessary to give impulsion to wings of such enormous magnitude as would be required to sustain his weight in the air.

The principle by which a balloon rises in the atmosphere is exactly the same as that which causes the ascent of a cork from the bottom of a vessel filled with water. The weight of the volume of air which it displaces must exceed the weight of the balloon and all that it carries with it.

The height to which a balloon will rise is determined from the law according to which the density of the atmospheric strata diminishes as the distance from the earth is increased. The buoyant force diminishes with the density; and when it is reduced to a quantity only equal to the weight of the balloon and its appendages, no further ascension can take place. Another circumstance also confines the possible elevation within moderate limits. As the pressure of the external air is diminished, the expansive force of the confined gas becomes greater, and would ultimately overcome the resistance of any material of which a balloon can be made. A balloon quite filled at the surface of the earth would inevitably be torn to shreds at the height of a few miles in the atmosphere, unless a portion of the gas were allowed to escape. For this purpose the balloon is furnished with a safety valve, which can be opened and shut at pleasure; but to prevent unnecessary escape of gas, it ought to be made of such a size that it requires only to be partly filled.

When balloons first began to be constructed, it was expected that they would be found applicable to many important purposes. These expectations have been disappointed, chiefly because it has been found impossible to guide or control their course. The only power the aeronaut possesses over his balloon is to regulate its elevation within certain limits. In one or two instances they have been successfully used for military reconnaissance. The victory which Jourdan obtained over the Austrians at Fleurus, in 1794, was ascribed to the knowledge obtained of the enemy's movements by means of a balloon. A very interesting ascent was made by Biot and Gay Lussac, in August 1804, and by Gay Lussac alone in September of the same year, with a view to make meteorological observations in the upper strata of the atmosphere. In the first voyage, the two philosophers, at an elevation of between 9,500 and 13,000 English feet, found the oscillations of the magnetic needle to be performed in the same time as at the surface of the earth. At 12,800 feet the thermometer, which stood at $63\frac{1}{2}^{\circ}$ at the Observatory, had sunk to 51° of Fahrenheit, being only a decrease of 1° for every thousand feet. The hygroscope indicated increased dryness in proportion to the elevation. In the second ascent, performed by

Gay Lussac alone, the variation of the compass at the height of 12,680 feet, was found to remain unaltered. At 18,000 feet the thermometer fell to the freezing point, and at 22,912 feet to 14° of Fahrenheit. Two flasks, which had been previously emptied of air, were opened and filled at an elevation exceeding 21,400 feet; and the air brought down from this region was found, on being analysed, to contain the same proportions of oxygen and nitrogen as at the surface. The utmost elevation which he reached was 23,040 feet, or four miles and a quarter above the level of the sea.

In the summer of 1862, Mr. Glaisher added much to our knowledge of the higher regions of the atmosphere in several ascents, undertaken at the suggestion of the British Association for the Advancement of Science, in an enormous balloon constructed and managed by Mr. Coxwell. The balloon was 55 feet in diameter and 69 feet in height, and was capable of holding 90,000 cubic feet of gas. During one of the ascents, at the height of two miles, the temperature fell to 32° , at three miles to 18° , at four miles to 8° , and at five miles to 2° below Fahrenheit's zero. At the latter height no dew was observed on Regnault's hygrometer when cooled to minus 30° . At nearly six miles, as indicated by the barometer ($9\frac{1}{2}$ inches), Mr. Glaisher became insensible. Mr. Coxwell also lost the use of his hands, but had sufficient strength and presence of mind to pull the valve-string with his teeth, thus allowing of an escape of gas and the descent of the balloon. The neck of the envelope was at this time surrounded with hoar-frost. An observation made by Mr. Coxwell while Mr. Glaisher was insensible, would indicate that the greatest altitude reached was six and a half miles, and the lowest temperature 12° below zero. Of six pigeons taken up, one was thrown out of the car at three miles: it simply extended its wings and dropped like a piece of paper; the second at four miles flew downwards tolerably well; the third at four and a half miles fell rather than flew; the fourth was thrown out while descending, it flew and alighted on the top of the balloon; the fifth died before the car reached the earth; and the sixth, thrown off the finger after the aeronauts had alighted, returned to the hand, but subsequently flew away. From this ascent it would seem that five miles from the earth is nearly the limit of human existence, and that increased information which might be obtained at greater elevations is not commensurate with increased risk. One of the most important results of Mr. Glaisher's ascents is the demonstration of the fallacy of the belief that the atmosphere decreases 1° Fahrenheit in temperature for every 300 feet ascended.

Excepting in these memorable ascents, little has been gained to science by the use of balloons; and from the total failure of every scheme that has been proposed for directing their course through the air, there is little reason to anticipate any great advantages from them to society.

BALLOT

Ballot (Fr. *ballotte*). A method of voting at elections, &c., by means of little balls, of different colours, which are put secretly into a box, and, when counted, disclose the result of the poll without any discovery by whom each vote is given. In their popular assemblies the Athenians generally voted by a show of hands; but the ballot was employed where secrecy was a matter of importance. In judicial proceedings it was always used; but there were three processes, admitting different degrees of secrecy. Secret voting was also the custom of the court of Areopagus. The same system of voting prevailed also at Carthage, and to this is attributed by Ray (*Travels through Germany and Italy*) the cause of the grandeur and independence of its inhabitants. At Rome, voting by word of mouth was the practice at elections and trials, secret voting by pebbles being confined to the enactment or repeal of laws. The Lex Tabellaria of Gabinus, B.C. 130, introduced the ballot into elections of magistrates. From this period, although the practice of bribery made rapid strides, every effort was made for its suppression by the enactment of penal statutes. Since the Christian era, the ballot was adopted at a very early period by the Maltese and the Venetians. At Venice, in particular, a most curious and intricate system of voting, consisting of ten ballutations, prevailed for the space of 1,300 years; and Postellus (in a work *De Magistratibus Atheniensium*) pointedly asserts that the abolition of this practice, combined with other causes, led to the decline of this once flourishing state. Another author, after an elaborate dissertation on the advantages of the Venetian ballot, sums up his account of an election of which he had been an eyewitness in the following words: 'All was easily performed in a short time, without tumult, without noise, without animosities, and the most deserving always elected.' In our own times, as is well known, the system of voting by ballot in the election of representatives, magistrates, &c. is adopted in France and America; and, among ourselves, in cases of application for admission into private clubs and societies. Of all subjects for controversy, perhaps there is none which has excited the attention of all political parties so vividly, and furnished so large an arena for the display of argumentative skill, as the ballot.

The advocates of the ballot, on whom the onus probandi naturally rests, assume as an axiom that the great body of the electors are dependent, and consequently in an unfit condition to give a free and unbiassed vote, while the ballot, it is maintained, would not only place the elector on a footing of independence, but would remove all inducement to bribery, as no candidate would offer a bribe when the elector is at liberty to deceive him by giving a secret vote; in a word, it would annihilate the two species of corrupt influence by which electors are liable to be swayed—the influence of threats, and the influence of bribes. The

BALSA

opponents of the ballot, on the other hand, maintain that, even under the ballot, the canvassing of constituents by candidates would still be practised; in which case, the ballot would prove serviceable only to the dishonest elector, who promises his suffrage to one candidate and votes for another. It is further urged that even were secrecy practicable (vide Burke's *Reflections*, p. 370), it would not be desirable; for, as every elector holds his vote for the benefit of the community at large, he is bound to show by an open vote his opinion of the fitness of the candidate for his suffrage, while a secret vote is eminently calculated to lower the standard of political and moral principle, inasmuch as it removes from a public act that responsibility from which no public act ought to be exempted. And lastly, it is urged that the argument derived from the practice of France and America can have but little weight, unless it can at the same time be demonstrated that the condition of these countries in other respects is precisely analogous to that of our own. The recent history of both these countries has had a sensible effect in increasing the dislike generally felt in England for this system of voting. But, whatever may be the value of the arguments on either side, it is clear that both as Rome and Athens the people either stipulated for the adoption of the ballot in the original framing of the moral constitutions, or, at they ascertained the nature of the rights, insisted on its introduction, from some fancied security it afforded them in the exercise of their privileges. For some apposite remarks on the ballot, see Montesquieu, *Esprit des Loix*, ii. cap. 20; Sydney Smith, *Works*, vol. iii. 'The Ballot.'

Balneum. Was the Latin term for a bath, or the bathing vessel itself; and it was afterwards applied to a private bathing chamber. Pliny, and the more modern writers, however, use the word balneum in the sense of a private bath, and balneæ as a public bath; and they use indifferently to express the latter description of baths the terms balneæ and thermæ. It would appear from this that the public baths of the Romans were all of them supplied with warm water, and were what we should call warm baths.

Balsa (Span.). A species of float or raft, chiefly used on the coasts of South America, for landing goods through a heavy surf. The balsa is formed of two seal skins sown up so as to form two large bags, which are covered with pitch to render them perfectly air-tight, and secured by ligatures. The bags or bladders thus prepared are inflated with air passed through a flexible tube, which is left of sufficient length to reach the mouth of the conductor, who is thus enabled to replenish them with air, should any have escaped. The two bags are fastened together at one end, which forms the prow of the vessel, the other ends being kept about four feet apart by means of a small plank; and the raft is completed with small sticks covered over with matting, having thus

BALSAMACEÆ

the shape of a wedge or triangle. It is propelled by a double-bladed paddle, and the conductor, on approaching the shore, contrives to keep the balsa on the top of the highest wave till it is thrown on the beach to the greatest extent the surf reaches, where it is immediately secured. The balsa will carry three passengers besides the person who conducts it, and by this means cargoes are landed from merchant vessels where the violence of the surf prevents ordinary boats from passing; through it without great danger. Floats of a still ruder kind, usually formed of the hides of bullocks simply stretched on a frame, are used for crossing rivers in South America, and go by the name of balsa.

Balsamaceæ. A natural order of imperfect exogenous balsamiferous trees, related to the *Platanaceæ*, now called *Altingiaceæ*. A species of the only genus, *Liquidambar*, yields the fragrant product called storax.

Balsaminaceæ (*Balsamina*, one of the genera). A natural order of polypetalous Exogens, allied to *Geraniaceæ*. They have irregular flowers, with a spur to one of the sepals; and are chiefly annual-stemmed plants, with succulent foliage and showy flowers. The common *Impatiens noli-tangere*, or Touch-me-not, is a species of this order.

Balsamodendron (Gr. *βάλσαμον*, and *δένδρον*, a tree). A genus of shrubby plants found in India, Arabia, and Abyssinia, belonging to the order *Amyridaceæ*. They have spiny branches, scanty pinnated leaves, and small axillary flowers succeeded by small oval drupe-like fruits. *B. Myrrha* is the reputed source of the gum-resin called myrrh; *B. gileadense* and *B. Opobalsamum* yield Balm of Gilead; *B. africana* yields African Bellium; and *B. Roxburghii*, Indian Bellium; and other species furnish gum-resins of similar character.

Balsams (Gr. *βάλσαμον*). Exudations from certain plants, which are liquid or soft solid, and consist of a substance resembling a resin either combined with benzoic acid or with an essential oil, or both.

Balteus (Lat.). The wide step in theatres and amphitheatres, which afforded a passage round them without disturbing the seated spectators; nobody sat upon it, but it served as a landing, or resting-place. In the Greek and the Roman theatres every eighth step was a balteus; and Vitruvius gives the rules for constructing it in the third chapter of his fifth book. The same term is used by that author to denote the strap which seems to bind the rushion of the Ionic capital.

Baltic Sea. This long narrow inland sea, of extremely irregular form, deeply indenting almost the whole of Northern Europe, receives by some 250 streams the drainage of more than a fifth part of the whole continent. It is rarely more than forty or fifty fathoms deep. It communicates with the Atlantic by a single channel, and owing to the number of rivers entering it is much less salt than the ocean. It occupies in all 135,000 square miles, its total length is

BAMBOO

1,000 miles, and its mean breadth less than 150 miles. Beyond it the Gulf of Finland runs for 300 miles with a width of from 50 to 80 miles, and connects it with a chain of lakes reaching almost to the White Sea.

The Baltic is the Mediterranean of the north. It has scarcely a perceptible tide, but its waters are subject to singular oscillations, affecting its level to the extent of three feet or more. For five months of the year its waters are frozen.

The navigation of the Baltic is difficult and dangerous, and is of course interrupted during winter. The entrance is complicated, being almost closed by the peninsula of Jutland and the Danish islands between Jutland and Sweden. The whole of the waters of the inland sea are thus rendered independent of the ocean.

Baltimore. A pseudomorphous form of Serpentine after Asbestos, to which it bears considerable resemblance. It occurs in opaque greyish-green fibres with a silky lustre, at Baltimore in North America; and, also, at Killin in Perthshire.

Baluster (Fr. balustre, Span. balaustre, possibly from *bara* or *vara*, a rod). A species of small short column used between piers on the upper parts of buildings, under windows, in balconies, &c. It is quite of modern introduction, that is to say, it dates shortly after the Renaissance. The form of the most ancient balustrade that is to be met with in Florence and in other parts of Italy, is that of a column, a puerility which has even in these days found admission into some of what are called Grecian buildings in the metropolis. Blondel and Chambers give rules for proportioning baluster in cases where it is used in conjunction with the orders. In practice the term baluster is also made to signify the dwarf railing which protects a staircase, and thence it is applied to small cast-iron columns, or panels, of any conceivable form, the term being applied with reference to the use, not to the nature of the decoration. There are swan-necked balusters, panelled balusters, &c.

Balustrade. A parapet or fence formed with balusters. This term is sometimes applied to cast-iron panelling.

Bambocciate. A name applied to pictures of low or vulgar life, such as the Dutch have loved to paint, and such as were termed by the Greeks *Rhyparography*, or literally dirt-painting. The term Bambocciate is supposed to be derived from the nickname of Bamboccio given by the Italians to Pieter Laer, the first of the characteristically Dutch painters who distinguished themselves in Rome.

Bamboo. An Asiatic genus of arboreous grasses, called *Bambusa* by botanists. They have hollow jointed stems of a hard woody texture, and externally coated with silex, and sometimes they secrete the same substance in the hollows of their stems, when it is called tabasheer. Bamboos grow with great rapidity, and their shoots are cut when young, and boiled like asparagus. They vary in size, according to the species, from 6 feet to 150 feet

BAMBUSIDÆ

in height. When small, they form walking sticks and handles to umbrellas and parasols; when sufficiently large, they are used for the framework of Indian cottages, bedsteads, floors, and a variety of domestic purposes. If split into slips they form bow-strings, and sometimes the arrows discharged from the blow-tubes of the Malays. A few species inhabit the tropical parts of America.

Bambusidæ. A section of the natural order of Grasses, comprehending the Bamboo as its type.

Bamlite. A mineral with the structure and appearance of some kinds of Kyanite, occurring at Bamle and Brakka in Norway, in gneiss.

Ban, Bann. The public notices of marriage given in church, derived from the civil law, are called Banns of Marriage. According to the law of England, the banns must be published three successive Sundays; and if the marriage be not performed within three months from the last publication, the same process must be repeated. Bishops have the power of appointing surrogates, who may grant a faculty or license to parties applying to be married without banns. But this license may only be given under certain conditions, and upon good caution and security taken, such as to supersede the necessity of public proclamation. The word 'Ban' bears a variety of significations in the Teutonic jurisprudence and usages, but all apparently connected with the original meaning of 'to proclaim or give public notice.' Hence,

1. The proclamation against an outlaw: e.g. the ban of the German Empire, equivalent to ecclesiastical excommunication or declaration of outlawry; whence the words banish, bandits, banditti, and to 'ban' or curse; in German, bannen, verbanen. 2. The national army of a Teutonic people levied by proclamation: hence the French 'lever le ban et l'arrière ban' (the latter word being a corruption of *heribannum*, from *heer*, an army). The French ban and arrière ban was levied for the last time in 1672, and commanded by Turenne, but behaved so ill that this feudal armament was thenceforth discontinued. 3. In the Slavonic tongues ban means master: and the lords of some of the frontier provinces of Turkey were so styled; hence the *bannat* or lordship of Temeswar, now belonging to Austria. The viceroy or governor of Croatia is styled the Ban, and enjoys extraordinary privileges.

Banana. A tall herbaceous endogenous plant, the *Musa sapientum* of botanists, having broad convex leaves with fine oblique veins, and growing in a tuft from the top of a stem formed by the union of the broad bases of the leaves. The fruit, which ripens in succession, grows in large clusters weighing many pounds, and is of the same nature as the plantain. It is a native of the West Indies, where it contributes essentially to the food of the better classes.

Banehus. A Fabrician genus of Hymenopterous insects, of the tribe *Pimplina*, and family *Ichneumonidae*; characterised by long threadlike antenna, abdomen compressed at

BANDOLEER

the extremity, ovipositor not extended. Of this genus there are five British species, which, like the rest of the family, are parasitic in the larva state, feeding on the bodies of other insects.

Banco. In Commerce, a word of Italian origin, signifying a bank, and commonly employed to describe the bank of Venice. Banco is also used to distinguish banco money from current money at Hamburg, &c. [EXCHANGER.]

BANCO. In Law, superior courts of common law are said to sit in banco during term, the judges occupying the bench of their respective courts. [COURTS OF LAW.]

Band (Fr. bande). In Architecture, a term used to denote what is generally called a face or fascia. To speak correctly, it signifies a flat, low, square, profiled member, without respect to its place. That member in a cornice on which modillions or dentals are cut is called the modillion band in the former, and the dental band in the latter case.

BAND. In Machinery, a band is a contrivance for transmitting power with less noise and friction than attends the use of toothed gearing, and the bands used are made either of leather or gut, according to the position and usage of the engine. The employment of bands also gives the advantage of admitting the use of fast and loose pulleys, or those which are able to turn with the machinery, or without it.

BAND, MILITARY. In Music. A military band differs from a concert orchestra in the omission of the stringed instruments; it consists of wood and brass wind instruments only, with the addition of certain instruments of percussion, as drums and cymbals. The clarionets supply the place of violins, and the brass wind instruments are much more developed than in the concert orchestra. Some military bands dispense with wood instruments altogether, and are then called brass bands.

Bandanna. A style of calico-printing in which white spots are produced upon a red ground. The term is of Indian origin, and the art has been extensively adopted and improved upon in this country. (See a detailed account of Messrs. Monteith's manufactory at Glasgow, in Brande's *Quarterly Journal of Science and the Arts*, June 1823, and in Ure's *Dictionary of Arts*, &c.)

Banded. A term answering to the Lat. *fasciatus*, and denoting any body which is striated across with coloured bands.

Banditti (Ital.). Persons declared to be banished, exiled, or outlawed. At the present time, bandit and robber are nearly synonymous terms. The Italian bandits formed a peculiar class, and were frequently employed by the petty princes and nobles in executing their projects either of love or ambition. As late as the year 1820, they were frequently employed as escorts; and in their case the proverb 'Honour among thieves' was amply verified, for, on the payment of a stipulated sum, travellers might repose in them unlimited confidence.

Bandleer. In the sixteenth and seventeenth centuries, a leathern belt worn over the

BANIAN

shoulder or round the neck, to carry in small cases the made-up charges for the musket.

Banian (more properly *Bania*). A class among the Hindus, whose office or profession is trade and merchandize. In common language, the native cashier or man of business in the service of a European is called in Bengal a Banian. In the West of India, Hindu traders in general are so styled.

Banishment. [BAN.] Expulsion from any country, province or town, by the judgment of some court or competent authority. Banishment as a species of punishment has been practised by all governments, both ancient and modern. Among the Athenians two kinds of banishment were in use: *φύγη*, which involved confiscation of property, and was inflicted only upon those convicted of certain crimes; and *ostracism*, by which persons were banished, if a number of citizens, in no case less than 6,000, declared that their banishment was needed for the good of the city. The Romans made use of three kinds—*relegatio*, *exilium*, and *deportatio*—which involved various grades of punishment; the last, however, being the most severe, as it subjected the delinquent to the confiscation of his property and the loss of his rights as a Roman citizen. The second was introduced by the emperor Augustus, and formed the kind of banishment to which, among others, Ovid was condemned. In France, deportation is classed in the third degree of infamous punishments, and is synonymous with civil death. As a criminal punishment, banishment was unknown to the ancient unwritten law of England, although voluntary exile was often adopted to evade legal prosecution. It was towards the close of Queen Elizabeth's reign that the first statute was enacted which condemned persons convicted of certain offences to leave the town or village where they lived, but it was at a much later period that the punishment of *transportation* [which see] was legalised by parliamentary statute. In Germany, many instances have recently occurred in which persons convicted of treasonable practices have had their sentences commuted into perpetual banishment; and in the German universities this punishment, inflicted on those who have grossly broken the academical laws, involves the forfeiture of all right to enter upon a professional career.

Banisteriaceæ (*Banisteria*, one of the genera). That division of malpighiaceæ plants in which the fruit is samaroid, not baccate, and analogous to what is found in *Aceraceæ*.

Bank. In Commerce, an establishment for the custody and issue of money. The individual who manages a bank, or who carries on the business of banking, is called a banker.

Banks are of various kinds; some confining themselves entirely to the custody and issue of the money deposited in their hands by their customers, while others issue notes or paper money of their own. They are sometimes conducted by private individuals, and sometimes by companies consisting of an indefinite number of persons.

BANK

Utility of Banks.—Although the precious metals are, in many respects, admirably fitted to serve as a medium of exchange [MONEY], they have two very serious drawbacks, their cost, and the difficulty and expense of carrying them from place to place. If the currency of Great Britain consisted only of gold, it would amount to perhaps two hundred millions of sovereigns; and the expense attending such a currency, including the wear and tear and loss of coins, could not be reckoned at less than 6 per cent., or 12,000,000*l.* a year. The weight of 1,000 sovereigns exceeds 21 lbs. troy; so that were there nothing but coins in circulation, the conveyance of large sums from place to place to discharge accounts would be a very laborious process, and even small sums could not be conveyed without considerable difficulty; hence it is that most commercial and highly civilised nations have endeavoured to fabricate a portion of their money of less costly and heavy materials, and have resorted to various devices for economising the use of coin. Of the substitutes for coin hitherto suggested, paper is, in all respects, the most eligible. Instead of discharging their debts by a payment of the precious metals, individuals, on whose solvency the public may rely, pay them by giving a bill or draft for the sum, payable in coin at sight, or at so many days after date; and as this bill or draft passes currently from hand to hand as cash, it performs all the functions of coin, while it saves its expense to the public. A sense of the advantages that might be derived from the circulation of such bills or drafts led to the institution of banks for their regular issue.

By a bank of this description, or a bank of circulation, is meant an establishment founded by one or more individuals, known or believed to be possessed of large property, for the accommodation of the public with loans. A banker, on being applied to for a loan, does not make the advance in gold or silver or other valuable material, but enters into an engagement, binding him to pay the sums specified on demand, or at some specified period. When a bank is in good credit, its notes are deemed by the public equivalent to a corresponding amount of gold or silver; and being freely accepted in payment of debts of all sorts, and easily carried about or conveyed by post, they are even more useful than an equal sum in coin. The borrowers, therefore, do not scruple to pay the same interest for the loan of a promissory note of 100*l.* or 1,000*l.* that they would do for the loan of a hundred or a thousand sovereigns. But the note costs the issuer comparatively little. He, in fact, deals in credit, or in obligations to pay, and not in real values; his profits consisting in the excess of interest derived from the notes or obligations he has issued over and above the interest of the cash or unproductive stock which he is obliged to keep in his coffers to meet the demands of the public for payment of his notes, and the expenses of his establishment.

BANK

Besides this sort of bank, there are also banks of deposit, or banks for keeping the money of individuals. A merchant, or other person using a bank of this sort, makes all his considerable payments by drafts upon his bankers and sends all the bills due to him to them to be presented, and noted, if not duly paid. By this means he saves the trouble and expense of keeping a quantity of unemployed money at home, of receiving coins or notes that are not genuine, and of making any mistakes with respect to the presentation of due bills; and in consequence of the saving of money that is thus effected, a much less quantity serves for the demand of the public.

If a bank of circulation, or an establishment for the issue of notes, fall into discredit, its notes must obviously cease to circulate. Unless when guaranteed by government, or made legal tender, no one ever takes promissory notes, except on the supposition that they will be paid when presented or when due, and that they are substantially equivalent to cash. The moment any suspicion (whether well or ill founded is so far of little consequence) arises that the issuers of notes are unable to meet their obligations, there is a run upon them for payment, and their notes are rejected by everyone.

All banks of circulation are necessarily almost at the same time banks of deposit; but there are in all civilised and commercial countries a good many of the latter class of banks only. Banks of deposit derive their profit either from their paying no interest on the sums deposited in their hands, as was the case with most of the London banks; or from their paying a less rate of interest on deposits than that for which they lend them to the public, as is the case with the Scotch banks.

English Banks.—Banking establishments for the issue of notes, and for taking care of other people's money, have existed in this country since the latter part of the seventeenth century. The Bank of England was founded in 1694, and has long been the greatest bank of circulation and deposit in the world. It grew out of a loan of 1,200,000*l.* for the public service, for which (such was the low state of public credit at the time) the subscribers were to receive 8 per cent. interest, with 4,000*l.* a year as the expense of management, and be incorporated into a banking company, denominated the Governor and Company of the Bank of England. The charter was granted for ten years; and it has since been prolonged by various renewals till the 1st August 1856, and from that date subject to a year's notice. The loans made by the Bank to government were gradually increased, till in 1800 they amounted to 14,686,800*l.* But at the renewal of the charter in 1833, a fourth part of the standing debt due to the Bank was paid off, making the sum

ment, exclusive of advances on account of dead weight and other public securities, 11,016,100*l.*

From its foundation the Bank has enjoyed

several peculiar privileges. The principal of these was conferred upon it in 1708, by an Act which prohibited any company from being established for the issue of notes payable on demand in England and Wales with more than *six* partners. This restriction continued till 1826, when it was abolished, in so far as respects all places more than sixty-five miles distant from London. Within that distance it still prevails; but by a late Act private banks may now have ten partners.

The Bank of England is, and always has been, the government bank, transacting for it all the banking business of the nation, receiving the produce of the taxes, loans, &c.; and paying the interest of the public debt, the drafts of the Treasury and other public departments, transferring stock, &c. For this the Bank receives, exclusive of the use of the balances of the public money in her hands, about 95,000*l.* a year.

In consequence of its employment by the government, of the restriction confining the number of partners in other banks to *ten*, and of its great capital and credit, Bank of England notes have always been held in the highest estimation; and no bank for the issue of promissory notes payable on demand has been established in or near London. In the provinces, however, numerous *private* banks (that is, banks with not more than *ten* partners) of issue and deposit have always existed. In 1792, their number is supposed to have exceeded 350. Many were destroyed by the convulsion of that year; but subsequently to 1800 they began rapidly to increase. In 1809, they amounted to 782; and in 1814, when most numerous, to 940. Since the abolition of the restriction on the number of partners, in 1826, many banks have been established; some with very large bodies of proprietors. Except in the case of the Bank of England, all the holders of stock in the other English banks, unless expressly constituted on the *limited liability* principle, granted by the Act 25 & 26 Vict. c. 89, passed in August 1862, are liable not merely for the amount of their share in the capital stock of the company, but for its whole debts, whatever may be their amount. All notes are made payable on demand; and since 1826 no notes for less than 5*l.* have been allowed to circulate.

From the first establishment of the Bank of England, down to 1797, she always paid her notes regularly when presented. But in the course of 1796, and the early part of 1797, there was, owing to the prevalence of reports of invasion, a pretty severe run upon the Bank of England, and it was at length apprehended that she might be obliged to make a temporary stoppage. To avert a contingency of this sort, an order in council was issued in February, 1797, authorising the Bank not to pay her notes in gold; and this order was subsequently confirmed by parliament, and prolonged till after the conclusion of a definitive treaty of peace.

Contrary to what might have been and was

BANK

anticipated by many, the order referred to did not stop the circulation of Bank of England notes, or diminish the confidence of the public in that establishment. The report of a committee of the House of Commons, published soon after the suspension, showed that the Bank was not merely possessed of the most ample funds to meet all her engagements, but that she had a surplus stock, after all demands upon her were deducted, of no less than 15,513,000*l*. This report, and the fact that Bank of England notes became practically legal tender, secured their circulation.

The obligation on the issuers of paper to pay their notes on demand is necessary, not only to give them circulation, but to prevent their being issued in excess. While the Bank of England was obliged to pay in specie, the value of her notes could not, and in point of fact did not, differ materially from that of gold. But in 1799, or 1800, after the check of cash payments was removed, they began to be depreciated, partly in consequence of their own over-issue, but far more through the over-issue of the paper of the country banks. The latter were multiplied to an unprecedented extent. It is of importance, too, to observe that previously to 1797 neither the Bank of England nor any of the country banks issued notes for less than 5*l*.; but both parties having commenced the issue of notes for 1*l*. in the course of that year, a new outlet was opened for the emission of paper that was particularly accessible to the country bankers. And such was the eagerness of the greater number of the latter to get their paper afloat, that individuals who could barely afford to buy stamps for bills frequently succeeded in getting the command of immense sums; and as they had nothing of their own to lose, boldly ventured on the most hazardous speculations. During the last half-dozen years of the war the depreciation of paper resulting from the circumstances now glanced at was such, that the ounce of standard gold, which should be worth only 3*l*. 17*s*. 10½*d*., was, in 1814, actually worth 5*l*. 4*s*., being a depreciation of 25½ per cent.

The difficulties which had been thrown during the latter years of the war in the way of importation from abroad, combined with deficient crops at home, caused an extraordinary rise in the price of corn. But no sooner had the northern ports been opened, in the autumn of 1814, than a large importation, accompanied by a heavy fall of prices, began to take place; which was still further increased after the general pacification in 1815. This fall proved ruinous to many farmers, who had been large borrowers from the country banks. In consequence of the losses arising from this and other causes that grew out of the altered situation of the country, a want of confidence was experienced; and the country banks being generally without the means of meeting any emergency, no fewer than 210 of these establishments stopped payment. There is, in fact, believed to have been, in 1814, 1815, and 1816, a greater destruction of bank paper in this

country, and a wider range of bankruptcy, than had ever previously taken place anywhere else, except perhaps in France at the breaking up of the Mississippi scheme. The contraction of the currency that had been thus violently brought about raised its value nearly to par, and paved the way for the Act of 1819, the 59 Geo. III. c. 78, commonly called 'Peel's Act,' from its being introduced by Sir Robert Peel, which provided for the return to cash payments by the Bank of England at the old standard. These were resumed in 1821.

Although the bankruptcy which overspread the country in 1814, 1815, and 1816, was mainly ascribable to the defective constitution of the country banks, and to the reckless and improvident manner in which they were managed, no steps were taken when the resumption of cash payments was decided upon in 1819 to obviate any one of these sources of mischief. The consequences were such as might have been anticipated. A peculiar combination of circumstances having conspired to produce an extraordinary rage for speculative undertakings in 1824 and 1825, the country bankers gave in to the infatuation, and made the most sudden and excessive additions to their advances. In consequence the currency became redundant; and this having occasioned a heavy drain for gold on the Bank of England, the latter was, in the end, obliged to contract her issues. The country banks, whose engagements had in many instances been carried to an extent quite incommensurate with their capital, began to give way the moment they experienced an increased difficulty of obtaining pecuniary accommodation in London; and so rapid and sweeping was the destruction, that in less than six weeks above seventy banking establishments were swept off, and a vacuum created in the currency that absorbed from eight to ten millions of additional issues by the Bank of England!

This catastrophe seems at length to have satisfied the parliament and people of England that the private banking system was weak and vicious, and that it was imperatively necessary it should be amended and strengthened. In this view the clause in the Act of 1708 already referred to, prohibiting any private bank from having more than six partners, was repealed; and the issue of notes for less than 5*l*. was also forbidden.

The last measure shut up one of the easiest channels through which the inferior order of country bankers used to get their paper into circulation, and was thus far advantageous. But many other channels are still open to them; and the fact that a third part of all the private banks existing in England and Wales in 1792 were destroyed during the revulsion of that year, though no notes for less than 5*l*. were then in circulation, shows how little the suppression of small notes can do to obviate the mischiefs complained of. Very important advantages were, however, expected to result from the other measure, or that repealing

BANK

the Act of 1708, and consequently allowing the formation of joint-stock banks, or banks with any number of partners. But these anticipations have been only partly fulfilled. There cannot, in truth, be a greater error than to suppose that because a bank has a considerable number of partners it will necessarily be either rich or well managed. It may be neither the one nor the other. A single individual may possess more wealth than a number of individuals associated together; and the chances are, that if he engage in banking, or any other business, it will be better managed than by a company. Under our present system, and indeed it is impossible to prevent it under any system, the partners in joint-stock, or in other banks, may be men of straw, or persons without property, and unable to fulfil their engagements. It is of the essence of a secure and well-established paper currency that the notes of which it consists should be of the exact value of the gold or silver they profess to represent, and that, consequently, they should be paid the moment they are presented.

Previously to 1833, the notes of the country banks were made payable in gold; but it was then enacted that they might be paid either in gold or Bank of England notes, at the option of the issuers. Bank of England notes are now, in fact, legal tender everywhere except at the Bank and her branches.

The dividends on Bank of England stock from 1767 to the present time have been—from 1767 to 1781, $5\frac{1}{2}$ per cent. per annum; from 1781 to 1788, 6 per cent.; from 1788 to 1807, 7 per cent.; from 1807 to 1823, 10 per cent.; and from 1823 to 1838, 8 per cent. In 1861 and 1862 they were 10 and $8\frac{1}{2}$ per cent. The dividends are exclusive of income tax, and of the sums occasionally advanced as *bonuses*; the latter amount, since 1799, to 3,783,780*l.* over and above an increase in the capital of the Bank in 1816, which amounted to 2,910,600*l.*

New System of 1844.—The defects previously noticed in our banking system were again fully developed in 1836 and 1837. It is needless now to enter upon any investigation of the circumstances which led to the over-trading of these years; but it was carried to a great extent both here and in the United States. In nothing, however, was this more strikingly evinced, than in the rapid increase of joint-stock banks; their number, which in 1834–35 had amounted in England and Wales to 65, having risen in 1835–36 to no fewer than 100! Many of these were banks of issue, and large additions were thus suddenly made to the volume of advances and transactions on credit. The deficient harvests of 1838 and 1839, conspiring with this redundancy, occasioned a farther fall in the exchange, and a severe drain upon the Bank of England for gold. But while the latter was narrowing her issues by supplying the exporters of bullion with gold in exchange for notes, the country banks went on increasing their advances!

What the former did by contracting on the one hand, the latter more than undid by letting out on the other; and in the end, the bullion in her coffers in August 1839 was reduced to 2,420,000*l.*, so that we narrowly escaped a tremendous crisis.

This perilous experience having again forcibly attracted the public attention to the state of our banking system, Sir Robert Peel was induced to attempt its improvement. The clause in the Act 3 & 4 Wm. IV. c. 98, for the renewal of the charter in 1833, which gave to parliament power to revise or cancel it in 1845, afforded a legitimate opportunity for the introduction of the new system. But, however desirable, the total suppression of the issue of notes by joint-stock and private banking companies would have been a measure too much opposed to popular prejudices, and to the real or supposed interests of a large and powerful class, to have had any chance of being carried; and there would also have been great, though inferior, difficulties in the way of the plan for taking security from the issuers. It was indeed indispensable, in attempting to obviate the defects inherent in our banking system, to proceed cautiously; to respect, in as far as possible, existing interests, and to avoid taking any step that might excite the fears or suspicions of the public; the grand difficulty being to reconcile the introduction of such a course with the adoption of any plan that would obviate in any considerable degree the defects complained of. Happily this difficult problem was satisfactorily solved by Sir Robert Peel; the measures he introduced and carried through parliament in 1844 and 1845, for the improvement of our banking system, having been so skillfully contrived as to provoke little opposition, at the same time that they effected very extensive and (as we think) most beneficial changes.

The measures in question consisted of the Act 7 & 8 Vict. c. 32, which refers to the Bank of England, and the English country banks; and the Acts 8 & 9 Vict. c. 37, 38, referring to the banks of Scotland and Ireland. The principal object of these statutes has been to obviate the chances of over-issue and of sudden fluctuations in the quantity and value of money, by limiting the power to issue notes payable on demand, and by making the amount of such notes in circulation vary more nearly than previously with the amount of bullion in the possession of the issuers. Sir Robert Peel adopted, in dealing with the Bank of England, the proposal made by Lord Overstone in 1837, for effecting a complete separation between the issuing and banking departments of that establishment. And while the directors are left at liberty to manage the latter at discretion, their management of the former, or issue department, is subjected to what is meant to be a rigid system of restraint. The Bank is allowed to issue 14,000,000*l.* of notes upon securities (of which the debt of 11,016,100*l.* lent by her to government is a part); and for whatever paper the issue department may at any time issue over

BANK

and above this maximum amount of securities, it must have an equal amount of coin and bullion in its coffers. Hence it is impracticable for the issue department to increase its issues without, at the same time, proportionally increasing its stock of coin and bullion; or to diminish the latter without proportionally diminishing the amount of paper supplied to the public and the banking department. It is no longer, as formerly, in the power of the Bank to create paper money at pleasure to supply the place of cash in any emergency in which she may be involved; and instead of less, she requires to act with more circumspection under the new system than under the old.

Weekly returns are now published of the issues of the Bank, and of the securities, bullion, &c. in her possession. The sum to be deducted by the Bank from the charge on account of the management of the national debt is in future to be 180,000*l.* instead of 120,000*l.* a year, as fixed by the Act 3 & 4 Wm. IV. c. 98. The charter since the 1st of August 1856 may be terminated at any time on twelve months' notice.

The provisions made in the Act of 1844 for restraining the country circulation were, perhaps, still more important. The maximum future issue of the joint-stock and other banks in England and Wales was limited to the average amount of the circulation of each during the twelve months preceding the 27th of April 1844; the aggregate being 3,477,321*l.* for the joint-stock, and 5,011,097*l.* for the private banks. It was farther enacted that no new bank shall be established for the issue of notes, and that the names of the partners in joint-stock and other banks shall be published annually in February.

The regulations in the statutes relating to banking in Scotland and Ireland are nearly similar. The maximum amount of notes to be issued by the banks of both countries is, in time to come, not to exceed the average amount which each bank had in circulation during the twelve months ending the 1st of May 1845. Certain returns, including amongst others the amount of gold and silver coin held by the banks, the names of the partners, &c., are to be periodically published. The small-note currency of Scotland has not been affected by the measure.

Limited Liability Act, 25 & 26 Vict. c. 89, passed August 7, 1862.—This is a general Act for the 'Incorporation, Regulation, and Winding-up of Trading Companies and other Associations,' and is founded chiefly on the consolidation of a variety of statutes passed during the previous ten years. For the first time in this country the Act extended to non-issuing joint-stock banking companies the privilege or principle of limited liability; that is to say, the Act prescribed that no partner in such banks should be liable for more than the total amount of the shares standing in his name, instead of, as under the former law, for the whole amount of his fortune. The immediate effect of the Act of 1862 was to occasion

a violent mania for the establishment of limited-liability banks.

It may be here convenient to point out to students, that the principal reports of parliamentary committees are the following: 1797 (Lords and Commons), on the Suspension of Payment by the Bank of England; 1810, Bullion Committee; 1819 (Lords and Commons), on the Resumption of Cash Payments; 1832, on the Bank of England Charter; 1840, on Banks of Issue; 1848 (Lords and Commons), on the Commercial Distress of 1847; 1866-67 (Commons), on Bank Acts.

The measures adopted in 1844, though they deeply affected many powerful private interests, were passed with little difficulty, and were very generally approved of. In this respect, however, the public opinion has, to some extent, changed; and the Act of 1844 has been charged by various parties with having aggravated the pressure experienced by the mercantile world in 1847 and 1857. The crisis of 1847 was a consequence, partly of the railway mania of the previous year, and partly of the failure of the potato crops of 1845 and 1846. The failure in the latter year deprived fully two-thirds of the people of Ireland, and a considerable portion, also, of those of Great Britain, of their accustomed supplies of food. In consequence, there was an unprecedented importation of all sorts of corn, and a corresponding demand for bullion for exportation to meet this importation.

A great many mercantile houses that had been trading upon very insufficient capitals, or which had previously been virtually insolvent, were, of course, swept off during the crisis; and the alarm thus occasioned, though for the most part without any good foundation, gave rise to a species of panic. During the prevalence of the latter, government consented (25th October 1847) to a temporary suspension of the Act of 1844.

The difficulties of 1857 grew out of the bankruptcy of the banks in the United States in that year, and the consequent difficulty of obtaining payments of exports made to them; these circumstances having injuriously affected parties in Glasgow and elsewhere, who were largely indebted to different banking companies. The solidity of some of the latter came to be suspected, and symptoms of an internal panic began to make their appearance—and as it was most probable that bankruptcies on a large scale could not be avoided, and as no amount of bullion in the coffers of the Bank of England can resist a *bonâ fide* run originating in such a cause, the Act of 1844 was properly suspended till the panic was over.

In 1864 occurred another severe crisis in the money market. The extensive commercial disturbance caused by the stoppage of the supply of raw cotton from the United States, in consequence of the civil war in that country, and by the vast speculations primarily suggested by the passing of the Limited Liability Act of 1862, led, in the autumn of 1863, to a rapid

BANK

rise to 8 per cent. of the minimum rate of discount at the Bank of England. The rate fluctuated considerably in the early part of 1861, but in May it reached 9 per cent. It again fell; but on September 8 it a second time reached 9 per cent., and remained at that point till November 10. During these two months the country passed through a severe crisis. Failures were numerous and for large amounts, and the destruction of credit very considerable; and it was generally admitted, that the firm and sagacious manner in which the Bank of England was managed, during the period of difficulty, had a most important share in preventing a national calamity. The governorship of the Bank was in the hands of Mr. Kirkman Hodgson.

Scotch Banks.—The Act of 1708, preventing more than six individuals from entering into partnership for carrying on the business of banking, did not extend to Scotland. In consequence of this exemption, several banking companies, with numerous bodies of partners, have always existed in that part of the empire. The Bank of Scotland was established by Act of Parliament in 1695. By the terms of its charter it enjoyed, for twenty-one years, the exclusive privilege of issuing notes in Scotland. Its original capital was only 100,000*l.*; but it was increased to 200,000*l.* in 1744 and now amounts to 1,500,000*l.*, of which 1,000,000*l.* has been paid up.

The Royal Bank of Scotland was established in 1727. Its original capital was 151,000*l.*; at present it amounts to 2,000,000*l.*, which has been all paid up.

The British Linen Company was incorporated in 1746, for the purpose, as its name implies, of undertaking the manufacture of linen. But the views in which it originated were speedily abandoned, and it became a banking company only. Its paid-up capital amounts to 1,000,000*l.*

Exclusively of the above, there are two other chartered banks in Scotland: the Commercial Bank, established in 1810; and the National Bank of Scotland, established in 1825. The former has paid-up capital of 800,000*l.*, and the latter of 1,000,000*l.*

None of the other banking companies established in Scotland are chartered associations; and the partners are jointly and individually liable to the whole extent of their fortunes for the debts of the firms. Some of them, as the Aberdeen Town and Country Bank, the Dundee Commercial Bank, the Perth Banking Company, the Glasgow Bank, &c., have very numerous bodies of partners. Generally speaking, they have been eminently successful. Their affairs are uniformly conducted by a board of directors chosen by the shareholders. All the great joint-stock banks have numerous branches, so that there is hardly a town or village of any consequence without one or more banks.

The Bank of Scotland began to issue one-pound notes as early as 1704, and their issue has since been continued without interruption. All the Scotch banks issue notes, and taking their

aggregate circulation at from 3,800,000*l.* to 4,000,000*l.*, it is supposed that from 2,000,000*l.* to 2,500,000*l.* consists of notes for 1*l.* In 1826 it was proposed to suppress one-pound notes in Scotland as well as in England; but the measure, having been strongly objected to by the people of Scotland, as at once oppressive and unnecessary, was abandoned.

Until lately there have been very few bankruptcies amongst the Scotch banks. This superior stability is to be ascribed to a variety of causes; partly to the great wealth of the early established banks, which had a considerable influence in preventing an inferior class of banks acquiring any hold on the public confidence; partly to the comparatively little risk attending the business of banking in Scotland; partly to the facilities afforded by the Scotch law for attaching a debtor's property, whether it consist of land or movables; and partly, perhaps, to the fact of the Scotch banks being but indirectly and slightly affected by the depression of the exchange and an efflux of bullion.

No doubt, however, the greater stability of the Scotch banks has been mainly ascribable to the comparative absence of speculation and to the greater security of the country trade. Latterly, however, or since the extraordinary rise of Glasgow and Dundee, matters have in this respect totally changed; and banking in Scotland has become quite as hazardous and has been quite as badly managed as in any other division of the United Kingdom. In 1857 two of the principal Scotch banks stopped payment; one afterwards resumed payment, but the other, the Western Bank, which had above 1,200 shareholders, with a large capital and an immense amount of deposits, became totally bankrupt. So great was the calamity, that the shareholders of the bank sustained a total loss of more than 2,000,000*l.* sterling. Many of them were reduced to a state of poverty. No such catastrophe had ever before occurred through banking in Scotland; and this striking example shows that banks unless it be conducted carefully and cautiously, may degenerate in Scotland, as elsewhere, into an unmixled and gigantic evil.

The commerce and population of Scotland are too limited, and it is too remote from the metropolis, or from the centre of the money market, the pivot on which the exchanges turn, to make it of importance that her currency should be in all respects identical with that of England. We believe that the Scotch attach much more importance than it deserves to the issue of paper, and especially to the issue of one-pound notes; still, however, we do not think that the circumstances are at present such as to call for or to warrant any attempt to introduce any material changes in their banking system.

All the Scotch banks receive deposits, even of the low amount of 10*s.*, and allow interest on them at from one to two per cent. below the market rate. But should a deposit be unusually

BANK

large, as from 5,000*l.* to 10,000*l.*, a special agreement is usually made with regard to it. This part of the system has been particularly advantageous. It renders the Scotch banks a sort of savings banks for all classes; and their readily receiving all sorts of deposits, at a reasonable rate of interest, has tended to diffuse a spirit of economy and parsimony among the people that would not otherwise have existed. The total deposits in the hands of the Scotch banks are believed at present (1864) to exceed 50,000,000*l.*, of which fully a half is understood to be in sums of from 10*l.* to 200*l.*

The Scotch banks make advances in the way of discounts and loans, and on what are called cash-credits or cash-accounts. By the latter are meant credits given by the banks for specified sums to individuals, each of whom gives a bond for the sum in his account, with two or more individuals as sureties for its payment. Persons having such accounts draw upon them for whatever sums within their amount they have occasion for, repaying these advances as they find opportunity, but generally within short periods. Interest is charged only on the average balance which may be found due to the bank. The total number of these accounts in Scotland in 1826 was estimated at about 12,000; and it may now, perhaps, be taken at about 16,000. They are believed to average about 500*l.*; few are for less than 100*l.* and fewer still above 5,000*l.*

It has been contended by no less an authority than Adam Smith, that this species of accommodation gives the Scotch merchants and traders a double command of capital. 'They may discount their bills of exchange,' he says, 'as easily as the English merchants, and have, besides, the additional convenience of their cash accounts.' But this is an obvious error. The circulation will take off only a certain quantity of paper; and to whatever extent it

may be issued by means of cash-accounts, so much the less can be issued in the way of discounts. The advantage of a cash-account does not really consist in its enabling a banker to enlarge his advances to his customers, but in the extreme facility it affords of making them. An individual who has obtained such an account may operate upon it at any time he pleases, and by drafts for any amount; an advantage he could not enjoy to anything like the same extent, without an infinite deal of trouble and expense, were the loans and advances made to him through the discounting of bills. The Scotch banks draw upon London at seven days' date. This is denominated the par of exchange between London and Edinburgh.

Irish Banks.—The Bank of Ireland was established in 1783, and the same restriction as to the number of partners in other banks that formerly prevailed in England was enacted in its favour. Owing to that and other causes the bankruptcies of private banks have been more frequent in Ireland than in England. In 1821 this restriction was repealed, as respects all parts of the country more than fifty Irish miles from Dublin. Since that period several banking companies, with large bodies of partners, have been set on foot in different parts of the country; of these the Provincial Bank, founded on the Scotch model, is among the most flourishing. The Bank of Ireland is now governed by the Act 8 & 9 Vict. cap. 37. The Irish as well as the Scotch banks issue notes for 1*l.*

For accounts as to foreign banks, see *Commercial Dictionary*, and the art. 'Money' in the 8th edition of the *Encyclopædia Britannica*, with the authorities there referred to.

We subjoin the following particulars in regard to the bank-note circulation of the United Kingdom and the bullion in the Bank of England, in each year since 1844:—

Years	England and Wales			Total England and Wales	Total Scotland	Total Ireland	Total United Kingdom	Average Bullion in Bank of England
	Bank of England	Private and Joint-stock Banks						
		Private	Joint-stock					
	£	£	£	£	£	£	£	£
1815	21,730,000	4,510,000	3,190,000	29,430,000	3,290,000	6,950,000	39,670,000	15,330,000
1816	21,250,000	4,550,000	3,170,000	28,970,000	3,400,000	7,260,000	39,630,000	14,680,000
1817	20,110,000	4,510,000	3,090,000	27,710,000	3,550,000	6,910,000	37,700,000	10,610,000
1818	19,070,000	3,660,000	2,600,000	26,330,000	3,630,000	4,750,000	34,410,000	13,760,000

Colonial and Foreign Banks.—During the last fifteen years a large number of banks have been formed in this country for transacting

banking business in the colonies and foreign countries. These banks are in effect joint-stock companies having their operations abroad,

BANKS FOR SAVINGS

but constituted by shareholders in this country who subscribe the capital, appoint the directors, and, as in the case of any other joint-stock enterprise under English law, are the ultimate responsible parties. The seat of management of most of these banks is in London. Prior to the simplification of the joint-stock law some few of these banks obtained charters or letters patent. But the tendency is now to take advantage of the Limited Liability Act of 1862, already referred to. As a rule these colonial banks have been successful, and they have certainly facilitated to a large extent the growth of foreign trade.

In the course of 1863 a class of quasi-banks were introduced into this country under the name of Finance Companies. The model pointed at was that of the *Credit Mobilier* at Paris. The finance companies do not undertake banking business of the ordinary kind; that is to say, they do not keep current accounts and pay cheques, nor do they discount bills as bankers are in the habit of doing for their custom.

The finance companies obtain funds first by means of their paid-up capital, and secondly by means of sums taken from the public on deposit at full rates of interest and for long periods. The means thus acquired are employed in making advances to contractors of public works, in assisting railway and other similar undertakings with loans, and generally in fostering species of enterprise not within the province of a prudent banker having large liabilities payable on demand. These companies are already very numerous, and it is impossible yet to pronounce an opinion upon the position they may in the end occupy. There need be no hesitation, however, in saying that in many instances expectations have been held out, and received with favour, of a character so extreme as to be foolish and absurd.

Banks for Savings. Banks established for the receipt of small sums deposited by the poorer class of persons, and for their accumulation at compound interest. Though not so well calculated as friendly societies to enable the labouring classes to provide against sickness and old age, savings banks are very valuable institutions, and are eminently entitled to the public patronage and support. The want of a safe place of deposit for their savings, where they would yield them a reasonable interest, and whence they could withdraw them at pleasure, has formed one of the most serious obstacles to the formation of a habit of accumulation among labourers. Public banks do not generally receive a less deposit than 10*l.*; and there are but very few amongst the labouring classes who find themselves suddenly masters of so large a sum, while to accumulate so much by the weekly or monthly saving of a few shillings appears at first view almost a hopeless task; and should an individual have the resolution to attempt it, the temptation to break in upon his little stock at every call of necessity might be too strong to resist. At all

events, the progressive addition of interest is lost during the period of accumulation: and it even frequently happens that the chest of the servant or labourer is not safe from the depredations of the dishonest; while the very feeling of insecurity which such a circumstance inspires must operate as a fatal check to habits of saving. A similar effect results from the instances that have often occurred, where those poor persons who had, in despite of every discouragement, accumulated a little capital, have been tempted, by the offer of a high rate of interest, to lend it to persons of doubtful characters and desperate fortunes, whose bankruptcy has involved them in irremediable ruin. It is plain, therefore, that nothing could be more advantageous with a view to the formation of those improved habits that must necessarily result from the diffusion of a spirit of frugality and forethought among the poor, than the institution of savings banks, or places of safe, convenient, and advantageous deposit for their smallest savings. They are no longer tempted, from the want of facility of investment, to waste what little they can save from their expenditure in frivolous or idle gratification.

They now feel assured that their savings, and interest accumulated upon them, will be faithfully preserved to meet their future wants, and as there are very few who are insensible to the blessings of independence, there is no reason to suppose that they will be slow to avail themselves of the means of accumulation now in their power.

All moneys paid into any savings bank established under the present regulating Act (stat. 26 & 27 Vict. c. 87) are ordered to be paid into the banks of England and Ireland, and invested in Bank annuities or Exchequer bills. The interest payable to depositors is not to exceed 3*l.* 6*s.* 10*d.* per cent. per annum. No depositor can contribute more than 30*l.*, exclusive of unpaid interest, to a savings bank in any one year; and the total deposits to be received from any one individual are not to exceed 150*l.*; and when compound interest, and compound interest accruing upon them, standing in the name of any one individual, shall amount to 200*l.*, no further interest shall be paid upon such deposit.

A large amount of inquiry and legislation has taken place of late years on the subject of savings banks. In several instances, especially at Tralee, Bilton, and some other places, disgraceful failures of savings banks have taken place in consequence of misconduct on the part of the persons officially in charge of them, and attempts were made to fix responsibility upon the Treasury. These claims were naturally resisted as wholly untenable. The government pointed out that it had never come under any guaranty to the depositors for the ultimate safety of their funds, and that the claimants must look to the trustees and managers.

Post-Office Savings Banks.—In order, however, to provide to some extent for the poorer

BANKRUPTCY

classes a mode of accumulating savings in the most convenient manner and under the security of a perfect guaranty by parliament, Mr. Gladstone procured the passing of the Act 24 Vict. c. 14 (May 27, 1861), under which the Post-Office is empowered to employ its organisation for savings bank purposes. The interest allowed is $2\frac{1}{2}$ per cent. per annum, and great facilities are given to depositors. At the close of 1863 the amount of capital in Post-Office savings banks was three and a half millions sterling, and in savings banks under the old regulations forty-one millions sterling. For the first practical suggestion of Post-Office savings banks the public are indebted to Mr. C. Sikes of Huddersfield.

Besides the savings banks of the more regular form, it has become a useful practice of late years for parochial authorities and others to encourage Penny Savings Banks, where sums as small as a single penny are taken; and in many cases the amounts collected in this way have been surprisingly large.

Bank-note Printing. [PRINTING.]

Bankruptcy (Ital. *banca-rotta*, a bankrupt whose *banco* or place of business is broken up: Wedgwood, *Dictionary of English Etymology*). In Law, the condition of a trader declared by legal authority unable to meet his engagements; regulated in England by a variety of statutes, from the 34 Hen. VIII. to 24 & 25 Vict. c. 134 (1861). The subject of bankruptcy has been one of the most difficult and hitherto unsatisfactory subjects of legislation in this country for a long period. In 1842 and 1849 elaborate Acts were passed, intended to have the effect of consolidating and simplifying the law; but, as experience showed, with only very partial success. Prior to 1842, the granting or refusing of a certificate of discharge to a bankrupt was almost wholly in the hands of his creditors, each of them acting for himself; and the abuses entailed by this system in the form of preferences and other improper modes of removing opposition, were so flagrant, that the legislature were led to confine the adjudication of certificates to the Court of Bankruptcy alone; and in order, as it was thought, to make a useful and just distinction between bankrupts, certificates were required to be of the first, second, or third class. Down to 1861, the law distinguished between traders and non-traders, and between bankruptcy and insolvency. In 1861, after much discussion, the bankruptcy and insolvency laws were again remodelled by the Act 24 & 25 Vict. c. 134 (Aug. 6, 1861); the present Lord Chancellor, Lord Westbury, then Sir Richard Bethell, taking charge of the measure. By this statute the difference between traders and non-traders, which had theretofore pervaded the law of England, was abolished; the Courts of Insolvency, with their peculiar jurisdiction, cease to exist; and the following is now the outline of English jurisprudence on the subject. Jurisdiction is vested in three commissioners in London; in the county court judges

out of London. All persons become subject to the law (whether traders or not) who may have committed acts of bankruptcy. The principal of these acts are, 1. In the case of non-traders, departing or remaining out of the realm with intent to defraud creditors; 2. Remaining in prison two months (or fourteen days in the case of traders) for debt; or escaping therefrom; 3. Non-trader or trader, filing a declaration that he is unable to meet his engagements; 4. Traders suffering execution to be levied; 5. Non-payment after judgment debtor's summons. A person who has committed one of these acts may be made a bankrupt on petition from a creditor to the amount of 50*l*. But any debtor may also petition to be adjudicated a bankrupt, and such petition is an act of bankruptcy. A prisoner for debt may petition *in forma pauperis*.

On proper proceedings being taken by the creditor, adjudication of bankruptcy takes place, on which the bankrupt's property is taken possession of by an officer of the court styled the official assignee, who holds it until the creditors who have proved their debts choose (if they think fit) a creditors' assignee for themselves. His duty is to manage, realise and recover the estate of the bankrupt, except debts under 10*l*., which are still to be recovered by the official assignee. Not later than sixty days after the meeting for the choice of an assignee the bankrupt appears to pass his last examination, state his accounts, and apply for discharge. Proof of debts by creditors may be made at any due time after adjudication and prior to the last meeting. The bankrupt is ultimately discharged, unless he has been either guilty of fraud amounting to a misdemeanour under the Act, and convicted thereof, or of misconduct specified in the Act but not amounting to misdemeanour: in either of which cases the court may suspend or refuse the discharge. The order of discharge frees the bankrupt, subject to certain exceptions, from all debts and liabilities. Provision is made for the distribution of his estate among creditors who have proved their debts, by successive dividends. Provision is also made in certain cases for substituting composition or arrangement for the proceeding to bankruptcy. An appeal lies under this Act, and the 1 & 2 Vict. c. 110, from proceedings in bankruptcy to the Lord Chancellor and Court of Appeal in Chancery sitting in bankruptcy.

It was strongly urged by the promoters of the statute of 1861, that in order to render any bankruptcy law effective, it must be administered in chief by a single responsible judge, and hence they proposed to establish a chief judge in bankruptcy, invested with powers sufficiently large to enforce the bankruptcy law in all its branches. An opposition, however, in which it is lamentable to add that mere party intrigue had a large share, defeated this part of the scheme, and the statute was finally passed with provisions which left the machinery of the old system of commissioners,

BANKRUPTCY

official assignees, registrars, ushers and messengers almost unchanged.

The measure of 1861 has not succeeded, and the discontent occasioned by it led to the appointment in 1864 of a Select Committee of the House of Commons, under the chairmanship of Mr. Moffatt. It is probable that the investigations of this committee will lead to another early remodelling of the English bankruptcy system, and hence we may usefully indicate, by means of a draft report presented to the committee by Mr. Moffatt (July 1864), the nature of the views now largely entertained as regards the defects of the present system, and the principles to be followed by those who desire to reform it. It is said that at present there is a great difficulty in punishing fraudulent bankrupts; that the decisions of the commissioners are most conflicting and uncertain; and that the creditors' property is negligently protected, and wasted by excessive expenses. It is said that the failures of the last forty years seem to prove that any bankruptcy Act which vests in a court of law the collection and management of the estates of bankrupts, is unsound and sure to fail. The remedy, it is said, seems to be the adoption in effect of the system which has been for some time in force in Scotland (the last Scotch Act is 19 & 20 Vict. c. 79). Under that system the creditors are left to manage the collection and distribution of the assets of the insolvent with the least possible interference of the law, only retaining an appeal to a court to prevent malversation, secure equitable distribution, and prevent fraud. It is also strongly urged that it is necessary to create a chief judge in bankruptcy, invested with powers of adjudication similar to those of the judges in equity, and of punishment similar to those formerly held by the Chief Commissioner of the Insolvent Debtors Court.

In France, the bankruptcy law was largely remodelled in 1838; and, as then settled, the plan appears to have worked tolerably well. It must be always remembered that failures in France are much more simple in all respects than in England, arising from the limited trade of France as compared with this country. The Code de Commerce (arts. 586-6) defines 'simple bankruptcy' as follows; and art. 402 of the Penal Code punishes 'simple bankruptcy' by imprisonment of not less than one month, nor more than two years. 'Simple bankruptcy' is held to have been committed, 1. If the personal expenses of the bankrupt have been excessive; 2. If he has wasted large sums in gambling or gambling operations; 3. If he has resold goods under the current price, or raised loans by pledging goods according to extravagant methods; 4. If he has entered into improvident engagements for other persons; 5. If he fails a second time before fully paying his debts under a former failure; 6. If he has not kept any, or only imperfect, books. Art. 591 of the Code de Commerce defines fraudulent bankruptcy to be concealing of books or assets, and fraudulently acknowledging obligations for

BANNER

which no real equivalent has been received. Art. 402 of the Penal Code punishes fraudulent bankrupts by imprisonment with hard labour 'for a period of time.'

Banksia (in honour of Sir Joseph Banks, the eminent patron of natural history, and one of the companions of Captain Cook in his second voyage). A genus of Proteaceous plants forming a conspicuous feature in the landscape of Australia, where the species are called by the colonists wild honeysuckle, and reckoned a sign of bad land. They have flowers and fruit growing in close hard downy or woolly cones, and hard, often broad leaves, on branches so close and rigid that the traveller, it is said, may literally walk without inconvenience upon the top of a wood formed of these trees.

Banlieue (Fr.). The territory without the walls, but comprised within the legal limits of a city or town.

Bann. [BAN.]

Banner (Ital. bandiera; Fr. bannière). A flag or standard under which men are united or bound for some common purpose. Mr. Wedgwood (*English Etymology*) derives this word from the Gothic *bandwa*, a sign or intimation made by *bending* the head or hand. Among the ancient Germans, the honour of bearing a banner was conferred by the emperor on the man who could bring ten vassals into the field. In latter times, petty princes assumed this privilege; and in the year 1424 Pope Eugenius IV. created Count Sforza banneret (bannerherrn) of the Roman empire. In the free towns on the Continent the banner was always carried by the chief magistrate *ex officio*, in solemnities or grand processions. In England, a knight banneret was created by the ceremony of cutting off the four corners of his standard and making it square. Some antiquarians trace the origin of this custom to Conan, the lieutenant of Maximus, who governed Britain in the year 383 (Gwillim, *Analogia Honorum*); while others maintain that it took its rise from the Black Prince on the field of Cressy. A great similarity seems to exist between the duties and privileges of the old knights bannerets of England and those of the *centurio principii* (the standard bearers) among the Romans. (Tacit. *Hist.* iii. 22.) Several banners are famous in history; such as the Danish banner, taken from the Danes by Alfred the Great; and the oriflamme of the French, which, after passing through various hands, became finally the great standard of France. [ORIFLAMME.]

BANNER. In modern Military usage, the word *banner* has been discontinued, except for the small flags attached to the drums and trumpets of cavalry regiments, which must be of the colour of the facings of the regiment. The flags used in the infantry are called *colours*; in the cavalry, *standards* or *guidons* [COLOURS; GUIDON; STANDARD.]

Banneret. An officer of the city of London in mediæval times, whose duty was to bear

BANNERET

the banner of the city in time of war. His privileges are defined in Blount's *Ancient Tenures*.

Banneret. A knight or feudal lord, who, when summoned by the king, led his vassals to battle under his own flag or banner. This honour was also very generally adopted among European nations, and was awarded on the field of battle to such as had there distinguished themselves. Knights bannerets were considered, in England, next to barons in precedence. The dignity has not been conferred for a long period. The banner of a banneret was oblong, that of a baron square. When a knight bachelor was made banneret on the field of battle, the ceremony was performed by cutting off the ends or tails of his pennon, and thus converting it into a banner. [KNIGHT.]

Bannerole. A small flag used to mark the position to be taken up by the flank of a regiment at a review, in deploying, &c.

Banquette (Fr.). In Fortification, is a raised bank or step running along the inside of the parapet, to enable the soldier to fire over it.

Banshie. In the Mythology of Ireland, a spectre in female form, whose special office it is to announce the approaching death of the living. Such a spectre is assigned to certain families of ancient descent; and some one of the family, it is believed, is sure to die whenever the banshie is seen weeping. A similar superstition is found in Scotland, where the Bodach Glas, or Grey Spectre, plays the part of the banshie. (Sir W. Scott, *Waverley*, ch. xxx.)

Banyan. A kind of Indian Fig, the *Ficus indica* of Linnaeus, forming a very large tree, which sends down roots from its branches, and these roots striking into the ground, themselves become trunks, which serve as props to the extending branches. As the tree is very long-lived, the quantity of ground covered by a single tree is almost incredible. Dr. Roxburgh says, he has seen the tree 100 feet high, and full 500 yards in circumference round the extremities of the branches. It is found wild in the skirts of the Circar mountains; its leaves are used by the Brahmans as plates to eat off; a species of birdlime is obtained from its juice; and the fruit is eaten by birds.

Baobab. The African name of *Adansonia digitata*, a tree inhabiting the western side of Africa, and cultivated in Egypt and Abyssinia. It increases in proportion more in diameter than in height; so that it may be seen with a trunk 10 yards in thickness and only 73 feet high, its appearance being lumpish and inelegant. It is supposed that the most remarkable cases of longevity in the vegetable kingdom are afforded by this tree. Adanson is quoted by De Candolle as asserting that he saw trees which must have been 6,000 years old; and other travellers declare that, however ancient the trees may be, the bark is always green and shining, and so full of life that an abundant discharge takes place at the least wound. It is probable that the data upon which these calculations are made will not bear strict investigation; nevertheless, there can be no

BAPTISM

reasonable doubt of the Baobab trees arriving at a most unusual age. The leaves are employed in powder as an ingredient in African cookery; and the fruit has a sub-acid juice, which makes it valuable in fevers.

Baphia (Gr. *Baph*, a dipping). A genus of *Leguminosae*, consisting of West Tropical African trees, one of which (*B. nitida*) produces the Camwood or Barwood of commerce, much used for dyeing purposes.

Baphomet. The imaginary idol, or rather symbol, which the Templars were accused of employing in their mysterious rites. [TEMPLARS.] The distinguished orientalist, Von Hammer, published a dissertation on this subject, in which he endeavoured to revive the ancient accusations against that military order. These images, which he calls Baphomet, are to be found in some of the museums of continental cities; they are small human figures with two heads, and covered with emblems, to which Von Hammer attaches a very horrible signification. He derives the name (very improbably) from the Greek words *Baph*, dipping or baptism, and *phris*, counsel or wisdom: as if they represented the admission of the initiated to the secret mysteries of the sect. It is proper to observe, that other writers have treated all this discovery as a mere fancy of the learned orientalist, and maintain that the figures which he terms Baphometes are in reality relics of the art magic: while the word itself is supposed to be a corruption (arising from the negligence of some transcriber) of the name Mahomet, occurring in the depositions of witnesses against those unfortunate knights. (Hallam, *Middle Ages*, ch. i. note 16; Milman, *Latin Christianity*, book xii. ch. ii. p. 204.)

Baptism (Gr. *Baptisma*). The rite of initiation into the community of Christians, ordained by Christ Himself, when He commissioned His apostles to go and baptise all nations in the name of the Father, the Son, and the Holy Ghost (St. Matt. xxviii. 19).

It is recorded by the Evangelists, that our Saviour Himself received baptism from John; and the ceremony which the Baptist performed is allowed generally to have been an imitation of a rite in common practice among the Jews, who appear to have admitted proselytes by circumcision and baptism. Lustration, however, by water, as an initiatory rite, is of great antiquity in the East; and Christian baptism may be considered as an adaptation of a form which was generally understood to have a symbolical meaning. Accordingly, it has been recognised by all Christian communities admitting sacraments as a sacrament, although they have differed in their explanation of its nature and meaning. It is upon this point that the question of the validity of infant baptism principally depends; the words of Scripture in that particular not being allowed on all hands to be decisive, nor even the practice of the early church universally admitted. Those, therefore, who consider baptism to be a symbol of a covenant thereupon entered into between God

BAPTISTERY

and the person baptised, require the understanding of the person to accompany the act, and reject the notion of sponsors undertaking to promise on the part of infants; while those who hold the belief of the Eastern and Roman churches, and those Protestant bodies which most nearly approach them, conceive this sacrament to have in itself a regenerative virtue, by which an infant may be received into participation in the promises made to the church, and be really and truly from that time forth put into the way of salvation.

Baptism was originally administered by immersion, which act is thought by some to be necessary to the sacrament. It is not clear, however, even in the Scripture history, that this ceremony was always adhered to. At present sprinkling is generally substituted for dipping, at least in northern climates. The Greek church, however, requires immersion.

Baptistery (Gr. *Βαπτιστήριον*). In Architecture, a building destined for the purpose of administering the rite of baptism. Some authors have contended that the baptistery was anciently placed in the interior vestibules of the early churches, as are in our days baptismal fonts. But this is not so: the baptistery was entirely separated from the basilica, and even placed at some distance from it. Up to the end of the sixth century, after which period the interior vestibule of the church received it, the baptistery was distinct from the church; and excepting in a few churches, as at Florence and Ravenna, in San Giovanni Laterano, and perhaps a few others, the practice was general. The last mentioned is perhaps the most ancient remaining. One at Constantinople was so large that on one occasion it held a very numerous council. The baptistery of Florence is nearly 90 feet in diameter, octagonal, and covered with a dome. The celebrated bronze gates by Lorenzo Ghiberti, which Michael Angelo said were fit to be the gates of Paradise, enclose it. The baptistery at Pisa was finished about 1160. It is octagonal, about 129 feet in diameter, and 179 feet high. We are not aware of any building of this sort having been erected in England, unless the octagonal porch of St. Mary Redcliff, at Bristol, be cited as an example. [Ansrs.]

Baptists. A denomination of Christians, who deny the validity of infant baptism, and maintain the necessity of immersion. These were also the principal tenets of the Anabaptists, or Rebaptisers, with whom, however, the modern Baptists ought not to be confounded. They are subdivided into two classes, the Particular (Calvinist) and the General (Arminian) Baptists. The mode of church government is similar with both, acknowledging three orders of ministers; of whom the messengers correspond to bishops, the elders to priests, and ministering brethren to deacons. Their churches are congregational, and in respect to the election of their own ministers independent. Each denomination has, however,

BARBADOES NUTS

its general assembly, possessing some kind of authority over the whole community. The Baptists are numerous in Holland, where they are known by the title of Mennonites; and in England they form one of the principal Dissenting bodies. The total number of places of worship belonging to Baptists of various denominations in England and Wales amounted in 1851 to about 2,700. [Census.]

Bar. A bar is obstructive to trade, inasmuch as vessels of any considerable burden have to wait until high tide before they can pass it. The bar, like a delta, usually owes its existence to the deposits brought down by the river at the mouth of which it is situated.

Bar. In Heraldry, a kind of ordinary, resembling the *fess*, but containing only the fifth part of the field. Where two bars are borne in an escutcheon, they are so arranged that the whole field appears divided into five parts. A field divided by horizontal lines into four, six, eight, ten or twelve equal parts, with alternate tinctures, is termed *barry* of four, six, eight, &c.

Bar. In Law, the place in the courts where barristers or advocates plead: also where prisoners accused of felony are stationed for arraignment and trial.

Bar (Ital. *barra*, Fr. *barre*, a *beam* or *pole*). In Music, a line drawn vertically across the lines of the staff. The bars divide off the music into equal portions of time, each of which is called a bar or measure: the quantity or position contained in each is indicated by a certain mark at the commencement of the piece.

Bar, Confederation of. In Politics, was an association of a few influential Polish nobles, formed at Bar, a small town of Podolia, in the year 1767, for the purpose of freeing their country from foreign influence. Their efforts, however, were eminently unsuccessful: the small bands of the patriots were annihilated one by one; and their defeat gave rise to an event almost unprecedented in history—the partition of Poland by the three neighbouring Powers.

Baralite. A hydrated silicate of alumina, peroxide of iron, lime and magnesia found at Baralon, Côte-du-Nord, in France.

Barba (Lat. a *beard*). In Botany, a term used to denote any collection of long loose hairs into a tuft or crest, as on the petals of the Iris. Barbelle are the short stiff hairs on the pappus of composite plants.

BARBA. In Mamalogy, signifies the long tuft of hair dependent from the under jaw. In Ornithology, the same term is applied to the setiform or simple feathers, which in some species of birds depend from the skin covering the gullet or crop. In Ichthyology, a kind of spine, with the teeth pointing backwards.

Barbadoes Leg. A disease indigenous to Barbadoes, in which the limb becomes tumid, hard, and misshapen.

Barbadoes Nuts. The fruit of the *Jatropha Curcas*, a native of South America and

BARBADOES TAR

Asia. They are sometimes called *physic nuts*, and are virulently purgative.

Barbadoes Tar. A name often given to Petroleum [which see].

Barbarism (Gr. *βαρβαρισμός*). In Rhetoric, an offence against purity of style or language, which consists in employing uncouth or antiquated expressions, or in assigning to terms a different signification from that which usage has conferred on them.

Barbastelle. A small indigenous bat; *Plecotus barbastellus*, Linn.

Barbel. An indigenous fresh-water fish (*Cyprinus barbatus*, Linn.), which takes its name from the processes termed Barbels.

Barbellate (Lat. *barba*, a beard). Bearded by short, stiff, straight bristles, as in the pappus of *Centaurea*. Barbellulate is used when the roughness of the pappus is caused by extremely short points, as in *Aster*.

Barbels. Small cylindrical vermiform processes appended to the mouth of certain fishes, and subservient to the sense of touch.

Barber (Fr. *barbier*, from Lat. *barba*, a beard). A person who makes a trade of shaving and dressing the hair of other people for money. If we believe Varro (Plin. vii. 56), it was not until the 454th year of the city that Ticinius Mena first imported barbers into Rome from Sicily. Their shops (Tonstrinae) soon became the resort of fashionable loungers and idlers; and Horace, to indicate the extreme notoriety of a story, says that it was 'omnibus notum tonsoribus.' Even the poorest citizens, according to the same author, sought refuge from their ennui in making a round of the barbers' shops:

Mutat conacula, lectos,
Balnea, tonsoras.

That the Romans paid great attention to this department of the toilet, is obvious from the ridicule that was excited against any citizen whose hair bore marks of being cut 'inæquali tonsore' (by a bungling barber).

But besides shaving the beard, to the barbers of the Romans was assigned the delicate task of trimming the nails. Hence Plautus, *Aulul.* ii. 4. 33: 'Quin ipsi pridem tonsor unguis demperat;' and Tibullus, i. 8. 11:

Quid ungues
Artificis doctâ subscissile manu?

As early as the time of Hippocrates, some surgical operations were considered degrading to physicians, and consequently fell to be performed by barbers. In France the council of Tours, in the year 1163, prohibited the clergy, who then shared with the Jews the practice of medicine in Christian Europe, from performing any bloody operation; and from that time the barbers remained for some centuries in uninterrupted possession of the practice of surgery. In England also, early in the sixteenth century, the barbers were incorporated with the surgeons of London (32 Hen. VIII. c. 42); but at the commencement of last century, when a new impulse was given to the science

BARGE

of surgery, the barbers were deprived of their honourable association with surgeons. (18 Geo. II. c. 15.) In Holland and Germany to this day the barbers are wont to wield the lancet and the razor alternately. In these countries the business of haircutting is carried on, not by the barbers, but by a distinct and superior class, the *friseurs*. The barber's pole has given rise to many speculations and ingenious absurdities. The fact is, that the pole was the distinguishing characteristic of a few only, indicating on the part of him who possessed it surgical as well as tonsorial ability. (For some curious remarks on the barbers of Edinburgh, vide *Creech's Statistical Account of Edinburgh*.)

Barberry. [BARBERRY.]

Barbette (Fr.). In Military language, guns are said to be mounted in barbette when they are raised so as to fire over a parapet, instead of through embrasures, by which means they have a wider sweep.

Barbican (Ital. *barbacane*, A.-Sax. *barbacan*). A watch tower for the purpose of despoiling the enemy; also the outer work or defence of a castle, or the fort at the entrance of a bridge. Apertures in the walls of a fortress for firing through upon the enemy are also called barbicans. Mr. Wedgwood (*Dictionary of English Etymology*) regards the word as a corruption of the Persian *bâla khaneh*, an upper chamber.

Barbiton (Gr.). An ancient musical instrument, somewhat resembling the lyre.

Barbula (Lat. dim. of *barba*, a beard). A finely divided beard-like apex to the peristome of some mosses, as in the genus *Tortula*.

Barcarolle (Ital. *barcarola*). A song sung by the Venetian gondoliers.

Bards (Welsh, *bardd*). The ancient poets of the Celtic tribes are so termed by the Roman writers, who speak of them as the priests as well as the instructors of these tribes. Lucan expressly mentions the doctrine of the immortality of the soul as one of their most characteristic tenets. After the introduction of Christianity the importance of the bards in society diminished; but in Wales, Ireland, and other Celtic districts, they continued to be held in much honour. The most ancient compositions of Welsh bards which we possess (those of Taliessin, Aneurin, and Llywarch) are supposed to be of the sixth century.

Bare Poles. The masts without any sails upon them, the ship being at sea. Under bare poles, in general, implies that the wind is so high that no sail can be exposed to it.

Bargain. [CONTRACT.]

Bargain and Sale. In Law, a species of contract through which (and by means of the Statute of Uses) realty became vested in the purchaser.

Barge (Low Lat. *barga*). A general name given to flat-bottomed craft of a certain size employed on rivers and canals. Also one of the larger boats of a man-of-war, between 30 and 40 feet long. Barge is also a general term for boats of state or pleasure.

BARGE BOARDS

Barge Boards. In Architecture, the inclined projecting boards placed at the gable of a building, which hide the ends of the horizontal timbers of a roof, and are frequently carved with trefoils, quatrefoils, flowers, and other ornaments.

Barge Course. In Architecture, that part of the tiling of a roof which projects beyond the external face of the gable of a building.

Barilla. The name given in commerce to the impure carbonate of soda, imported from Spain and the Levant. It is made by burning certain plants that grow upon the seashore, especially the *salsole* soda, to ashes, which are fused into grey porous masses. For an account of the places where it is produced, the quantities shipped from them, and the uses to which it is applied, see M'Culloch's *Commercial Dictionary*.

Baritone or Barytone (Gr. *Baptrivos*) In Music, a high bass, sung by a male voice, the compass of which is between tenor and bass. In ancient church music it was written with the F clef on the third line of the staff. By the French, the baritone is called *basse-taille*.

Barium. The metallic base of baryta; it is of a grey colour, more than twice as heavy as water, and is instantly oxydised by air and by water. [BARYTA.]

Bark or Barque (Low Lat. *barca*). term applied rather vaguely to square-rigged merchant vessels. A bark has three masts which do not rake; but beyond this there appears to be no special mark to distinguish it from any other large merchantman. A bark, however, is never a steamer.

BARK (Icelandic, *börkr*). The exterior covering of the trunk of a tree. It is composed of cellular tissue, traversed by woody tissue passing down it longitudinally, and connected with the medullary processes of the wood. It is increased in trees by annual layers formed on its inner face, and gradually perishes on the outside as it is distended by the growth of the interior. It seldom, however, shows any very distinct trace of concentric circles, because the latter are continually displaced and disturbed by its distension. Its inner face is named liber. At the commencement of the annual growth of a tree, it separates spontaneously from the wood, in order to make room for the new matter forming beneath it. It is the depository of many of the secretions of plants, and seems to act as a living filter of a curious kind, separating certain secretions from others, and allowing a part only to pass off horizontally in the medullary processes on their way to the centre of the tree. Its use is to act as a protector to the wood, and as the channel of the sap in its descent from the leaves. Its fibre is often tenacious, and manufactured into linen or cordage. True bark only exists in Exogens and Gymnosperms; in Endogens its place is supplied by a cortical integument, which cannot be separated from the subjacent wood without violence.

The bark of many plants is employed for

BARNACLE GEESE

medicinal or economic purposes. Of medicinal barks, that known as Peruvian or Cinchona Bark, the produce of various species of *Cinchona* and the source of quinine, stands pre-eminent. Among other important kinds are *Angostura* Bark, the febrifugal bark of *Galipea cusparia*; *Canella* Bark, a stimulant aromatic bark obtained from *Canella alba*; *Cascarilla* Bark, the aromatic bark of *Croton Cascarilla* and other species; *Quercitron* Bark, the yellow dye bark of *Quercus tinctoria*; *Oak* Bark, the valuable tanning bark of the common oak; *Winter's Bark*, the tonic aromatic bark of *Drimys Winteri*; and *Worm Bark*, the anthelmintic bark of *Andira inermis*.

BARK, PERUVIAN. [CINCHONA.]

BARK, USE OF, IN TANNING. [TANNER'S BARK.]

Bark Stove. A glazed structure for tropical plants, in which there is a bed of tanners' bark, or of some other fermentable material, which will produce a moist heat. The use of bark is now, however, often superseded by hot water, distributed either in pipes or tanks beneath the bed in which the plants are placed.

Barking Irons. Instruments for removing the bark of oak and other trees, which is used for tanning. They consist of a blade or knife for cutting the bark, while yet on the trunk, across at regular distances, and of chisels or spatulæ, of different lengths and breadths, for separating the bark from the wood.

Barley. *Hordeum* is a genus of Grasses, characterised by an imbricated-spiked inflorescence, consisting of one-flowered spikelets in twos or threes. To this belongs Barley, a bread corn of considerable importance. Its native country is unknown, some ascribing it to Tartary, others to Siberia. In Spain and Sicily it produces two crops in the year; but in countries as far north as Britain it produces only one, and is rather a delicate species of grain. In England it is second in importance to wheat. It is a most valuable crop in the rotation best adapted to light or turnip soils, which, from that circumstance, are sometimes called barley lands. Where its culture is best understood, as in Norfolk, it is generally preceded by turnips or other green crops. There are two leading species of this grain in cultivation—the *Hordeum distichon*, two-rowed or Common Barley; and the *Hordeum hexastichon*, or Six-rowed Barley. One of the best known varieties of the latter, and the only one in common cultivation in Scotland, is called *Bere* or *Bigg*. It is not now used as a bread corn; but it is used very extensively in malting, and in the fattening of cattle, hogs, and poultry. The crops differ very widely, according to the land and the season, varying from 36 to 64 bushels an acre; but the most usual crop is from 36 to 50 bushels. The common weight of barley is 60 or 64 lbs. per Winchester bushel.

(A.-Sax. *beorma*). [YEAST.]

Barnacle Geese. It was a popular superstition during the middle ages, and even down

BARNACLES

to the end of the seventeenth century, that the birds known by this name were produced from shells found on certain trees in Scotland and its off-lying islands. To account for this supposed fact, the most absurd explanations were given by such writers as Giraldu Cambrensis, Hector Boece, and John Gerard. There can be little doubt that the fable or myth arose from a confusion of sound with the name of the Cirriped [which see], the original name of the bird being *Hibernica*, or *Hibernicula*, from *Hibernia* or Ireland, where they were chiefly found. By dropping the first syllable, the word became *Bernicula*, and then passed into the form *Barnacle*. (Max Müller, *Lectures on Language*, 2nd series, p. 550.)

Barnacles (most probably from the late Latin *pernacula*, diminutive of *perna*, a ham, from a supposed resemblance to a leg of pork). [CIRRIPEDS.]

BARNACLES. A colloquial word, employed to signify *spectacles*. The etymology of the term is a subject of controversy. It is regarded by Dr. Latham as being, like *binnacle*, a corruption from *Binocle* [which see]. By Professor Max Müller it is connected with the German *Brille*, which in a vocabulary of 1482 occurs in the form *Bernlein*, this word being a corruption of *beryllus*. (*Lectures on the Science of Language*, 2nd series, p. 534.)

Barnhardtite. A double sulphide of copper and iron, with traces of silver. It occurs massive, of a pale bronze-yellow colour, like that of *Pyrites*, but with less lustre, in a mine in Cabarras co. North Carolina.

Baerolite (Gr. *Bapús*, heavy, and *λίθος*, stone). A name given to carbonate of baryta, or *Witherite*, in consequence of its high specific gravity. [BARIUM, BARYTA.]

Barometer (Gr. *Bápos*, weight, and *μέτρον*, measure). A well-known instrument, invented by Torricelli, for measuring the weight or pressure of the atmosphere.

Fig. 1 represents the *Cistern Barometer*, the most simple form of the instrument. It consists of a glass tube about 34 inches long, which must be filled with mercury, and inverted in a cistern containing the same metal. When placed in the cistern, the mercury sinks till the column between the two surfaces *m* and *n* just counterbalances the pressure of the air. The space above the mercury, *a m*, is or ought to be a perfect vacuum (except as to the presence of the vapour of mercury). In this barometer, as the diameter of the cistern is generally very much greater than that of the tube, almost the whole effect of the rise or fall is perceived in the variation of the upper surface at *m*. For supposing the section of the cistern 20 times greater than that of the tube, and that the height of the column *m n* suffers a diminution of one inch; it is evident that, as all the mercury which goes out of the tube passes into the cistern, when it falls at *m* it must rise at *n*, but less in proportion as the section of the cistern exceeds that of the tube. In the case supposed, therefore, the alteration of the level

BAROMETER

at *m* will be 20 times greater than at *n*; that is to say, there will be a fall of $\frac{19}{20}$ of an inch at *m*, and a rise of $\frac{1}{20}$ of an inch at *n*.

Fig. 2 is the *Siphon Barometer*, which was also proposed by Torricelli, as being more convenient than the former. It is merely a tube hermetically sealed at the upper end, having the lower or open end bent upwards in the form of a siphon. The variations in this are only half as great as in the cistern barometer; for the tube being of the same width throughout, a diminution of the column *m n* amounting to one inch will be marked by a fall of half an inch at *m* and a rise of half an inch at *n*. This inconvenience may, however, be remedied by having the lower branch blown into a wide bulb; but as it is very difficult to procure the bulb to be blown into a perfectly regular shape, this enlargement of the bulb is found to give rise to inaccuracies.

Fig. 3 is a barometer suggested by Descartes, and executed by Huygens, in which the sensibility is greatly increased. Two tubes are cemented to the opposite ends of a pretty wide cylinder, *b c*. The lower tube and a portion of the cylinder, *c p*, are filled with mercury; above which water or spirit of wine is introduced, reaching to the top of the upper tube, which is hermetically sealed. The vacuum is made, as in the Torricellian barometer, by inverting the compound tube in a basin of mercury. The enlargement of the scale obtained

by this construction is found thus: Suppose the horizontal section of the cylinder, *b c*, to be 10 times that of the tube, and the specific gravity of mercury 14 times that of water. Let *x* be the fall of the mercury in the cylinder at *p*, corresponding to a fall of one inch of the common Torricellian barometer. The descent of the water *x* inches at *p*, will be marked by a descent of $10x$ inches in the tube at *m*. But the diminution of the height of the column of water must correspond to a diminution of $(1-x)$ inches in the height of the column of mercury of equal weight with the water; therefore, the diminution of the column of water is $14(1-x)$ inches. Hence, $10x = 14(1-x)$, or $x = \frac{14}{24}$, and the descent of the water at *m* = $\frac{14}{24} = 5\frac{7}{12}$; that is to say, when the Torricellian barometer falls one inch, the barometer of Descartes falls $5\frac{7}{12}$ inches. The defect of this construction is, that the air contained in the water escapes into the vacuum above, and destroys the accuracy of the instrument.

BAROMETER

The volatility of the upper liquid also causes the instrument to be affected by changes of temperature. theory of Mr. Ivory. (*Encyclopædia Britannica*, art. 'Capillary Action.')

Fig. 4 is the *Wheel Barometer*, proposed by Hooke. A small weight floats on the surface of the mercury in a siphon barometer, which is very nearly counterpoised by another weight, *w*, connected with the former by a string passing over a pulley, *p*. When the mercury rises at *n*, the weight *w* descends, and turns the pulley. An index attached to the axle of the pulley shows on a dial the quantity of revolution. This barometer, though not an accurate instrument, is perhaps the most useful form for general observations, where fluctuations rather than absolute measurements are of most importance.

None of the contrivances which have been described for increasing the range of the oscillations have been found to succeed well in practice. It is found to be decidedly better to apply minute divisions, than to attempt to enlarge the scale: accordingly, experimenters now adhere to one or other of the two ancient forms, the cistern barometer and the siphon barometer. The height of the column in the siphon barometer is conveniently measured by a movable scale attached to the frame which supports the tube. By means of a tangent screw, the scale is raised or lowered till its zero coincides exactly with the surface of the mercury in the lower branch; and with the assistance of a vernier, the height can be read off to the hundredth or two-hundredth of an inch with sufficient precision. The scale of the cistern barometer is usually fixed, and the bottom of the cistern is raised or lowered by a screw till the surface of the mercury in it coincides with the zero of the scale; but the scale may be movable, and its zero brought to coincide with the surface of the mercury in the basin, as in the former case. In order to determine when this coincidence takes place, recourse may be had to various expedients. The most usual is to place on the surface of the mercury a float carrying a vertical needle, some point on which answers to a fixed point on the scale, and the coincidence obtains when the two points are brought into the same level. Another contrivance to effect the same purpose was employed by Fortin, a celebrated French artist. An ivory needle is attached to the scale, pointing downwards, and having its point exactly in the same level with the zero of the scale. The image of the needle is clearly reflected from the surface of the mercury in the cistern, and the cistern is raised or lowered till the point of the needle and its image precisely coincide.

Corrections necessary.—In all barometric observations there are, in general, two essential corrections to be made; one for the capillarity or depression of the mercury in the tube, and the other for temperature. Pure mercury in a glass tube always assumes a convex surface. The following are the corrections for tubes of different diameters, according to the

Diameter of Tube Inches	Depression Inches	Diameter of Tube Inches	Depression Inches
.10	.1403	.40	.0153
.15	.0863	.45	.0112
.20	.0581	.50	.0083
.25	.0407	.60	.0044
.30	.0292	.70	.0023
.35	.0211	.80	.0012

These corrections, which must always be applied to cistern barometers, show that wide tubes ought to be preferred; in fact, when the diameter of the tube exceeds half an inch, they may be safely omitted. In siphon barometers having both branches of the same diameter, the depression is equal at both ends; consequently the effect is destroyed, and no correction is required. This is a considerable advantage; for notwithstanding the most elaborate calculations, some uncertainty must always remain with regard to the exact amount of the capillary expulsion.

The correction for the temperature, which is the most important, depends on the expansion of the mercury, and the expansion of the scale in which the divisions are marked.

The expansion of mercury in bulk is 0001001 for each degree Fahrenheit. The scale is generally of some mixed metal of which the expansion is not very well ascertained: supposing it to be equal to that of copper, the expansion would be .0000096; therefore it will be sufficiently accurate to neglect the temperature of the scale, and assume that of the mercury to be .0001. Hence the following practical rule for reducing an observed height to the corresponding height at the temperature of the freezing point: 'Subtract the ten-thousandth part of the observed altitude for every degree of Fahrenheit above 32.' Suppose the thermometer 54° and the barometer 30 inches, the correction will be $(54 - 32) \times 30 \times .0001 = .066$, to be subtracted from 30 inches. In order to find the value of this correction a thermometer must be attached to the barometer, and observed at the same time. A table, showing the correction for temperature for every degree of Fahrenheit from 30° to 90°, and for every difference of half an inch in the height of the mercury from 28 to 30.5 inches, was constructed by Professor Schumacher, and is given by Mr. Bailey in the *Phil. Trans.* for 1837, p. 434.

Cause of the Variations of the Barometer.—Various theories have been proposed to account for those frequent atmospheric changes which cause the rise and fall of the barometer, but none of them can be regarded as very satisfactory. Whatever tends to increase or diminish the vertical pressure will obviously cause the barometer to rise or fall. During the prevalence of northerly and easterly winds the barometer stands high, whilst winds from the opposite quarters are almost universally

BAROMETZ

accompanied by a depression of the mercurial column.

Uses of the Barometer.—The barometer is an instrument of great importance in astronomy, its indications forming an essential element in determining the amount of atmospherical refraction. [REFRACTION.] It is also, on account of its application to the measurement of altitudes, indispensable in all researches connected with climate. [HEIGHTS, MEASUREMENT OF.]

To the chemist also it is an invaluable instrument in the analysis and investigation of gaseous bodies. The purpose for which it is most commonly resorted to is to prognosticate the state of the weather. On land this is perhaps the least important of its applications, but the case is widely different at sea.

No certain rules can be laid down for prognosticating the state of the weather from the barometer. It is always to be remembered that what the barometer actually shows is the present pressure of the atmosphere, and that its variations correspond to atmospherical changes which have already taken place, and the effects of which may follow their cause at a greater or less interval.

Nevertheless in the hands of Admiral Fitzroy the barometer, when supplemented by other meteorological observations, has proved a most valuable instrument for the prognostication of storms, and it is not improbable that any considerable motion in the air and the direction of that motion will ere long be capable of infallible prediction. [ANEROID BAROMETER.]

Barometz. The hairy stem of *Cibotium Barometz*, a species of fern which, from its procumbent position and shaggy surface, looks like a crouching animal; hence called Scythian lamb.

Baron. A title common to most European nobility, the German 'Freiherr' being held equivalent. In this country the lowest rank of the peerage. The dignity appears to have been originally territorial. The higher feudatories of England, after the Norman Conquest, possessed baronies on which a certain number of knights' fees were dependent, and were bound to attend the king with a certain retinue of knights. But in process of time, many of the barons having lost by alienation great part of their lands, the distinction between *greater* and *lesser* barons began to arise; and the former alone constituted part of the great council of the sovereign, in their own right, until at some early period (supposed to have been about the reign of Henry III.) the practice of summoning individuals to parliament by the king's writ prevailed over the former usage. But this subject is involved in great uncertainty. It has, however, been very generally supposed that the dignity of baron, together with the right to sit in parliament, was at an early period annexed in many instances to the possession of certain lands or castles, which have thus been believed to confer *baronies by tenure*. But Sir Harris Nicolas, in his *Introduction to the*

BARONET

Peerage, gives strong reasons to show, in the first place, that it is by no means clear that persons seized of lands *per baroniam* were entitled to a summons to parliament in the reign of Edward the First; and, in the next place, that there is no positive proof of such a tenure having been legitimately established at any subsequent period. *Baronies by writ* were created by the king's writ of summons to parliament, when addressed to individuals by name. The first thus created were in 49 Henry III., of which two (Le Despencer and De Ros) exist at the present day. Whether, however, the dignity thus created was originally hereditary, admits of a doubt: no words to that effect are found in the ancient writs. But, in point of fact, the next heir was summoned by writ, after the decease of his ancestor, in a great majority of instances; and it has been long settled, that a summons to parliament by the king's writ, addressed to an individual, creates a barony descendible to heirs general. The earliest creation of a *barony by letters patent* took place in the 11th year of Richard II. (that of Beauchamp of Kidderminster); and therefore when a dignity of earlier creation than that year is claimed, it is presumed to have originated in a summons by writ, and consequently to be descendible to heirs general. On the death of a baron by writ without issue male, but with more daughters than one, the barony falls into *abeyance* until only one daughter or the sole heir of one daughter survives. The word Baron (*baro*, or *varo*, which seems to be radically the same with the Latin *vir*, Gothic *vair*, Anglo-Saxon *wer*, a man) appears to have simply signified 'man,' and in some cases freeman or citizen, in the laws of the Franks and other early nations. In France, the title of baron originally belonged only to those who were immediate vassals of the crown: it afterwards became applied in common usage to those who had the right of executing justice on their fiefs. The title of baron ranked, as in England, after those of duke, marquis, count, and viscount; except in Dauphiné and Brittany, where the baron had precedence of the three latter. In Germany the title of baron (*Freyherr*) is extremely common; but a great distinction existed, under the Empire, between the barons who were created by sovereign lords, and the barons of the Empire, the former being those immediate lords who had no voice in the Diet.

Baronet or Knight Baronet. The lowest degree of hereditary dignity in England. This order was instituted by King James I. in 1611, as a reward for the services of those who came forward to quell the insurrection in Ireland, and especially in the province of Ulster; each person who received it furnishing a supply sufficient to maintain thirty soldiers for three years. The creation is by patent under the great seal, and generally limited to the heirs male of the body of the grantee, although sometimes otherwise entailed. Baronets rank among themselves according to creation, and come next after the younger sons of barons.

BARONS OF EXCHEQUER

By a clause in the patent of creation, the heir male apparent to the title can claim the honour of knighthood, on attaining the age of twenty-one, in the life of his father or grandfather. Baronets bear for distinction on their paternal coats the arms of Ulster, in a sinister hand, erect, open, and couped at the wrist, gules in a field argent. This augmentation is placed sometimes in the middle chief point, sometimes on the less point, &c. as may be most convenient, but subject to certain rules of heraldry. Baronets of Ireland were instituted by James I. nine years after the creation of baronets in England, with similar privileges and badge. Baronets of Scotland, or Nova Scotia baronets, were created by Charles I. in 1625, in furtherance of a project of colonisation in that part of America. Their badge is the ensign of Nova Scotia. It had long fallen into disuse; but was borne again in 1775, by way of revival of the order.

Barons of Exchequer. The Judges of the Court of Exchequer are so called. Selden conjectures them 'to have been antiently made out of such as were barons of the kingdom or parliamentary barons, and thence to have derived their name.' (3 Blackstone's *Commentaries*, 45.) [EXCHEQUER.]

Barony. A territorial subdivision in Ireland, which nearly corresponds with the hundred in England. Each barony is supposed to have been originally the district of a native chief. There are in all 252 baronies in Ireland.

Baroscope (Gr. *βάρος*, weight, and *σκοπέω*, I observe). A term which has been sometimes given to the barometer. According to its derivation it signifies *observer of weight*, and is properly applied to instruments which indicate variations in the weight of the atmosphere, without giving the means of absolutely measuring it. The wheel barometer of Hooke is properly a baroscope.

Baroselenite (Gr. *βάρύς*, heavy, and Selenite). A mineralogical name applied to *sulphate of baryta*, or Heavy Spar, from its high specific gravity, and the resemblance which its crystals sometimes bear to those of Selenite.

Barosma (Gr. *βάρύς*, heavy, and *δομή*, smell). A genus of *Rutaceæ*, furnishing the medicinal Bucku leaves, which are produced chiefly by *B. crenata* and *serratifolia*, dwarf evergreen shrubs with small dotted leaves having a strong rue-like odour, and natives of the Cape of Good Hope. The leaves are used by the Hottentots as perfume.

Barrack (perhaps: from Gael. *barrachad*, a booth, from *barrach*, brushwood). A place for soldiers to lodge in, especially in garrisons. Barracks were built under the authority of the Board of Ordnance down to the year 1792, when they were placed in charge of the deputy-adjutant-general. After some further changes, the superintendence of barracks reverted, in 1834, to the Master-General of Ordnance. On the abolition of that office,

BARRIER TREATY

they came under the control of the War Department.

Barrack Master. An officer at each of the principal military stations, whose duties consist of the superintendence of barracks, and their allotment to the various troops at the station. He is responsible to the War Department.

Barras. The resin which exudes from wounds made in the bark of fir-trees.

Barratry (Old Fr. *bareter*, to deceive). A name applied by our law and that of other countries to various offences. In England, a 'common barrater' is defined by Lord Coke to be a common mover and maintainer of suits in disturbance of the peace, and in taking and detaining the possession of houses and lands or goods by false inventions. Barratry, in this sense, is an indictable offence at common law. The obtaining benefices at Rome was also an offence of *barratry*. In Maritime Insurance, barratry is any act of the master or mariners of a criminal nature, or grossly negligent, tending to their own benefit or to the prejudice of the owner of the ship, and without his permission. In Scotland, the crime of a judge who receives a bribe for judgment is called *barratry*.

Barrel (Fr. *baril*, Span. *barrila*). An English measure of capacity, varying with the nature of the liquid measured. In the old measures, a barrel denoted 31½ gallons of wine, 32 gallons of ale, or 36 gallons of beer. By a statute of 1 Wm. & Mary the ale and beer barrels were equalised for every part of England except London, and ordered to contain 34 gallons. The term Barrel was formerly in use, too, as a measure of other sorts of goods. Thus, a barrel of salmon, 42 gallons; a barrel of soap, 256 pounds. In common language any hollow cylinder is called a barrel.

BARREL. In a built-up cannon, the inner tube is called the barrel. This is the most important part of the gun, as it has to receive the greatest strain of the discharge. [GUN.]

Barren Flowers. Those flowers which either have stamens and no pistil, or which have neither stamens nor pistil.

Barricade (Fr., from *barre*, a bar). A defence, either by intrenchment or raised work, made, in a hasty manner, by barrels filled with earth, heaps of stones piled up, carts, trunks of trees, or any other materials which would obstruct the passage or advance of an opposing force. The famous day of the barricades at Paris took place on the 12th of May, 1688, when the populace invested the troops of Henry III., in the Louvre, and forced him to escape from Paris. The barricades again formed an important feature in the revolutions of July 1830, and Feb. 1848.

Barrier (Fr. *barrière*). A strong wood palisade or paling erected to defend the entrance of a passage into a fortified place or intrenchment. The gate has a movable bar.

Barrier Treaty. In 1713, a negotiation concluded between the Dutch and the king of France shortly before the peace of Utrecht, by which the former reserved the right to hold

garrisons in certain fortresses of the Spanish Netherlands.

Barringtoniaceæ (*Barringtonia*, one of the genera). A small natural order of perigynous Exogens, related to the *Myrtaceæ*, and consisting of trees or shrubs inhabiting the tropics of the New and Old World. Several of the species are plants of great beauty; and the bark of some species of *Barringtonia* possesses narcotic qualities.

Barris. A large baboon of the Guinea coast.

Barrister. An advocate admitted to plead 'at the bar' (that is to say, without the bar, if an 'outer' barrister, popularly called 'stuff gown'; within, if a king's counsel or sergeant) in the English courts of common law and equity. Barristers were anciently styled apprentices at law, until their admission to the degree of sergeant. A student intending to be called to the bar must be admitted a member of one of the four Inns of Court (Inner and Middle Temple, Lincoln's Inn, and Gray's Inn), and reside for a certain time, during three years in some cases and five in others. The disputations or arguments (termed exercises) which were formerly required of a student have been reduced to mere matters of form, and a system of examinations in the Inns of Court has been substituted. The power to 'disbar,' or exclude a barrister from practice, is vested in the Benchers of the Inns, subject to appeal to the Judges. A barrister has no legal mode of recovering fees for his services.

Barrow (A.-Sax. beorg, beorh, *a mound*). An artificial hillock, designed to receive the bodies of the dead. The cairns of Scotland are constructed only of stones, and are almost exclusively confined to that country. The use of barrows seems to have been general in the earliest times. The barrow, raised over the Athenian dead, may still be seen on the field of Marathon. Herodotus, i. 93, describes a Lydian barrow, of which the base was formed of stones, the upper part consisting of a mound of earth. Barrows are found scattered over the plains of the Ukraine and of Tartary, and in great numbers in the Mississippi valley of North America. The barrows of England are supposed to be almost all of British construction, although the mounds properly so called are sometimes confounded with the tumuli found in Roman camps, where they serve as land marks, or for some military purpose. Barrows have been distinguished, according to peculiarities of form and construction, into long barrows, bowl, bell, pond, twin, cone, broad, &c. In the most ancient barrows, the bodies found are deposited within a cist or stone receptacle, with the head towards the north: in those of later date, this direction is not observed. The bones which have been discovered within the numerous barrows that have been opened were generally accompanied by utensils, weapons, &c.; and from the form and finish of these, some conjecture has been made as to the period of the interment. But these barrows, although generally sepulchral, are not uniformly

so: in some, bones of animals only have been found. Barrow burial is said by Sir R. Hoare to have lasted from a period of unknown antiquity down to about the eighth century. (Gough, *Sepulchral Monuments*; Worsæe, *Scandinavian Antiquities*.)

Barsowite. A felspathic mineral occurring in boulders in the auriferous sand of Barsowskoi in the Ural, as the gangue of blue Corundum. It is massive, of a snow-white colour, and has a more or less pearly lustre.

Barter (Old Fr. bareter, *to deceive*, from the haggling of those who make bargains). A rule of Arithmetic by which the values of commodities of different kinds are compared.

Barton Clay. The name given to a somewhat important division (rich in fossils) of the middle Eocene tertiary rocks of the south-east of England. They are compact clays of a dark brownish-grey colour, with large bands of septaria. They are developed to a thickness of 350 feet on the cliffs of the coast of Hampshire, and include certain silicious sands at the base of Headdon Hill and the top of Barton Cliff. The sands are less than 50 feet thick in some places and upwards of 250 feet in others. The Barton series correspond with the *sables moyens* of French geologists. They are rich in characteristic fossils.

Barycentric Calculus. An application to Geometry of the mechanical theory of the centre of gravity. This has been done in two distinct ways, according as *metrical* or *descriptive* geometrical properties were to be investigated. The mechanical quadrature of the Parabola by Archimedes, as also the methods given by Pappus for determining the surface and volume of a solid of revolution [GULDIN'S RULES] are examples of applications of the first kind. The barycentric calculus as at present understood, however, is of modern origin and devoted exclusively to the investigation of descriptive properties of figures. It has been developed almost entirely by Möbius, the present professor of astronomy at Leipzig. His work on the subject (*Der barycentrische Calcul*) was published in 1827, and contains the germ of the present powerful methods of trilinear and quadriplanar coordinates, by which, indeed, it has been superseded. The method of the calculus consists in defining a point as the centre of gravity of certain fixed points, to which coefficients or weights are ascribed. As long as the *relative* magnitudes of these coefficients is preserved, the point remains fixed; but when the coefficients are regarded as functions of one or more independent variables the point is restricted to a certain locus, which latter is, of course, characterised by the forms of those functions. The barycentric calculus has an algorithm of its own. For instance, the symbolical congruence

$$aA + bB \equiv S$$

denotes that the points *A*, *B*, and *S* are in a right line, and that the last divides the line *AB* into segments *BS*, *SA* proportional to the numerical coefficients *a*, *b*.

BARYSTRONTIANITE

Barystrontianite. A mechanical mixture of the sulphates of baryta and strontia, found in yellowish-white aggregations with a dull pearly lustre at an old lead mine on Mainland, one of the Orkneys, and on the beach at the Point of Ness.

Baryta (Gr. *βαρύς*, heavy). The oxide of barium, composed of 69 barium and 8 oxygen; its equivalent, therefore, is 77. Baryta is an alkaline earth, of a grey colour, not easily fusible, and poisonous. It is soluble in about 20 parts of cold water. It forms white salts with the acids, all of which are poisonous except the sulphate. The soluble salts of baryta are excellent tests of the presence of sulphuric acid, which they indicate in solution by a white precipitate, insoluble in water and in acids, and composed of 77 baryta and 40 sulphuric acid; 117 parts, therefore, of pure and dry sulphate of baryta are equivalent to 40 of sulphuric acid. There are only two abundant natural compounds of baryta: the sulphate, which occurs crystalline, and the carbonate. Native sulphate of baryta, heavy spar, or *baro-selenite*, is found in Cumberland and Westmoreland; a variety from Derbyshire is provincially called *cawk*. Native carbonate of baryta, or *barokite*, was first discovered at Anglesark in Lancashire by Dr. Withering, and hence called *Witherite*. It occurs crystallised and massive. It consists of 77 baryta and 22 carbonic acid; its equivalent, therefore, is 99.

Baryto-cselestin. A crystallised compound of the sulphates of baryta and strontia, found in Canada and in Switzerland.

Baryto-calcite. A mineral consisting of 66·3 per cent. of carbonate of baryta, and 33·7 of carbonate of lime. It occurs in veins in Mountain Limestone, both massive and in semi-transparent greyish-white crystals, at Alston Moor in Cumberland.

Barytone (Gr. *βαρυτόνος*, deep-sounding). The male voice, the compass of which is between tenor and bass. Also a musical instrument similar to the *viol di gamba*.

Basalt. A term vaguely applied to many varieties of rock once ejected from volcanoes and now spread over the earth, or contained within the walls of a vein or dyke. Basalt is often columnar, having in the act of cooling separated into spheroids, these again breaking up into groups of imperfect six-sided columns.

The island of Staffa is one of the most celebrated basaltic monuments of the world: it is about a mile and a half in circumference; and its greatest elevation, which is upon its north-west side, is about 144 feet. Its lowermost bed upon that side is a basaltic conglomerate. The columns are compact and uniform in texture, dark greyish-black interiorly, and rusty brown where exposed to the weather. Amorphous and columnar basalt, and a stratum of pebbles foreign to the island, form its upper portion.

Fingal's Cave is justly considered as the most beautiful of ocean caverns, and owes its existence to the circumstance of the columns

BASALT

being jointed in that place, while their general character is to be without divisions; hence the successful invasion of the waves in this particular quarter. The entrance is

FINGAL'S CAVE.

70 feet high, and resembles a Gothic arch; the width 40 to 50 feet; the length 227 feet. Its interior preserves a considerable degree of regularity throughout, its sides being columnar, and in many places broken and irregularly grouped, so as to catch a variety of direct and reflected tints, mixed with unexpected shadows, and producing a picturesque effect which no regularity could have conferred. The sea never entirely ebbs out of this cave, but the broken range of columns which forms the exterior causeway is continued on each side within it. 'This cave,' says Dr. McCulloch, 'has been frequently described, but no description is adequate to the representation of its varied beauties and singular associations. If it were even destitute of that order and symmetry, that richness arising from multiplicity of parts combined with greatness of dimensions and simplicity of style which it possesses—still the prolonged length, the twilight gloom half concealing the playful and varying effect of reflected light, the echo of the measured surge as it rises and falls, the pellucid green of the water, and the profound and fairy solitude of the whole scene, could never fail strongly to impress any mind alive to the wonders and beauties of nature.' Mackinnon's Cave and the Boat Cave, in the same island, are also worthy the traveller's attention.

The Giant's Causeway, and the various promontories of the coast of Antrim, form another basaltic district of great grandeur and interest. The Causeway itself consists of three piers of columns, which extend into the sea, and are walled round as it were by precipitous rocks from 200 to 400 feet high, in which are several striking columnar assemblages, vertical, inclined, curved, and horizontal, and in some places appearing as if wedged or driven into the surface of the precipice: Bengora, which bounds the Causeway on the east, consists of alternate ranges of tabular and massive with columnar basalt: Pleskin presents several colonnades of great height and regularity, separated from each other by tabular basalt; and at Fairhead there is a range of columns from 200 to nearly 300 feet in height, supported by a steep declivity, which forms a terrace nearly 60 feet above the level of the sea beneath.

Sometimes basalt rises in massive and abrupt rocks, assuming the appearance of a uniform homogeneous substance, and scarcely exhibiting any of the columnar regularity which we have just had occasion to admire in Staffa and the Causeway. The castles of Dumbarton, Edinburgh, and Stirling are built upon such masses. At other times

BASANITE

forms low, rugged, and unpicturesque strata; sometimes remarkably bent, but without decided columns.

Good examples of columnar basalt are seen on the banks of the Rhine, between Bonn and Coblenz. Tabular basalt is very largely developed in India and again in Asia Minor.

Basalt is confined to no geological age and to no country; but the older specimens, where the rock is not columnar and where there are sheets poured out upon the surface, are more usually spoken of as greenstone.

The components of basalt are silica and alumina, with variable proportions of lime, magnesia, soda, potassa, and oxide of iron, the proportions differing greatly in the several varieties.

Basanite (Gr. *βασανίτης*, the touchstone). A variety of silicious slate, sometimes used as a touchstone to determine the purity of gold by the colour of its streak. [LYDIAN STONE.]

Basinet or **Basinet**. A light basin-shaped helmet, worn by the infantry in the reigns of Edward II. and Edward III., and of Richard II. (Grose, *Ancient Armour*.)

Base (Gr. *βάσις*). In Architecture, this term is generally applied to the body which supports another. In the orders it is applied to the lower part of a column, moulded or plain, on which the shaft is placed. In the Grecian Doric the columns are without bases, and they stand immediately upon the floor, or pavement of the portico. The different bases are represented below, including the Attic base. In mediæval architecture the base of the columns plays an important part, and is highly characteristic of that style of art.

BASE. In Chemistry, a term chiefly applied to metallic oxides, or to the leading constituent of compounds. Thus, soda is called the base of sulphate of soda; and sodium is the metallic base of soda. Hence the distinction into salifiable and metallic bases.

BASE. In Geometry, any side upon which a figure may be supposed to rest and from which altitudes may be measured. In Geodesy, it is the right line to which all points are ultimately referred by a process of triangulation. [SURVEYING.]

Base or **Bass.** In Music, the lowest part in a concert, whether vocal or instrumental. In composition it is usually considered the fundamental or most important part, on which, as on a *base*, the superstructure is raised.

Base Clef. [CLEF.]

Base of Operations. By this term, in Military art, is meant a frontier, the course of a river, a range of forts, or any topographical or military extent of country on the imaginary line of which the corps of an army assemble: offensively, to take their departure thence into

BASILISCUS

the enemy's country, and towards which in case of failure it is intended to retreat; defensively, to counteract all the measures which an invading force may attempt.

Base, Thorough. [THOROUGH BASS.]

Basella (a Malabar word). A climbing succulent-leaved plant, native of the tropical parts of Asia, representing the *Basella*, a tribe of Chenopodiaceous plants. *B. alba* is commonly cultivated instead of spinach in the East Indies.

Basicerine. [FLUOCERINE.]

Basigynium. A stalk rising above the origin of the calyx, and bearing an ovary at its apex, as in *Capparis*.

Basil. A fragrant aromatic herbaceous plant, the *Ocimum basilicum*, a native of India, whose leaves are much used in cookery for the purpose of giving a savoury flavour to dishes.

Basilio (Gr. *βασίλικος*, royal). A pharmaceutical term, formerly applied to certain powders, ointments, &c. of pre-eminent virtues and activity.

Basilica (Gr. *βασίλική*). A name given to certain buildings which were used for the purposes of law or commerce, these uses not being in every case easily distinguished. The term may, perhaps, be derived from the Archon Basileus at Athens, who gave judgment in the *Στοὰ Βασιλείας*. It thus becomes probable that both the name and the form of the building were received by the Romans from the Greeks: and it seems certain that no building of this kind existed at Rome before B.C. 184. Originally the basilica consisted simply of an open peristyle enclosing a space which was otherwise exposed to the outer air; but in later examples the peristyle itself was enclosed by an outer wall, and thus the area became divided into three parts—the central nave (*media porticus*) being divided by two rows of columns from the aisle on either side. At one end of the nave was the tribunal of the judge, which was sometimes thrown out in a circular or apsidal form, and was then called the hemicycle. Such a plan as this is obviously capable of indefinite extension. Thus in the Basilica of Trajan the nave is flanked by a double row of columns, and consequently by two aisles on either side, while a semicircular apse is thrown out at both ends of the main body of the building. Such designs scarcely needed any change to adapt them to the purposes of Christian worship; and many of these edifices were accordingly converted into churches in the time of Constantine. The nave now served to contain the people who assembled for worship; and the tribunal of the judge gave place to seats of the bishop and presbyters which surrounded the altar. Of these buildings the church of St. John Lateran at Rome is an example.

BASILICA. In Jurisprudence, a name given to a digest of laws in sixty books, commenced by the Byzantine emperor Basilus A.D. 867, and completed A.D. 880.

Basiliscus (Gr. *βασίλισκος*). A basilisk. This term is applied in Zoology to a harmless

BASIN

genus of Saurian reptiles, of the Iguanoid family, having no femoral pores; but with palatal teeth; a covering of small scales; and an elevated dorsal crest, supported by the vertebral spines, and extending from the neck to the middle of the tail. One of the species (*Basiliscus mitratus*) supports a mitre-shaped crest on the head. Hence arose the many legends of antiquity about the supposed 'King of Serpents,' the basilisk or cockatrice, whose poison was supposed to be communicated from his eyes and breath.

Basin (Fr. bassin, Ital. basino). In Physical Geography, the space of country drained by a particular river; as the Basin of the Thames, Rhine, Rhone, &c. In Geology, the same term is applied to depressed portions of strata, forming a hollow surrounded by hills, as the 'London Basin,' the 'Paris Basin,' &c.

Basissolute (Lat. basis, and solutus, free). A name sometimes applied to those leaves which are prolonged at the base below the point of origin, as in the bracts of *Fumaria*, the leaves of *Sedum reflexum*, &c.

Basket (Welsh busged, Latinised bascauda). In Architecture, the central portion of the Corinthian capital, which emblem was supposed to have been derived from the use of a basket, surrounded by the acanthus plant, for the decoration of the capitals of this order.

Basque Language. [TURANIAN LANGUAGES.]

Bass. A miner's name for highly bituminous coal-measure shale. [BATT.]

BASS. [BASE. In Music.]

Basset. A miner's expression in some parts of England for the edges of strata as they rise or *crop* out of the earth. [OUTCROP.]

Basset Horn. In Music, a wooden wind instrument, of the hautboy tribe, playing the tenor.

Bassotto (dim. of basso). In Music, the smallest species of the bass violin. Not used in the modern orchestra.

Bassia (named after Bassi, curator of the Botanic Garden at Bologna). A tropical genus of *Sapotaceæ*, consisting of trees with entire leaves and axillary flowers. *B. butyraera* is the Indian Butter-tree, whose seeds yield a fatty substance, used to adulterate ghee. *B. Parkii* is the Shea-tree or Butter-tree of Africa, the butter of whose seeds forms an important article of commerce at Sierra Leone. *B. longifolia*, the Illupie-tree of Coromandel, and *B. latifolia*, the Madhuca-tree of Bongal, possess similar properties. Their timber is in some cases of good quality.

Basso Continuo (Ital.). In Music, the same as Thorough Bass.

Basso-rilievo or **Bas-relief**. [RILIEVO.]

Bassoon (Ital. bassone, Fr. basson). A musical wind instrument made of wood, serving as the proper bass to the oboe and clarionet. The Italians call it *fagotto*, because composed of two pieces of wood *fagotted* as it were together. It is played by means of a bent mouthpiece and reed.

BASTILLE

Bassorine. A modification of gum, originally discovered by Vanquelin in gum bassora.

Bastard (a word of uncertain origin). By the ancient legal course of precedent in England, the fact of birth during the marriage of the parents, or within a certain time after the death of the husband (extended in some cases to a great length, as in that of the Countess of Gloucester, temp. Ed. II., to one year and seven months), was conclusive in favour of legitimacy. But this fact is now held to amount only to strong presumptive evidence, repellable by proof of non-access. The legal incapacities of an illegitimate child, by the law of England, relate wholly to the powers of inheritance and succession, to which he is in no respect entitled either as to real or personal property. In case of a divorce 'à vinculo matrimonii' in the spiritual court all the children born during the coverture are bastards, because such divorce is always upon some cause that renders the marriage null from the beginning. The Scottish law is less strict in favour of legitimacy than that of England. Two species of legitimation have been adopted in it from the civil law: one, 'per subsequens matrimonium,' by the subsequent intermarriage of the parents (but a child born in Scotland, and legitimated by subsequent intermarriage in Scotland, is not entitled to succeed to real property in England; and, if born in England, remains a bastard to all intents and purposes); and, secondly, 'per rescriptum principis,' by letters of legitimation from the crown. [MARRIAGE, LAW OF.]

Bastard Stucco. Plastering of three coats, of which the first is usually composed of the *rendering coat*, or the roughing in; the second is the *floating coat*, as in trowelled stucco, and the third, or *finishing coat*, contains a small quantity of hair mixed with the lime and sand. Bastard stucco is not hand-floated, and the trowelling is done with less labour than that required for what is called trowelled stucco.

Bastard Sugar. *Bastards* is a term applied by the sugar refiners to an impure sugar chiefly produced by the action of heat and various substances used in the refining, and which cannot be remuneratively purified. They are also called *pieces*.

Bastard Tuck Pointing. An imitation of tuck pointing, which is executed by raking out the joints of brickwork, filling in with blue mortar, and pointing upon this with white mortar.

Bastard Wing (*Alula spuria*, Linn.). Three or five quill-like feathers, placed at a small joint rising at the middle part of the wing.

Bastille (Fr.). In France, in the middle ages, towers and other outworks erected without the limits of towns were so called. The famous Bastille of Paris was an edifice of the same description, originally erected outside the city, near the modern Porte Saint Antoine. It was built by Hugues Aubriot, prévôt des marchands, in 1369; and he is said to have been the first prisoner of state confined in it after it was

BASTINADO

employed for that purpose. The Bastille was taken by the people of Paris on the 14th of July, 1789, and demolished.

Bastinado (Ital. *bastonnata*, from *bastone*, a stick). An ordinary mode of punishment in Oriental countries, especially China, Turkey, and Persia. It is commonly inflicted upon the soles of the feet. According to the Turkish law, slaves and *rayahs* or tributaries alone are liable to it; but no such limitation is observed when the temper of a magistrate possessing summary authority is inflamed. This punishment is termed *zarb* in Turkish. It is extremely severe, although limited by law to the Jewish number of 39 blows, or 75 in some aggravated cases; but this regulation, like the other, is little observed in practice. (See generally, as to this species of infliction in penal law, the essay of Lanjuinais, *Sur la Bastonnade et la Flagellation pénale*.)

Bastion (Ital. *bastione*). In Fortification, the bastion consists of two flanks, serving for the defence of the adjacent curtains, and two faces, making with each other an angle of 60° or upwards, which command the outworks and the ground before the fortification. The space between two bastions is called the curtain. The use of the bastions is to bring every point at the foot of the rampart as much as possible under the command of the guns of the place, and that the fire may be directed on the approaches of the besiegers wherever the attack may be made. [See *figuro* in art. FORTIFICATION.]

Bastito. A name given to Schiller Spar, in consequence of its occurrence at Basti, in the Harz, where it is found in imperfectly defined greenish crystals, intermixed with serpentine.

Bat. [VESPERTILIO; DERMOPTERA; CHEIROPTERA.]

Bât Horses (Fr. *bât*, a pack-saddle). Are the horses which carry officers' baggage during a campaign. *Bât men* are the soldiers who look after these horses.

Batardeau (Fr.). In Fortification, is a strong gate to separate the wet from the dry part of a ditch; it is provided with a sluice gate.

Batata. A genus of *Convolvulaceæ*, including *B. edulis*, the Sweet Potato, a native of India, with fleshy sweet tubers, much cultivated for the sake of the latter in all the hotter parts of the world, and greatly esteemed as an article of food. Its name has now been popularly transferred to the potato (*Solanum tuberosum*), which has expelled it from cultivation in all temperate climates. *B. Jalapa* is a Mexican purgative species.

Bath (A.-Sax. *bað*). In Architecture, this word is reserved for a place for bathing. Among the ancients the public baths were of great extent, and consisted of a great number of apartments. The prodigious monuments of Roman magnificence seem to have been borrowed in some respects from the gymnasia of the Greeks, both the one and the other being instituted with a view to the exercise and health of the people.

BATH, ORDER OF THE

The word *therma*, which the Romans used in speaking of these edifices, signified a place for the reception of hot baths, but both hot and cold baths were generally comprised under the same building. In later times the Romans used the bath before they took their supper. The rich usually had hot and cold baths in their own houses, and it was not until the time of Augustus that the baths of ancient Rome assumed an air of grandeur and magnificence. Different authors reckon that there were as many as 800 baths in Rome. The most celebrated were those of Agrippa, Antoninus, Caracalla, Diocletian, Domitian, Nero, and Titus. Those of Diocletian were said to have been capable of containing 1,800 bathers. The vestiges of these stupendous buildings indicate the amazing magnificence, or the unbounded power of the rulers of the ancient world. Their pavements were mosaic, the ceilings vaulted and richly gilt and painted, the walls encrusted with the richest marbles; and many examples of ancient Grecian and Roman sculpture have been restored to the world from the ruins of these edifices. It was from the recesses of these buildings that Raphael took the hint for his decorations of the Vatican; and the first restorers of the arts in modern Italy drew largely from this source. The style of decoration called arabesque, or grotesque, which prevailed in Italy about this period, was mainly founded upon an imitation of the style followed in the baths of ancient Rome or its dependencies.

Of late years a great movement has taken place in favour of baths for the working people, and an Act of Parliament (called Sir H. Dukenfield's Act) has been passed for the purpose of facilitating their erection. The operation of this Act has been unsatisfactory on account of the limitations put upon the number of the superior baths, and the low price at which the cheap ones are paid; but the convenience of these baths is enough to justify the small public loss they have entailed. The reader who would desire to learn the details of this measure, and of the proceedings taken under it, is referred to the detached essay published by the Architectural Publications' Society, on *Baths and Washhouses*. In this essay will be found not only the history of the various steps taken under the Act, but also of the technical means adopted to carry out its various provisions.

BATH. In Chemistry, heated sand is often used as a medium for communicating heat, as glass and other vessels may be conveniently placed upon or immersed in it: sometimes water is used in the same way; hence *sand bath*, *water bath*, &c. The water bath is called by the old chemists *Balneum Mariæ*, and often abbreviated B. M.

Bath Metal. An alloy of copper and zinc, containing more zinc than in ordinary brass.

Bath, Order of the. A British order of knighthood. On the day of his coronation,

BATHOS

Henry IV. conferred the dignity of knighthood on forty-six esquires who had watched during the previous night, and bathed themselves, in pursuance of a very ancient custom derived from the usages of the ancient Franks. It was usual, from this period, to make similar creations of knights on royal coronations, espousals, and similar solemnities; but the custom was discontinued after the coronation of Charles II., until George I., in the eleventh year of his reign, instituted the present order of the Bath by letters patent. It consisted, exclusive of the sovereign, of a grand-master and thirty-six companions; and was a military order. In 1816, the order was greatly extended, and again in 1847, and is now composed of three classes—knights grand crosses, knights commanders, and knights companions, which classes again are each subdivided into three minor divisions—military, civil, and honorary. The knights companions take precedence of esquires. The badge worn by the grand crosses is a golden cross of eight points, enamelled white, with a lion of England between the four principal angles; on the centre a sceptre erect, or, having on the sides a rose, thistle, and shamrock, engrafted between three imperial crowns proper, encircled with a riband gules; thereon the motto of the order, 'Tria juncta in uno.' They also wear a silver star. The badge of the knights commanders is the same with that of the knights grand crosses, but smaller; their cross somewhat different. The companions have only the badge without a star.

Bathos (Gr. *depth*). In Rhetoric, a word signifying a ludicrous descent, from elevated to mean thoughts. [CLIMAX.] It has been chiefly rendered popular by Pope and Arbuthnot's *jeu d'esprit*, the '*Treatise on the Bathos*, by Martinus Scriblerus.'

Bathyllite. An inflammable mineral lately discovered by C. Groville Williams at Bathville in Scotland. It is a brown and exceedingly friable substance resembling Tripoli in appearance, and occasionally fills hollows in Torbanite.

Bathymetric Zones (Gr. *Bathys*, deep, and *metron*, measure). Divisions showing the distribution of animals and plants according to depth. Five of these zones have been defined so far as regards aquatic animals: 1. Littoral; 2. Circumlittoral; 3. Median; 4. Inframedian; 5. Abyssal. The life forms of these zones vary, of course, according to the nature of the sea bottom; and are modified by those primitive or creative laws which have produced in distant localities, under like physical conditions, species related by analogy.

Batidese. A small group of succulent Monochlamydeous plants closely allied to *Chenopodiaceae*, and containing but one genus, *Batis*, after which it is named. It yields barilla in great quantity.

Batolites. A genus of fossil shells, considered by Cuvier as *hippurites*.

Bâton (Fr.). The staff of a field-marshal.

BATTEN

Bâton. In Music, a term denoting a rest of four semibreves.

Bâtonnier (Fr., from Low Lat. *bastonarius*). In French, the elected president of an order or fraternity. The *bâtonnier* of the order of advocates is elected by the whole body. In ancient times he carried in their processions a staff (*bâton*) with the flag of Saint Nicholas, whence the name. He is president of the Council of Discipline.

Batrachians, **Batrachia** (Gr. *Bάτραχος*, a frog). An order of Reptilia, including the frogs and toads, and all reptiles which, like them, have naked skins and external branchiæ, in the early stage of existence; those *Batrachia* which retain the gills or gill-apertures throughout life are called 'perennibranchiate,' or 'amphibious.'

Batrachite (Gr. *Bάτραχος*). A variety of Chrysolite in which a great part of the magnesia is replaced by lime. It occurs massive, of a pale greenish colour like that of a frog, with a resinous lustre, at Ritzomberg, a mountain in the S. Tyrol.

Batrachomyomachia (Gr. *Βατραχομυμαχία*). The *Battle of the Frogs and Mice*, a mock heroic poem which has come down to us, and is attributed to Homer; but there is no probability that it was written by the author of the *Iliad* or *Odyssey*. (Mure, *Critical History of Greek Literature*, ii. 358.)

Batrachospermese (Gr. *Bάτραχος*, and *σπέρμα*, seed). A name proposed for such Algaeous genera as are articulated, and bear chain-like collections of spores. They mostly live in fresh water. *Batrachospermum* is the typical genus.

Batt. A highly Bituminous Shale, usually very compact, and splitting into the finest laminae, almost invariably black, and often interstratified in layers with coal. It is termed 'Black Bass' in Lancashire, and 'Black Slag' in Flintshire. (See Jukes, *On the Geology of the South Staffordshire Coal-fields*.)

Batta. A term applied to allowances made to troops in India. *Dry batta* is money given instead of rations, and *wet batta* is what is given in kind.

Battalion (Ital. *battaglione*; Fr. *bataillon*). A division of the infantry in an army, composed of a variable number of men. At present in the English service every battalion of infantry of the line at home has a normal strength of 800 rank and file, and those in India or the colonies have 60 to 200 additional. There is, however, no specific 'peace' or 'war establishment' for battalions. Their strength is regulated from time to time by the authority of the Secretary of State for War, according to the requirements of different stations and the exigencies of the service. In 1855 those serving in the Crimea consisted of no less than 2,000 rank and file, divided into 12 service companies, 4 reserve and 4 dépôt companies.

Batten. In Architecture, a name given by workmen to slips of wood from 2 to 7 inches broad, and 2½ inches thick, the length

BATTEN DOORS

considerable but undefined. The battens imported from Christiania, Gefle and St. Petersburg are usually from 6 to 7 inches wide, by $2\frac{1}{2}$ to $2\frac{3}{4}$ inches thick and about 16 or 20 feet long. They are usually sold by the St. Petersburg standard, that is to say, 120 battens, 12 feet long, $7'' \times 2\frac{1}{2}''$, are the recognised standard for 100 battens.

Batten Doors. A description of door filled in between a frame of deal or battens, with narrow battens laid vertically, so as to present a straight joint; the joints may terminate in a clamped flap, or be made bead butt, as the case may be.

Battened Down. When the hatchways in very bad weather are covered with strong gratings, and these with painted canvas nailed under long pieces of wood (battens), to keep the water from getting below the decks.

Battening. A kind of narrow framing used to protect walls from the effect of damp; or rather for the purpose of removing the lining from the walls for that purpose. Battening is also used for the purpose of lining the skirting of walls when there is a decided tendency to warp in the boarding used for that object, and it is usually made in narrow widths of $3\frac{1}{2}$ inches; the object of introducing these small widths being that the wood is less liable to shrink in them than when used in greater dimensions.

Batter. A term used by artificers to signify that a body does not stand upright, but leans from the spectator as he stands before it. When, on the contrary, it leans towards him, the inclination is described by saying that it overhangs.

Battering-ram. An ancient Military engine employed for beating down the walls of besieged fortresses. It consisted of a long heavy beam of timber, armed with iron at one extremity; and the effect was produced by pushing it violently with successive blows against the wall. The *ram* was worked in various ways. Sometimes it was simply supported by two files of soldiers, and the impetus given by a simultaneous thrust. More frequently it was slung from a cross beam, supported by two posts, by a rope or cable about its middle; in which case it had an oscillating motion, like a pendulum. A third sort was moved on rollers or wheels. Generally they were worked under a cover or shed (*vineæ* or *testudines*) to protect the assailants. These machines were often of immense size, and exceedingly ponderous, requiring 100 men to work them. Justus Lipsius describes a battering ram as 180 feet long, and two feet four inches in diameter, armed with an iron head weighing at least a ton and a half.

Battery (Fr. *batterie*, from *battre*, to beat). In Fortification, denotes the emplacement of two or more pieces of artillery destined to act offensively or defensively. Batteries may be open or covered by a parapet. They may be divided into *siege batteries* and *batteries for defence*. Siege batteries are either elevated,

BATTLE

when the guns are on the natural level of the ground; *half-sunken*, when part of the earth which forms the parapet is taken from behind it, so that the guns are in a shallow trench; or *full-sunken*, when all the earth is so taken, and the guns are in a deeper ditch. A *ricochet battery* is so constructed that its guns can fire along the interior face of an enemy's work with low charges and some elevation, in order to drop the shot over the parapet among the enemy's guns, so that the shot will rebound among the latter. A *breaching battery* is constructed to breach by its fire the face of an enemy's work.

Batteries for defence are either constructed to strengthen positions in the field, or are permanent in fortresses.

The word *Battery* is also used to denote a certain number of field guns, in our service six, united into one command, together with the officers, men, horses, and stores. Each field and horse brigade of artillery is thus divided into batteries. In the garrison brigades the word *battery* is synonymous with *company* in the infantry.

BATTERY. In Law, the unlawful beating of another: 'assault and battery' means therefore an assault comprising such beating.

Battery, Electrical. A series of Leyden jars so arranged that they may all be discharged at once. [ELECTRICITY.]

Battery, Galvanic. [VOLTAIC ELECTRICITY.]

Battle (Ital. *battaglia*, Fr. *bataille*). In the art Military, an engagement between two hostile armies for the accomplishment of some great object. A battle is the most important event in war: it is the consummation to which all the previous combinations of a general necessarily tend; it is that grand act of war which may decide the fate of kingdoms and of nations as well as that of armies and campaigns. In the early ages of the world a battle was merely a fierce and bloody struggle, the issue of which depended more on the physical strength of the combatants than any scientific combinations which the general could adopt; but as the arts and sciences progressed, the military system was improved; and the battle of Marathon (the first well-authenticated battle in profane history) demonstrated how far superiority in physical strength may be compensated by generalship and discipline. A further illustration of this fact is afforded in the subsequent battles of Plataea, Mantinea, and Leuctra, among the Greeks; and the banks of the Ticinus, the lake of Thrasymenus, and above all the plains of Cannæ, are memorable for engagements which for ingenuity of design and dexterity of execution have excited the admiration of soldiers in every age. But to give even a faint sketch of the various exploits which were achieved by the Grecian so-called *oblique system*, the Macedonian phalanx, and the Roman legion, and of the different military principles involved in their construction, would be to furnish a

history of these different nations; and we must content ourselves with referring the reader to the article 'Bataille,' in the *Encyclopédie des Gens du Monde*, where some concise though scientific details upon this subject will be found. Though the weapons employed in battle in modern times are widely different from those in use among the ancients, and though many circumstances have combined to give an entirely different aspect to the military systems of the two periods, still it is surprising how strong a resemblance to each other is displayed in their groundwork; and it will be found on examination that the grand principles which even in the present century were adopted by Napoleon and the duke of Wellington were practised, though imperfectly, by Epaminondas on the field of Leuctra. Indeed, it is a circumstance worthy of note, that the changes which in every age have taken place both in the manners and the weapons of nations have had no perceptible influence on the grand leading principles of military tactics. 'Les tétarchies,' says a French author, 'et les manipules sont représentées chez les modernes par les pagnies: les régiments ou syntagmes et les cohortes romaines, par les bataillons; enfin, les phalanges et les légions, par les régiments, les brigades ou les divisions.' There are three combinations of which a battle is susceptible: 1. *Defensive*, which consists in taking up a position, and defending it against the enemy. 2. *Offensive*, in which the object is to harass the enemy at all points and on all occasions. The third is a medium between these two, and presupposes on the part of the general sufficient skill to know when to make an attack, and when to act on the defensive. It is impossible to state precisely the principles which should guide a general in the adoption of one or other of these three systems, from the difficulty of providing against unexpected events which often occur to perplex or overturn the most matured and ingenious plans.

Battles are reducible to three orders, subject to slight modifications:—

1st. The simple parallel order, where both armies face each other, and the best soldiers win the day, independently of science.

2nd. Parallel lines reinforced on one extremity. This is most generally applicable, and by it most modern battles have been won.

3rd. The oblique order of battle, which is the best, and if skilfully applied is instantaneous and decisive in its effects.

For a full and elaborate view of the principles involved in a battle, the reader may consult with advantage Jomini's *Traité des Grandes Opérations Militaires* (Paris, 1824); a system which is founded on the united principle of a concentration of the forces and the commencement of hostilities.

Battle-axe. A Military weapon, which is purely offensive. It was not employed by the Greeks and Romans, though it was found among contemporary nations. At the siege of the Roman capitol by the Gauls under Brennus, the

most distinguished warriors were armed with battle-axes; and Ammianus Marcellinus states, that this instrument formed part of the offensive armour of the Gauls from time immemorial. In England, Scotland, and Ireland, the battle-axe was much employed: the Lochaber axe, in particular, was long a formidable implement of destruction in the hands of the Scottish Highlander, and obtained an almost universal reputation.

Battlement (Fr. *bâtiment, a building*). In Architecture, this word is used to denote a wall or parapet on the top of a building, with embrasures, or open places, to look through, or to discharge missiles for the annoyance of an enemy.

Battology (Gr. *βαττολογία*). In Grammar, superfluous repetition.

Battue (Fr.). In Sporting, a term signifying a practice of huntsmen, which consists in encompassing a certain portion of forest, and in endeavouring by beating the bushes, as well as by loud cries, to bring out the animals of chase which may chance to be within it.

Battuta (Ital. *a beating*). In Mus. the motion of beating with the hand or foot in directing the time.

Baudisserite. A Mineralogical synonym for Magnesite; after the locality Baudissiero in Piedmont.

Baueraceæ (*Bauera*, so named after Mr. Bauer, their discoverer). A small natural order of New Holland shrubs with pretty purple flowers, related to *Hydrangææ* and *Saxifragaceæ*. There is but one genus, *Bauera*.

Baulite. A variety of Pitchstone ejected from the volcanoes of Iceland and Faroe. It is named after the mountain of Baula in Iceland.

Baulk (Swed. *balk*, Dan. *biælke*). A piece of whole fir, being the trunk of a tree of the species usually squared for building purposes. In the metropolis the term is only applied to small lengths from 18 to 25 feet, mostly under 10 inches square, tapering considerably, and with the angles so left that the baulk is not an exact square.

Bauxite or Beauxite. A ferruginous hydrate of alumina. Large deposits of Bauxite occur in the department of the Bouches-du-Rhône (commune of Baux, near Arles), and in the departments of the Gard and Var in the South of France.

Bavalite. A silico-aluminate of oolitic iron found at Bavalon in France.

Bavins. Are small faggots of furze or brushwood, dipped in some inflammable composition. They are employed among the combustibles stored in a fireship.

Baxterians. In Ecclesiastical History, a name applied to those English theologians who adopted the sentiments of Richard Baxter on the subject of grace and free will, forming a sort of middle way between Calvinism and Arminianism. They never formed, strictly speaking, a sect, and the name is now disused: nevertheless, similarly modified religious opinions are common among Nonconformists at this day.

BAY

Bay. A word used to indicate any principal compartment of work, when it lies between fixed divisions: thus, a bay of flooring is the portion of the flooring between two or more divisions; a bay of roofing is that portion between two purlins. It is also used to express a portion of a barn, or any other building, when it is divided into lengths by cross partitions. A *bay window* is generally understood to mean a window so planned as to form a recess out of the room to which it belongs.

BAY (A.-Sax. *bige, byge*). A name applied to portions of the sea partly surrounded by land, but having a wide open communication with the ocean. Hudson's Bay is an extensive and remarkable sea on the eastern side of North America, more nearly enclosed than quite justifies the title of Bay. Its area nearly equals that of the Mediterranean. The Bay of Biscay is a better example. It is open to the Atlantic, but partly enclosed by the West of France and the North of Spain. Another instance is the Bay of Bengal in the Indian Ocean.

Baffin's Bay is a very extensive gulf, reaching far into the Arctic circle, and its shores are generally high and backed by mountains covered with perpetual snow. It is the source of a large number of the icebergs that float down the east coast of America. [INLAND SEAS AND GULFS.]

Bay Salt. A large-grained salt, obtained by the spontaneous evaporation of sea-water, exposed in large shallow pits (bays) to the full influence of sun and air. The term *bay salt* is often applied indiscriminately to any kind of coarse-grained salt. [SALT.]

Bayonet (Fr. *baïonnette*, said to be so called as having been first made or used at Bayonne). A short triangular sword or dagger fixed upon the muzzle of a musket, which is thus transformed into a thrusting weapon. The original invention and subsequent improvement of the bayonet are due to the French, who first used it in the Netherlands in 1647, and the advantages which this weapon gained to that nation soon attracted notice to its merits. In the last half of the seventeenth century, it was everywhere substituted for the pike, and in some instances it has decided the issue of an engagement without a single shot being fired. About the year 1690, the bayonet was first fixed to the side of the barrel, instead of being placed in the bore. Cavalry are often counted by *horses*, and infantry by *bayonets*.

Bazaar (from an Arabic word, signifying traffic or merchandise). A large square or street where merchants in Eastern countries have their shops or warehouses.

Bellium (Gr. *βέλλιον*). An African gum resin of a bitter nauseous taste and a dark-brown colour. It is sometimes mixed with myrrh.

Bellostomes, Bellostoma (Gr. *βέλλα, a leech*, and *στόμα, a mouth adapted for suction*). A genus of Cyclostomous fishes.

BEAM

Beach (a word of uncertain origin). A sea beach is that expanse of gravel, rolled shingle, shells, coral, and sand, or whatever corresponds to such things, exposed on the sea coast to tidal action. Not unfrequently on the south-west coast of England, the coast of Wales, the shores of the Baltic and elsewhere, such beaches are found at various levels above the regular action of the tide, and far above all such occasional marine influences as must have produced them. They are then called **RAISED BEACHES** [which see].

Beacon (A.-Sax. *beacen*, allied to the English words *beck, beckon*). A fire lighted by way of signal on a height, or the place where such signals are usually made. Along the southern coast of England, many of the highest hills are provincially termed 'beacon,' from this circumstance. There is a celebrated poetical description of the transmission of news by fire signals, from height to height, in the *Agamemnon* of Æschylus. The English beacons were erected under the superintendence generally of the lord high admiral; they were usually pitch-boxes, or fire-pots, and their maintenance and watching was defrayed by a rate levied on the country. The term Beacon is also applied to marks or signs raised on the shore, and on head-lands and over shoals, for guiding vessels at sea by night as well as by day.

Bead (Sax. *beaþe*). In Architecture, a moulding whose vertical section is semicircular.

Beak (Fr. *bec*, Gael. *beic*). In Architecture, a small fillet on the underside of the crown moulding of an entablature, followed by a hollow for the purpose of throwing off the water from it under the base of the corona.

BEAK. In Botany, a hard sharp termination of any part of the fructification. It is Latinized by *rostrum*.

Beak-head. In large vessels with figure-heads, is the small platform between the figure-head and the bulwarks of the forecastle. It is secluded from the view of the deck, and contains the latrines of the crew.

Beam (A.-Sax. *a tree*; Ger. *baum*; Dutch, *boom*). In Architecture, a horizontal piece of stone, or of wood. The term is also applied to cast or wrought iron, which is introduced in building operations to carry a vertical load over an opening, where it resists an effort of cross strain. It is called a *tie beam*, when the piece of timber is intended to resist the outward thrust of the weight, as in the framing of a roof. The beam which is introduced in the external walls of a building to carry the weight of an upper structure is called the *bressummer*.

BEAM. In Nautical language, the width of a vessel. Thus a wide vessel is said to have *more beam* than a narrow one; the beams being the strong pieces of timber stretching across the ship from side to side, for the purpose of supporting the decks and retaining the sides at their proper distance. When a ship is lying entirely on her side, she is said to be *on her beam ends*. When this is the case in a hurricane or heavy gale, there is often no other

BEAM FILLING

resource to *right* the ship than cutting the masts away.

A-beam. In the direction perpendicular to the ship's length, a-midships. Thus an object seen from the middle of a vessel, 90 degrees or 8 points from the head or stern, is said to be a-beam.

Beam Filling. The filling in of masonry, or of brickwork, between beams, or joists; its height being equal to the depths of the timbers filled in.

Beam-tree. A deciduous British tree of small growth, inhabiting the mountainous parts of the country, and resembling a small apple tree, with berries like those of the mountain ash. Its leaves are strongly veined in a plaited manner, and white underneath; the wood is hard, compact, and tough, and is used for axletrees, naves of wheels, and cogs of machinery. The *Pyrus Aria* of botanists.

Bean (A.-Sax.). The Bean, *Faba* of botanists, is a leguminous crop of considerable importance on stiff soils, occupying often a sixth of the arable land; and thus furnishing a considerable portion of the income of the farm. From 32 to 40 bushels are grown per acre. Seven or eight varieties are known to English agriculturists. It is used chiefly as horse corn; though it is also given as food to cattle, sheep, and pigs while fattening. The ordinary weight per bushel is from 60 to 64 lbs.

The Winter Bean, hardier than the other sorts, is sown in October or November and harvested in July; it is adapted to a lighter soil than the other kinds, which are sown in February and March, and are ripe in September and October.

Bean Ore or Bohnerz. A term applied to Brown Iron-ore when it occurs in spherical or ellipsoidal concretions, with a concentric lamellar structure.

Bear. [UNUS.]

Bear's Foot. [HELENORE.]

Bearberry. The *Arctostaphylos uva ursi*. The leaves of this plant, under the name *uva ursi*, are used as an astringent and tonic in medicine.

Beard (A.-Sax.). The gills or breathing organs of the oyster and other bivalves are vulgarly so called.

BEARD. [BARBA.] When applied to corn, it is used in the sense of *AWN* [which see].

Bearer. In Architecture, any upright piece used to support another.

Bearing. In Geography and Navigation, the direction, or angular distance from the meridian, in which an object is seen. The position of an observer, or of a ship at sea, may be ascertained by determining the bearing of any fixed point, whose position and distance are known, or the bearings of two known points. In the latter case the angles and a side of a triangle being given, the other sides can be easily calculated by trigonometry.

Beasts (Lat. *bestia*, Gael. *biast*). As charges in Heraldry, are said to be rampant, when represented rearing; sejant, when seated; stantant,

BEAUTY

when standing; couchant, when lying; salient, when springing; passant, when walking (but the words *lodged*, *springing*, and *tripping*, are used of a beast of chase in these positions); gardant, when full-faced; regardant, looking back; dormant, sleeping; nascent, rising out of the middle of an ordinary; issuant, rising from its top or bottom. Two animals represented side by side, but moving in opposite directions, are said to be counter-passant, &c.

Beat (A.-Sax. *beatan*, to *beat*). In Music, reversed shake without a turn. The word has also the same meaning as *BATTUTA* [which see].

BEAT. To *beat*, *beat up*, or *beat to windward*, in Navigation, is to make progress against the wind by a zigzag course, and is the same working to windward.

Beatification (Loy Lat. *beatificatio*). In Roman Catholic Theology, the process whereby the church confers the title of 'blessed' on one deceased; inferior, and commonly preliminary, to CANONISATION [which see].

Beau Ideal (Fr.). In Painting, that beauty which is freed from the deformity and peculiarity found in nature in all individuals of a species. All the objects which nature exhibits to us have their blemishes and defects, though every eye is not capable of perceiving them; and it is only by long habit of observing what any objects of the same kind have in common that it acquires the faculty of discerning what each wants in particular. By such means the artist gains an idea of perfect nature, or what is called the *Beau Ideal*. [IDEAL.]

Beaumontite. A mineral resembling Heulandite, found in minute crystals on syenite-schist with Haydenite, at Jones's Falls, near Baltimore. Named after Professor Élie de Beaumont.

Beauty (Fr. *beauté*). In the Fine Arts, that result of all the various perfections of an object, which pleases the senses, and more particularly the eye. With the painter and sculptor, nature, refined by selecting from the most perfect of the species, is the index and guide; but with the architect the creative power of nature herself is the model of imitation. Some of the sources of beauty have been seriously considered by Burke as consisting in smallness, smoothness, delicacy, and the like; but such speculations are absurd. The primary source of all beauty in the three arts is *harmony of form*; on that alone must the artist depend if he would produce a work capable of pleasing. In painting, colour decks a work with many charms; but they are all subordinate to that great effect which beautiful form, unaided by all accessories, is capable of producing on the mind. As form is constituted by lines, it seems probable that an enquiry into their nature might lead the artist to the formation of beautiful forms; and it was doubtless this feeling which led Hogarth, in his *Analysis of Beauty*, to place so much to the account of the serpentine line. But in the arts generally the principles are infinitely more extended; for

BEAVER

lines which, from their propriety in one art, are strikingly beautiful, become absolutely absurd as sources of beauty in others. Hence we arrive at one general conclusion, that in all of them perfect fitness and proportion so as to make the object in harmony with nature, are the surest guide to beauty of line, and thence naturally to beauty of form. If this be so, no general laws save those dependent on fitness and proportion, can be laid down; and perhaps it would not be a difficult task to trace to them all those associations which seem to be connected with the subject in its effect on the mind.

Beaver. [CASTOR.]

Bebearine. A bitter basic principle contained in the bebearu plant, or *Greenheart*, of British Guiana.

Bechicus (Gr. *βήχης*, from *βήξ*, a cough). A medicine for the relief of coughs.

Beckets. On Shipboard, are hooks, or other apparatus, used for keeping ropes, tackle, oars, or spars in their appropriate places.

Bed (A.-Sax.). In Architecture, the horizontal surface on which the stones, or bricks, of walls lie in courses.

Bed. In Geology, this term is said to imply the natural layers of a stone, and it is therefore different from the planes of cleavage, which may be, and often are, very distinct from those of the stratification of the material. The general character of the bedding of a stone is that it should be more easily detached in that direction than in any other, and the fossils which may be contained in it are more frequently deposited conformably to it. Some kinds of stone are, however, very deficient in the planes of their bedding, and they yield a homogeneous, amorphous mass devoid of any divisional planes. In using materials of this description care is required to place them in the natural way of the bed, especially in cases where that characteristic is very decidedly marked. Where the bedding is not distinct, it is a matter of indifference which side may be presented to the action of the atmosphere. With some of the freshwater limestones of the Paris basin and of the Jurassic series, there are instances of stones being used with impunity in 'false bedding,' as the phrase is; but these are exceptional cases, and are manifestly liable to mislead.

Bed of Justice (Fr. *lit de justice*). In French History, a solemn proceeding to which the monarchs of France had recourse on particular occasions. As is well known, the parliament of that country had a right to resist any commands or decrees issued by the sovereign. If, however, the king insisted on the fulfilment of his wishes, he proceeded to hold a 'lit de justice' i.e. he went in person to parliament, attended by the chief officers of the court, and there, mounting the throne (called in the old French language 'lit'), caused those commands or decrees which the parliament had rejected to be registered in his presence. This had the effect of intimidating the parliament into compliance; and the means which it usually adopted

BEEKITE

to intimate its dissatisfaction was to enter a protest against the whole proceeding.

Bed Moulding. In Architecture, those mouldings which are, in all the orders, between the corona and the frieze, or other large soffits.

Beds. In Geology, seams of strata, thick or thin.

Bedchamber, Lords of the (or, as they were called before the accession of the House of Hanover, *Gentlemen of the Bedchamber*). Are officers of the royal household, under the groom of the stole; their number has usually been twelve, and they wait in turn, a week each. This office is performed by *ladies* during the reign of a queen. [HOUSEHOLD.]

Bedeguar (*the sweet-briar sponge*). A species of gall found upon various species of *Rosa*, but most frequently on the briar; it is produced by the puncture of several insects, and looks like a ball of moss, at first green, but afterwards becoming red or purple. It was formerly used in medicine as a diuretic and vermifuge. Pliny says that the ashes of this fungus, mixed with honey, or with bear's grease, were used as a liniment for baldness.

Bee. [APIS.]

Bee-eater. [MEROPIDANS.]

Bees. On Shipboard, are pieces of elm plank bolted to the bowsprit at its upper end.

Beech (A.-Sax. *bece*). One of the forest trees of the north of Europe, the *Fagus sylvatica* of botanists, belonging to the natural order *Corylaceæ*. Its fruit, or mast, consists of triangular nuts enclosed in a spiny husk or cupule, of the same nature as the cup of the acorn, only of a different shape, and covering the nuts all over. Its wood, which is hard and rather handsome, is brittle and perishable, and particularly liable to become worm-eaten. It is chiefly used by turners and millwrights. The Purple and Copper Beeches seen in plantations are seedling varieties of *Fagus sylvatica*.

Bee-eater (by corruption from the French *beaufetier*, an officer appointed to watch the beaufet, buffet, or side-board). A popular appellation for the yeomen of the king's guard,

derived from the circumstance that they originally were ranged at table on solemn festivals.

Bee-kite. An incrustation of Chalcedony, deposited in concentric circles around minute tubercles on fossils, sponges, corals or shells—generally spiral univalves—and occasionally, but rarely, upon fragments of limestone. It occurs in masses of irregular shape: most commonly they are more or less rounded, and vary in diameter from half an inch to a foot, seldom exceeding from three to six inches. Bee-kites have been found at Valdeas near Madrid; in Australia; on the banks of the Nerbuddah in India; and sparingly near Sidcot in Somersetshire and in the North of Scotland. They are, also, found in the New Red Conglomerate of Torbay in Devonshire, especially at Livermead Head, and about Paignton Harbour.

Named after Dr. Beeke, dean of Bristol, by whom they were first described.

BEELZEBUB

Beelzebub (Heb.). A god of the Philistines, who had a famous temple at Ekron. His name signifies literally the destroyer of flies; and if we consider the torment which those insects occasion in the East, it will not seem surprising that the Philistines conferred on him this appellation. Thus, also, Apollo is thought by many to have received his name of Smintheus, as being the destroyer of mice. In the later demonology of the Jews, Beelzebub was represented as the chief of the devils. See the description of Milton, *Paradise Lost*, ii.

Beer (A.-Sax. *bær*). The wine of grain. It is usually made by fermenting an infusion of barley malt and of hops, and bears different names according to its strength and colour. It is nutritious from the sugar and mucilage which it contains, exhilarating from the spirit, and strengthening and narcotic from the hops. Professor Brande obtained the following quantities of alcohol from 100 parts of different beers:—Burton ale, between 8 and 9; Edinburgh ale, 6 to 7; Dorchester ale, 5 to 6; the average of strong ales being between 6 and 7; brown stout, 6 to 7; London porter about 4 (average); and London brewers' small beer between 1 and 2. [FERMENTATION.]

Beetings. [BEESTING.]

Beet (Fr. *bette*). The succulent root of *Beta vulgaris*, a Chenopodiaceous plant of biennial duration. It is used in the winter as a salad, for which purpose the red and yellow Beets of Castelnau-dari are the best; for the food of cattle, under the name of Mangold Wurzel; and for the extraction of sugar. For the latter object a white-rooted variety with a purple crown is the most esteemed. Sea Beet (*Beta maritima*) is a well-known substitute for spinach. Chard or Sicilian Beet is the *Beta Cichla*. The Field Beet, or Mangold Wurzel, is now a crop of great agricultural value on account of its large produce (25 to 30 tons per acre) of nutritive succulent roots, which are good and fattening food for cattle, sheep, and pigs. It is sown in April or May (in rows 30 inches wide) at the rate of 6 or 7 lbs. of seed per acre. It is singled out at intervals of 12 to 18 inches in the row, and single roots weigh from 5 to 15 lbs. It is adapted to the stiffer class of soils, and it has introduced on them all the advantages which turnip culture has conferred on the lighter soils. The roots are drawn and pitted in October, and given to cattle and sheep during the spring months.

Beetle (A.-Sax. *bytel*). A large wooden hammer or mallet, with one or more handles, with which piles, stakes, wedges, &c. are driven.

BEETLE (A.-Sax. *bitola*). A name commonly given to the insects of the Coleopterous order, especially to such as are of a dark or obscure colour; it is also applied, but improperly, to the common pest of our kitchens, the blatta, or cockroach, which is an insect of the Orthopterous order.

Beetle or Bettle Stones. Names sometimes given in South Wales to septarian nodules of Clay Ironstone from the Coal Measures.

BEHEMOTH

Beghards (derivation uncertain). A name in common use in the middle ages, frequently applied to the Franciscan and other mendicant orders, denoting, as some say, the practice by which they gained their subsistence. The Beghards formed a sort of intermediate class between the monks and laity, and were known under various denominations; as the tertiaries or half monks of the mendicant orders, the fraternity of the weavers, the brethren of St. Alexius, &c. But the term has also been affixed to a set of persons who, in the thirteenth century, became notorious for the frequency and ardour of their prayers.

Begoniaceæ (*Begonia*, the principal genus). A natural order of diclinous monoclinandrous Exogens, with showy pink, white, or yellow flowers, and handsome succulent leaves, which are frequently richly coloured or gaily variegated, and have one side considerably larger than the other. The leaves have large stipules, and a subacid flavour. Much difference of opinion exists among botanists as to their affinity. They generally inhabit the dampest parts of the tropics. Begonias are favourites with cultivators, both for their beauty and the facility with which they are maintained in health.

Beguins (Fr. *beguin*, Low Lat. *beghina*). A class of women throughout Germany and the Netherlands, who as early as the eleventh century, without taking vows or following the rules of any order, united themselves for devotional and charitable purposes, and were distinguished from the great body of the laity of those times by their industrious, pious, and secluded habits, and by their attention to the education of the young. Their conduct was imitated by men, who formed a union for similar purposes, and were called Beghards [which see]. The Beguins continued to exist in Germany up to the Reformation, under the name of 'seelen weiber' (spiritual women), from the interest they took in the spiritual concerns of their sex. There are now in some Roman Catholic countries societies or beguinages of females, who live together after the manner of nuns without taking vows, but by their mode of life and profession maintaining the same intermediate state between the laity and the clergy which was first remarkable in the Beghards and Beguines of the eleventh century. The most celebrated are at Ghent and Malines.

Behemoth (Heb.). The name of an animal, of which some of the characters and attributes are described in poetical language in the 40th chapter of the Book of Job. Much pains have been taken to identify the creature there referred to; but it must be remembered that the discovery and general adoption of a mode of description, which combines exactness with brevity and is applicable only to the object described, are the results of a recent and highly advanced state of zoological science. Even the prosaic, and, so far as they went, scientific descriptions of animals in the writings of Aristotle, are rarely so copious and

BEL ESPRIT

precise as to enable a modern naturalist to identify the existing species there referred to. But the aim of Job in the verses in which he sings of *Thau*, *Leviathan*, *Behemoth*, was to show forth the power and wisdom of the Deity and lower the pride of man, by appealing to the wonderful powers assigned to some of the most remarkable and formidable objects of animated nature with which he was acquainted; and it can hardly therefore be expected that curiosity, eager to hunt out the precise species spoken of, should be gratified. Enough of doubt has always been left to shake the most sagacious conjectures; and some recent inquirers into Biblical zoology, perceiving that the properties of *Behemoth* were not manifested to the letter in any known existing species, have endeavoured to make the scriptural allusions square with the characters of some one of the gigantic extinct animals: the *Iguanodon*, for example, a supposed herbivorous reptile, with a horn on the nose, and a long and flexible tail, has been selected as the species described by Job, ch. xl. The allusion, in verse 17, to a part of the generative organs, visible externally only in the class of *mammalia*, renders it very improbable that *Behemoth* could be one of the *Reptilia*. The exclamation, also, 'Behold he drinketh up a river and hasteth not! He trusteth that he can draw up Jordan into his mouth,' could not with any appearance of truth be applied to a species of a class of animals of which the organisation requires them to drink so little and so seldom. If a *mammiferous* quadruped, then *Behemoth* was a herbivorous and ungulate species: 'He eateth grass as an ox' (verse 15); but, unlike the males of the larger ruminants, he had not a divided scrotum, for 'the sinews of his stores were wrapt together' (verse 17). Thus from the few zoological characters which are brought under our consideration, we come to the conclusion that some huge pachyderm, whose haunt was in the fens, whose place of retreat was encompassed by the willows of the brook, and overshadowed by trees, was 'the chief of the ways of God,' in the language and mind of the sacred poet.

As there exist differences of opinion among the best Hebrew scholars as to the exact signification of the first part of verse 17, which some have rendered, 'He sitteth up,' and of the second part of verse 19, where allusion is made to some weapon, these become obviously unsafe elements, in the consideration of the zoological problem.

Bel Esprit (Fr.). A term once commonly used in England, applied to persons of sprightliness and vivacity whether in writing or in conversation.

Belay, Belaying. On Shipboard, is the act of fastening any rope of the running rigging by twisting it round a cleat, kevel, or belaying pin.

Belemnites (Gr. *βέλεμον*, a dart). A genus of fossil Dibranchiate Cephalopods, the shells of which are chambered and perforated by a siphon, but internal. They are long,

BELLADONNA

straight, and conical; and commonly called 'thunder stones.' These fossil remains are often found in chalk.

Belfry (Fr. *beffroi*). In Architecture, this word is applied exclusively to the towers in which bells are hung. [CAMPANILE.]

Belial. A Hebrew word, signifying wicked, worthless, and unprofitable. Thus the sons of Eli are called sons of Belial, for their idolatrous and criminal conduct (1 Sam. ii. 12); and St. Paul (2 Cor. vi. 15), in order to indicate in the strongest terms the high degree of virtue after which the Christian should strive, places Christ in direct opposition to Belial. Milton has assigned to Belial a prominent place among the adherents of Satan in his *Paradise Lost*.

Bell. A hollow vessel, or body, made so as to emit sound on being struck by some instrument. Bells are probably of very ancient origin. They are mentioned as worn on the high priest's robes (Exod. xxviii. 3). They were used by the Greeks and Romans in private houses, and in camps and garrisons. Bells are said to have been brought into use for churches by Paulinus, bishop of Nola, in Campania (whence the name Campana), about the year 400: they are first mentioned in England by Bede, towards the end of the seventh century. A bell consists of the ear, or canon, by which it is fixed to the bell cage, and of the barrel; the proportions of the barrel are—diameter at the mouth 10, diameter at the shoulder 5, height from the mouth to the shoulder 8, one-fiftieth part of the diameter being about the thickness of the *sound bow*, or that part of the bell where it is struck by the clapper, which is usually made of wrought iron.

Bell Metal. A hard, brittle, dense, and sonorous alloy of copper with tin, zinc, or some other metal. The proportion in English bells is usually about 75 per cent. of copper to 25 of tin; but they vary from 50 of copper to 33 of zinc and 17 of tin; to 80 of copper, 10 of tin, 6 of zinc, and 4 of lead; and occasionally to 72 of copper, 26.5 of tin, and 1.5 of iron. The proportion of 80 of copper to 20 of tin, or 78 of copper to 22 of tin, is the bell metal of commerce.

Bell Trap. A contrivance for the purpose of securing an air-tight communication between a sink and a cistern, or a cup for determining the flow of the water to the outfall.

Bell-metal Ore. A name which has been given to Tin Pyrites (native sulphide of tin) in consequence of its resemblance in appearance to the kind of bronze called bell metal. It is found in several Cornish mines, especially in those of Carn Brea.

Bells. On Shipboard, bells express the time as recorded by the officer of the watch. When the half-hour sand-glass runs out, the bell of the ship is struck: the number of blows increasing by one each half-hour, until the watch is expired. The bells thus reach eight in each of the long watches, and four in each dog watch.

Belladonna (*Atropa Belladonna*). The Deadly Nightshade, an acro-narcotic poison.

BELLEROPHON

The name *bella donna* (Ital. *handsome lady*) is said to have been given from its having been used to improve the complexion. It contains the alkaloid *atropia*.

Bellerophon (Gr. Βελλεροφόντης). In the mythology of Argos, a name given to Hippodamias, the son of Glaucus, and grandson of Sisyphus (Paus. 2. 4), when he fled from Corinth for the murder of Bellerus, and sought refuge at the court of Proetus. There Antea, the wife of Proetus, conceived a violent attachment for him, which he requited as Joseph did the advances of Potiphar's wife. Nor does the analogy between the cases end here; for Antea forthwith accused him to her husband of attempt on her virtue. Proetus, however, unwilling to violate the laws of hospitality, sent him to Iobates, king of Lycia, his wife's father, with a letter, consisting of pictured signs, desiring him to put Bellerophon to death, and mentioning the cause. (Hence, a letter unfavourable to the bearer was called 'Litera Bellerophontis'.) With this view, Iobates sent him on various perilous expeditions: first, against the Chimæra, which Bellerophon succeeded in destroying by the aid of a winged horse called Pegasus [PEGASUS], which he had caught while drinking at the fountain Pirene in Corinth. In his next expeditions against the Solymi and the Amazons, he was equally successful (Horn. *Iliad*, vi. 155), and after it he married the daughter of the Lycian king. According to a version not noticed by Homer, Bellerophon, elated by his success, tried to fly to heaven on Pegasus; but Jupiter, enraged at his presumption, frustrated his attempts by sending a gad-fly, which stung the horse so violently that he became restive and threw his rider. Though maimed and shattered by the fall, Bellerophon was not killed; but he never perfectly recovered. In the *Iliad*, vi. 201, he is described as wandering alone in his later years through the Aëlian plain, avoiding the path of men. Bellerophon was celebrated for his skill in horsemanship (Hor. *Ode*, iii. 12. 7), and is said to have first taught the art of riding. (Plin. *iv*. 56.)

BELLEROPHON. A fossil shell, the animal of which was probably allied to that of *argonauta*. The genus belongs to the carboniferous and older strata.

Belles-lettres (Fr.). Polite Literature. Almost all authors concur in censuring the vague and indefinite character of this term, as at one time every branch of knowledge has been included under this denomination, at another excluded from it. In the division of the departments at the Lyceum of Arts, established at Paris in 1792, the belles-lettres comprehended general grammar, languages, rhetoric, geography, history, antiquities, and numismatics; whilst philosophy and the various branches of the mathematics were called, in contradistinction, sciences. Rollin and Rosenstein, who professedly treat of the belles-lettres, comprehend under the term all those branches of knowledge which chiefly occupy

BELLES-LETTRES

the memory and the understanding, and do not form part either of the superior sciences or of the mechanical professions. In an enquiry of this kind, reference must necessarily be made to Hume, who, both from the nature of his pursuits and the bent of his mind, was well qualified to give an opinion, and who asserts, that the belles-lettres improve our sensibility for all the tender and agreeable passions, at the same time that they render the mind incapable of the rougher and more boisterous emotions.

But though it would appear difficult to reduce this term within the limits of a precise and accurate definition, there can be little doubt that there are few terms which present so distinct a meaning to each individual mind. The influence of the belles-lettres has been felt and acknowledged in all ages. The tribute paid to them by Cicero in his defence of Archias is familiar to all. In the beautiful letter to Mæcenæ, who was afflicted with some mental distemper, Horace first advises his friend to have recourse to the study of polite literature, and then concludes in these general terms:—

Invidius, iracundus, iners, vinosus, amator,
Nemo adeo ferus est, ut non mite-cere possit,
Si modo cultura patientem commoedet aurem.
Ep. 1. 1. 40.

It would greatly exceed our limits to give even a cursory view of the belles-lettres in the decline and fall of the Roman empire; but we refer the reader to Schlegel's *History of Literature*, and to Hallam's *Introduction*, &c., for full information on this head. It may, however, be remarked, that during the long period of the middle ages (which has been often, though erroneously, considered as a blank in the history of the human mind), learning was almost wholly confined to the church; and though there was little original genius displayed in the province of imagination, yet here was preserved the germ of the future polite literature of Europe. As early as the fourteenth century, the spirit that had long been slumbering, was reanimated by the genius of Petrarch, and burst forth like a meteor in the Italian republics. Its genial influence was soon felt on this side the Alps; and in the year 1400, as Mr. Hallam observes, Spain, France, England, and Germany were in possession of a national literature. The traces of this spirit, however, were soon obliterated, and its effects gradually swallowed up in those that everywhere ensued, and in the all-absorbing taste for metaphysical and theological disquisitions that subsequently prevailed.

It is to the Reformation that the origin of polite literature in modern times may properly be ascribed. Among the first fruits of its effects upon the interests of the belles-lettres in England, it may suffice to mention the names of Spenser, Shakspeare, and Milton, who have embodied in their writings all the riches of the English language, and whose works are of themselves sufficient to furnish any nation with a polite literature of which it might justly be proud.

BELLIS

The close of the last and the dawn of the present century may be regarded as an era in the history of polite literature throughout Europe. [LITERATURE.]

Bellis (Lat.). The Daisy, *Bellis perennis*, is a well-known humble wild flower of the Composite order, and an especial favourite of the poets. There are several garden varieties of this modest flower. One of them has profuse flower-heads.

Bellona (Lat.). In Mythology, a deity worshipped by the Romans as the goddess of war. She possessed a temple, built and dedicated to her by Appian Claudius, which stood in the Circus Flaminius, near the Porta Carmentalis. It was here that the senate granted audiences to foreign ambassadors, and received generals on their return from abroad. In front of this temple also stood the pillar against which the javelin was hurled, the usual preliminary among the Romans to a declaration of war. The priests of this goddess, who were termed *Bellonarii*, consecrated themselves by incisions in their bodies, and sacrificed to her honour the blood which flowed from their wounds. [ÆTIO.]

Bellows (Ger. *bälgen*). A machine contrived to propel air through a tube or orifice, with more or less compression. It is used for blowing fires, supplying the pipes of organs, and other purposes, and is constructed of several forms, but the principle is the same in all of them. The dimensions of the space within which air is confined are contracted; the air, being permitted to escape only at a small opening, rushes out with a velocity proportional to the pressure and to the smallness of the aperture. The large engines for propelling the air to the blast furnaces are the grandest illustrations of this kind of machinery.

Belluæ (Lat.). The term by which Linnæus designated an order of Mammalia, nearly corresponding to the Pachyderms of Cuvier.

Belomancy (Gr. *Βελομαντία*). Divination by the flight of arrows, common to various Oriental nations, and especially observed by the Arabians. It has been performed in various modes: one of the most common is, to let fly arrows, with inscriptions on labels attached to them, and take for a guide the contents of that belonging to the arrow first found.

Belonite. The name given by Glocker and Von Kobell to Needle Ore.

Belotes. The edible nuts or acorns of *Quercus Granuntia*.

Beltane or **Beltin** (said to be the 'fire of Bel' or Belus). May-day, and the traditional Celtic customs attached to it. The month of May is thus called in the present Irish language. This day is particularly celebrated by the herdsmen in the Highlands of Scotland. The Beltane-fire, Beltane-cake, &c. are all observances retained at the present day.

Belts. A name given to the zones or bands which appear on the disk of the planet Jupiter. They are situated near and parallel to the equator of the planet, and are supposed to be produced by clouds in its atmosphere arranged

BENCH, COURT OF QUEEN'S

in parallel strata, by currents of wind, which, by reason of the rapid rotation of the planet, must in the equatorial regions blow always in the same direction.

Beluga. The species of whale (*Delphinus leucas*, Pallas) which, from its colour, is commonly called by the whalers 'white-fish.' It is confined to northern latitudes.

Belvedere (Ital. *a fine prospect*). In Architecture, a small building at the top of a house or palace, constructed, as the name implies, to obtain a view of the country.

Belvisiaceæ (*Belvisia*, one of the genera). A natural order of monopetalous Exogenous plants related to the *Myrtacæ*. They are shrubby or arborescent plants, with alternate leaves and axillary almost sessile flowers, remarkable for the concentric rings of stamens. One of the species, *Napoleona imperialis*, comes from tropical Africa.

Bembex (Gr. *βέμβηξ*). A genus of Hymenopterous aculeate insects of the tribe *Fossorcs*, or burrowing sand-wasps; raised by Dr. Leech to the rank of a family (*Bembecidæ*), and including the genera *Bembex* proper, *Monedula*, and *Stizus*. Head transverse, with the upper lip exposed; tongue long, legs short; the brachia of the female furnished at the sides with very strong spines for burrowing in the sand. For the habits of this family, see *Fossorcs*.

Bembidium. A name applied by Latreille to a genus of Coleopterous insects, of the tribe *Carabidæ*. Now raised to the rank of a family (*Bembidiidæ*), including the genera *Lymnæum* 1, *Cilicnemus* 1, *Tachys* 8, *Philochthus* 6, *Ocys* 3, *Peryphus* 16, *Notaphus* 9, *Sopha* 11, *Tachypus* 9, *Bembidium* proper 4. The figures refer to the number of indigenous species in each of the genera. The common characters of the group are, cubits notched, elytra rounded at the extremity, abdomen not pedicellate, external maxillary palpi terminated by a very minute and acute joint, antennæ sub-elongate. The *Bembidiidæ* are generally found in low and damp situations, are of very small size, and glitter with polished metallic colour.

Ben Nuts. The seeds of an Arabian plant called *Moringa aptera*; they yield an oil, called oil of ben, and have been employed in syphilitic diseases.

Ben, Oil of. The expressed oil of the nut of the *Moringa aptera*. This oil is remarkable for not becoming rancid by age; and as it is perfectly insipid and inodorous, it is used for extracting the fragrant of certain flowers, such as the jasmine, orange, &c. The same tree furnishes the *Lignum nephriticum*, supposed to be useful in certain affections of the kidneys.

Bench. In Surveying, a bench mark is the term applied to a mark showing the starting point of a long line of levels, and to similar marks affixed at convenient distances to permanent objects, to show the exact spot where the level was held.

Bench, Court of Queen's. [COURTS OF JUSTICE.]

BENCHERS OF INNS OF COURT

Benchers of the Inns of Court. In England are in each Inn a self-elected body, but usually comprising the Queen's Counsel, and some other selected barristers. They exercise the office of admitting students to the bar, and the power of expelling them; subject to appeal to the judges of the superior courts. [BARRISTERS.]

Bend. The curvature given in plan, or in elevation, to the outline of a part, or of the whole of a building, or of a line of road, or a canal. As the name implies, a bend may be either a simple or a compound curve; it may be either on one side only, or it may be an S-curve, though the latter would hardly be capable of being executed in a vertical building.

BEND. In Heraldry, an ordinary bounded by parallel lines, equally distant from the line joining the dexter base to the sinister chief. It contains the fifth part of the escutcheon if charged, and the third if not charged. The bend sinister, descending from the sinister chief to the dexter base, is the difference which denotes bastardy, being borne on the paternal escutcheon of the bastard.

BEND. The general Sea term for fastening anything; as to bend one rope to another, the cable to the anchor, a sail to a yard or gaff. Certain knots are called *bends*; as a carrick bend, a fisherman's bend, &c.

Bends or Wales. A certain number of thick planks of the ship's side, from the water upwards.

Benedictine Monks. In Ecclesiastical History, bodies of men living under the monastic rule of St. Benedict. Up to his time the monasteries had been chiefly independent units; Benedict introduced into the monastic life a systematic organisation, and this change was of the utmost importance in the period of barbaric invasions which followed its institution. Benedict's first house was founded at Subiaco early in the 6th century; but the inroads of the Goths compelled him to remove it to Monto Cassino, whence his rule was rapidly extended over Europe. To this order belonged Gregory the Great, and the band of monks who with Augustine at their head were sent by that pope to effect the conversion of England. In later times the order became illustrious for the number of learned men whom it reckoned amongst its members. Bede in England was only the precursor of men (like Lanfranc, Alcuin, Bernard) yet more prominent in the world, whether of theology, politics, or letters. (See Milman, *History of Latin Christianity*, book iii. ch. vi.)

Benefice (Lat. *beneficium*). A word denoting church preferments of every class, except bishoprics: they may be with or without cure of souls: but the term is usually confined to what are popularly called 'livings,' as distinguished from dignities. Under the Romans, certain grants of lands made to the veteran soldiers were called *beneficia*; and the same term was applied at the commencement of the feudal system to estates conferred by the sovereign and held under him: which after-

BENEVOLENCE

wards assuming a hereditary character, became 'fiefs,' properly so called. In the middle ages the popes assumed the power of feudal lords with reference to ecclesiastical 'patronage,' and the term *beneficium* was hence applied to livings, &c. on the assumption that they were held under the pope as a superior lord. It was the assertion of this claim by Innocent III. and his successors which roused the jealousy of the European sovereigns, especially those of England and France, and led to those long quarrels between the temporal and spiritual power in Europe, which cannot be said to have terminated even in the Reformation.

Benefit of Clergy. In Law, originated in the immunities from municipal jurisdiction enjoyed in many states of Europe by the Roman Catholic clergy during the middle ages. When a person indicted in England for certain offences (such, generally, as subjected the offender to capital or corporal punishment), excepting high treason, pleaded that he was a clerk or clergyman, and claimed privilege, he was 'demanded' by his ordinary: a jury was summoned, and he was tried; and, according to their verdict, delivered to the ordinary as acquit or convict, to undergo canonical purgation, and to be discharged or punished according to the result of such purgation. The proof of clergy, at first strictly required, was at last so relaxed, that it was only necessary for the offender to show that he was able to read. The bishop's commissary was present, to decide whether or not he passed the test satisfactorily. This loose mode of acquiring the privilege was first restricted by the stat. 4 Hen. VII. c. 13, which provided that offenders who had been allowed their clergy should be 'burnt in the thumb,' and if they claimed it a second time, be required to give proof of being actually in orders. By 18 Eliz. c. 7, the second trial by purgation before the ordinary (which had become a mere fiction) was abolished, and the judges were empowered to imprison the person who had benefit of clergy for a year, if they thought proper. By various subsequent statutes, the burning in the hand was commuted for transportation, whipping, &c., at the discretion of the judges; and the benefit was taken away altogether from a number of statutable felonies. By 5 Anne c. 6, the ceremony of reading was abolished, benefit of clergy being granted indiscriminately to all entitled to it; and finally by one of the enactments commonly called Peel's Acts (7 & 8 Geo. IV. c. 28, s. 6) benefit of clergy was abolished altogether.

Benefit Societies. [FRIENDLY SOCIETIES.]

Benevolence. In English History, a species of tax levied by the sovereign. As its name implies, it was nominally a gratuity; but was, in point of fact, exacted as a forced loan, with or without the condition of repayment, under the reigns of the Plantagenet kings. Under a statute of Richard III. benevolences were declared occasionally, by means of circulars under the privy seal, by his successors. By 13 Ch. II. stat. 1, c. 4, no voluntary aid cau

BENGAL STRIPES

be raised on behalf of the king without the authority of parliament; and the general illegality of levying money for the use of the crown without such authority was declared in 1688 by the Bill of Rights.

Bengal Stripes. Cotton cloth woven with coloured stripes. Gingham.

Benic Acid. One of the solid constituents of oil of ben. [BEN, OIL OF.]

Benjamin. [BENZOLIN.]

Bent Grass. A species of *Agrostis*, the bent and creeping stems of which are very difficult to eradicate.

Bent Timber. Of late years much attention has been paid to the subject of bent timber on account of its strength and economy. There are two ways in which this operation is effected; viz. either by bending the timber whole, or by bending it in planks, which are then put together in pieces of any required thickness; both of them have been used for ship and for bridge building. When timber is bent whole, the requisite curvature is given by steaming the plank, and weighting down the side intended to receive the curvature; but the objection to this plan is, that steaming is apt to impair the durability of the wood, and the radius of curvature must be always very flat. It was to avoid these objections that the system was introduced of cutting the logs into planks, and bending them to the required curvature, as in several of the railway bridges and station roofs. In practice, however, it was found that the timber so bent remained sufficiently elastic to admit of considerable movement under the rolling weights of a train, and consequently opened at the joints, and allowed water to act upon the interior. All the bridges where these beams were used have decayed; but in sheltered positions they have stood admirably, provided they were not exposed to any deteriorating effects arising from the deformation under the rolling load. It is to be observed that the bent timber planks retain a much greater degree of elasticity than the whole timber so managed; and that they are also more likely to retain the original strength of the wood itself. Colonel Emy, of the French Génie Militaire, had the merit of introducing the system of bending the planks on the flat, and he published a treatise upon the subject in his work, *Sur la Charpenterie*, to which and to some articles by Nevier in the *Annales des Ponts et Chaussées*, No. 3 of the year 1831, the reader is referred for the mechanical theory of their resistance. Bent timber is largely used in the form of natural grown timber, in ship-building; but its use is becoming more and more rare, on account of the difficulty of obtaining natural growth wood for that purpose, which has led to the adoption of other forms.

Bents. The withered stalks of grasses standing in a pasture after the seeds have dropped.

Benzole Acid. This acid forms a constituent of many balsams; it is generally obtained by heating benzoin, and collecting the

BERBERY

acid vapours which are evolved and condensed in brilliant acicular crystals. It is a compound of carbon, hydrogen, and oxygen = $C_{11}H_8O_3.HO$. Its combinations are called *Benzoates*.

Benzole Alcohol. A heavy colourless oil resulting from the action of a spirituous solution of potash on hydride of benzoyl. It bears the same relation to benzoic acid that vinic alcohol does to acetic acid.

Benzoin. The resinous exudation of the *Styrax Benzoin*, a tree which is a native of Sumatra. Benzoin is a combination of resin and *benzoic acid*. It has a mottled or amygdaloid texture, and is composed of a mixture of brown and white parts. It has a fragrant odour.

BENZOLIN. A genus of *Lauraceæ* found in India and North America. *B. odoriferum*, a deciduous bush of North America, furnishes an aromatic stimulant tonic bark; and its berries yield an aromatic oil. This plant has been known as *Laurus Benzoin*.

Benzole. A compound of carbon and hydrogen, originally discovered by Faraday amongst the products of the destructive distillation of whale oil. The same compound was produced by Mitscherlich from *Benzoic acid*. It consists of 12 atoms of carbon, combined with 6 of hydrogen, and may be considered to be the hydride of the radical phenyl ($C_{12}H_5 + II$). It has a peculiar aromatic odour, boils at 176° , and concretes into a crystalline solid at 32° , a property which enables it to be separated from other hydrocarbons, which remain liquid at low temperatures. Benzole occurs amongst the products of the distillation of coal tar. One, two, or three atoms of hydrogen in benzole may be replaced by bromine, chlorine or peroxide of nitrogen. Nitrobenzole is now largely used as a source of aniline in the preparation of the so-called coal-tar colours.

Benzophenone. A combination of the radicals benzoyl and phenyl. It is crystalline, and is produced on distilling benzoate of lime with quicklime.

Benzoyl or Benzule (from benzoin, and *ἄη, matter*). A compound of carbon, hydrogen, and oxygen, = $C_{14}H_8O_2$, regarded as the base of benzoic acid; but the term is more appropriately applied to the radical hydrocarbon, $C_{14}H_8$.

Beraunite. A hydrated phosphate of peroxide of iron, occurring foliated and radiated, of a hyacinth-red or reddish-brown colour, at Huel Jane in Cornwall, in scaly, brittle masses; and near Beraun in Bohemia.

Berberidaceæ. A natural order of thalamifloral polypetalous Exogenous plants, named after *Berberis* or Berbery, which is in fact the most important genus it contains.

Berberine. A yellow bitter principle, contained in the alcoholic extract of the root of the berbery tree.

Berbery (Lat. *berberis*). A spiny shrub, bearing yellow flowers, and succulent one-celled edible fruit, growing in racemes. It is one of a genus in which the fruit is universally fleshy

BERENGELITE

and acid, although often less so than in the common kind, *Berberis vulgaris*. Some of the species have pinnated leaves, many are evergreens, and several have purplish-black fruit; even the common sort has a variety of this description, as well as others with pale yellow and stoneless fruit. There is an idea among country people that a berbery bush brings blight to a wheat field; but the parasitical fungus which attacks the berbery is altogether different from that which produces the mildew of wheat. The species with pinnated leaves have been called *Mahonia*.

Berengelite or Berengela Resin. A bituminous mineral allied to Gnyaquillite, found in amorphous masses of considerable extent, forming a sort of lake, in the province of St. Juan de Berengela in Peru, like the pitch-lake of Trinidad.

Bergamot, Essence of. The essential oil of the rind of a small pear-shaped fruit, the produce of the *Citrus Limetta Berganum*. It is much used as a perfume, and apt to be adulterated with the oils of orange and lemon peel, and with alcohol.

Bergaptene. A solid body occurring as a deposit in oil of bergamot.

Bergmannite. A brick-red or greyish-white fibrous variety of Mesotephe occurring massive in Zircon-Syenite near Brøvig in Norway. Named after the German chemist Bergmann.

Berlin Blue. [PRUSSIAN BLUE.]

Berm (Fr.). In Fortification, a narrow level space, two or three feet wide, along the exterior slope of a parapet, to prevent the mass of earth and other materials of which it is composed from falling into the ditch.

Bernoulli's Numbers. A series of numbers first used by James Bernoulli, Professor of Mathematics at Basle (1687). In the theory of mathematical series they are of great importance, are usually represented by the letters $B_1, B_2, B_3, B_4, B_5, \&c.$, and have the values $\frac{1}{6}, \frac{1}{30}, \frac{1}{42}, \frac{1}{30}, \frac{1}{42}, \&c.$, the general, or n^{th} Bernoullian number, B_{2n-1} , being the coefficient of

$(-1)^{n+1} \frac{1.2...2n-1}{12...2n-1}$ in the development of $(e^x - 1)^{-1}$. The theory of these numbers will be found in the works of Euler and Lacroix on *The Differential Calculus*. The values of the first twenty-five of them are given in the *Penny Cyclopædia* (art. 'Numbers of Bernoulli').

Berosus. In Entomology, a genus of Coleopterous insects of the family *Hydrophilidae*. They inhabit ponds, in which they may often be seen swimming in an inverted position.

Berries of Avignon (*Graines d'Avignon*). The fruit of the *Rhamnus infectiorius*, generally known under the name of *Persian Berries*. They are grown in Provence, Languedoc, and Dauphiné, and another variety comes from Persia. They contain a peculiar principle which has been termed *Rhamnin*, and which acquires a yellow colour by exposure to air.

Berthierite. A double sulphide of antimony and iron found in indistinct elongated

BESIMEN

prisms or confusedly lamellar masses, of a dark steel-grey colour, near Padstow in Cornwall; also in Auvergne, the Vosges, Saxony, and Hungary. Named after Berthier, by whom it was originally discovered.

Bertholletia (named in memory of Berthollet). A genus of *Lecythidaceæ*, one species of which, the *B. excelsa* of botanists, produces what are commonly called Brazil nuts. It is one of the largest trees of South American forests. The hard-shelled fruit is roundish and about six inches in diameter, and contains about two dozen of elongated wrinkled triangular seeds which are the 'nuts' of the shops. These are imported in considerable quantities from Para, and are hence sometimes called Para nuts. The seeds yield by pressure a bland oil, used by watchmakers and artists.

Beryl (Lat. beryllus, Gr. *Βήρυλλος*). A variety of Emerald. The crystals (six-sided prisms of very variable dimensions, but usually much larger than those of the Emerald) are generally blue or yellow, but some are colourless. When of clear tints of sea-green or sky-blue, they are called by the jewellers *aqua-marines*. The Beryl is one of the few minerals which contain the earth *glucina*, and consists of 67 per cent. of silica, 19 of alumina, and 14 of glucina. Gigantic crystals are met with in North America at Acworth and Grafton in New Hampshire, and at Royalston in Massachusetts. Very fine crystals are also brought from Dauria on the frontiers of China, from Siberia, and Brazil. In Britain, Beryls are found in Cornwall at St. Michael's Mount, in small bluish crystals in the parishes of Mabe and Constantine, and amorphous at Huel Cock near St. Just. In Ireland very fine specimens, mostly of a fine blue colour and sometimes quite transparent, are met with in the Mourne Mountains, county Down, and in other localities in the counties of Dublin and Wicklow; in Scotland they occur in the granite and gneiss of Cairngorm, and in the primary limestone of Portsoy in Banffshire, Kinloch Rannoch, Mount Balloch near Braemar, &c.

Berzelianite. A selenide of copper of a silver-white colour and metallic lustre, generally found in minute seams traversing Calc Spar, or as dendritic delineations of a black colour, owing to the decomposition it undergoes from exposure to the air. It occurs in the copper mine of Serickerum in Sweden, and near Lehrbach in the Harz. Named after the Swedish chemist, Berzelius.

Berzelite or Berzelite. Magnesian Pharmacolite. [KÜHNITE.]

Berzelino. A mineral, with nearly the same composition as Leucite, found massive, and in extremely minute octahedral crystals, which are white, grey, or colourless, and have a vitreous lustre, in peperino near Rome, and also at Galloro, near La Riccia, in an augitic rock. Named after Berzelius.

Besimen. An obsolete term for the spores or seeds of the lowest kinds of plants, especially of *Algae*.

BETA

Beta (Celt. *bett*, *red*). The chenopodiaceous genus which comprises the Beet, Mangold Wurzel, &c. [BEET.]

Betel. The leaf of the Betel or Siriboa Pepper, which is chewed by the inhabitants of many parts of India, along with a nut of the areca palm tree and lime. This mixture is acrid and narcotic, and stains the saliva red. The fruits of *Areca Catechu* are called Betel nuts.

Bethylus. In Entomology, a genus of Hymenopterous insects of the family *Proctotrupidae*.

Béton. The French name for Concrete; but as the concrete so made is essentially different from the stuff made under that name by English builders, it may be as well to retain the distinction in names, and to express by the latter the English concrete, and by the former the French béton. This consists, then, of an hydraulic lime properly slaked by itself, and presented in that state to the sand, so that the process of hydration may commence before it is mixed with the ballast which is subsequently added, by being turned over with the mortar on a boarded floor, and then run into the trench and well rammed. In fact, the object of concrete-making being to prepare a rough description of masonry composed of ballast and mortar, this method of making it must be the most efficacious, especially when the material has to be applied under water. In this case it may often happen that special precautions are required for conveying the béton to its intended position, because the lime may become detached from the other elements in its passage through the water. To prevent this, closed boxes are used, which are only opened when the mixture reaches its destination. The quantity of lime required for the preparation of a béton may vary with the circumstances of its use, from one of lime to $2\frac{1}{2}$ or 3 of sand, mixed with one proportion of mortar to three of ballast; evidently the quality of the lime has much to do with the proportions, and it is thus that they are made to vary. [CONCRETE; LIME.]

Betrothment (A.-Sax. *troth*, *truth*). A mutual compact between two parties, by which they bind themselves to marry. Betrothment was a legal contract by the Roman law, as it now is in various continental countries. In Germany, betrothments are either public, with the consent of relations and presence of witnesses; or private (clandestine), which in some countries are void; in others, although valid as contracts, punishable as misdemeanours. Public betrothment induces (where it is recognised as a legal ceremony) the obligation to marry. But according to modern practice an action for damages is almost the only way of enforcing it; a small fine or imprisonment being the utmost criminal penalty for the violation of the engagement.

Betulaceæ (*Betula*, one of the genera). A small natural order of catkin-bearing monochlamydeous plants, containing the Birch, after which it takes its name, and also the Alder.

BEZOUTIAN

The order formed part of what were formerly called *Amentacea*, or catkin-bearers.

Betuline. A resin contained in birch bark.

Beudantite. A hydrous silicate of lead and peroxide of iron with phosphate of peroxide of iron. It occurs in small black and brown rhombohedrons at Horrhausen and Montabaur (Dernbach), in the district of Nassau on the Rhine, and at the Glendore iron mine, near Cork. The crystals from the first locality have the phosphoric acid almost wholly replaced by arsenic acid. Named after Beudant, the French mineralogist.

Bevel (Fr. *beveau*). In Architecture, an instrument designed to take angles. One side of a solid body is said to be bevelled with respect to another, when the angle contained between their two sides is greater, or less, than a right angle. The term *splay* is nearly synonymous with *bevel*; but it is applied to openings which have their vertical sides sloped for the purpose of enlarging the opening.

Bevel Angle. A term used among artificers to denote an angle which is neither a right angle nor half a right angle.

Bevel Gear. In Mechanics, a species of wheel work, in which the axes of two wheels, working into each other, are neither parallel nor perpendicular, but inclined to one another at a certain angle. Wheels of this description are also called conical wheels, because their teeth may be regarded as cut in the frustum of a cone. [WHEEL.]

Bey or Beg. A Turkish and Tartar title of dignity, used with no very accurate application for lord, prince, or chief, and frequently subjoined to the proper names of persons of rank.

Bezant. A gold coin struck at Byzantium (Constantinople): it varied in weight and in value. Bezants appear to have been current in England from the tenth century to the time of Edward III. Some of them weighed about twenty grains. According to Camden, a piece of gold which was anciently offered by the king on high festivals was called a *bizantine* and valued at 15*l*. There were also white or silver bezants.

BEZANT. In Heraldry, a circle, or. The name is derived from the gold coin. It was probably introduced into coat armour by the Crusaders.

Bezoar. A Persian word denoting poison, and applied to certain intestinal concretions of animals, called bezoar-stones, which are supposed to possess poisonous powers.

Bezoar Mineral. An old preparation of oxide of antimony.

Bezoutian. A term first employed by Sylvester (*Phil. Trans.* 1853, and *Phil. Mag.* vol. vi. 1853) to denote the *n*-ary quadric whose discriminant is the symmetrical determinant obtained by eliminating, according to Bezout's abridged method [ELIMINATION], the variables from two binary quantities of the same degree (*n*). The (*n*-1)-ary quadric whose discriminant coincides with that of a given binary

BEZOUTICS

n-ic is also sometimes called the Bezoutiant of the given quantic, though Sylvester referred to it as the Bezoutoid. (Salmon's *Higher Algebra*.)

Bezoutics. [ELIMINATION.]

Bi (Lat. *bis*, *twice*). Signifies, when attached to other nouns, two, twice, or double; as bicarbonate of potash, a compound of potash with two atoms of carbonic acid; bilocular, two cells; bivalve, two valves, &c.

Biarticulate (Lat. *bis*, *two*, and *articulus*, *joint*). Applied in Entomology to the antennæ of insects when they consist of but two joints, and also to the abdomen under the same circumstances, as in the *Nycteria biarticulata*.

Biauriculate (Lat. *bis*, and *auricula*, *an auricle*). In Comparative Anatomy, signifies a heart with two auricles, as in most bivalve molluscs, and in all reptiles, birds and mammals.

Bibbs. In Naval language, are brackets bolted to the masts for the purpose of supporting the cross-trees.

Bible (Gr. τὰ βιβλία). The volume containing the collected books of the Old and New Testaments. The Greek word in primitive use was ἡ γραφή, or τὰ ἱερὰ γράμματα; and τὰ βιβλία is not found till the fifth century. St. Jerome (circa 400) gives the name *Bibbia* to his Latin version of the Scriptures; and it is from the Latin that the word *Bible* has been introduced into our language. It occurs in Piers Ploughman and Chaucer; and being adopted by Wiclif, it has been ever since strictly confined to the sacred volume.

Bible Society, British and Foreign. [SOCIETIES.]

Biblical History and Literature. The accounts of the books of the Jewish Scriptures antecedent to the captivity are few and indistinct; but they are referred to under the titles of 'the law,' 'the books of Moses,' and 'the books of the law of Moses,' by Daniel (ix. 11), Ezra (vi. 18), and Nehemiah (viii. 1): there are also other passages from which it may be inferred, independent of the internal evidence of the books which we possess, that there existed such from an early period.

The canon of the Old Testament appears, however, to have been settled about fifty years after the return from the captivity, by the authority of Ezra and the prophets of his day; the books of Nehemiah, Malachi, and Ezra himself being subsequently added. The sacred writings which came in later times to be incorporated in the collection of the Jewish Scriptures are known by the name of Apocrypha, or secret: they were undoubtedly held in respect by the Jews, and by the Christians afterwards; but Protestants deny that their authority was ever placed on the same footing as that of the canonical Scriptures.

At a later period we find passages in the New Testament, in Philo, and most distinctly in Josephus, to prove the fact of this collection of the Scriptures into a volume. The books themselves are first specified by Origen, who enumerates twenty-two, in which number he coincides with Josephus. His list embraces

BIBLICAL HISTORY

all that we consider canonical, and rejects the Apocrypha.

The early versions which illustrate the question of the antiquity of the Hebrew Scriptures are the Samaritan Pentateuch, and the Septuagint or Greek translation. It is not to be supposed that the Samaritans would have adopted and translated the books of the Jews, unless they had been received prior to the separation and enmity of the two peoples, the period at latest of the return from the captivity. The Samaritan Pentateuch now extant is said to be a version from the earlier Hebrew Samaritan into the more modern Samaritan, and was made before the time of Origen. The part of the Septuagint which comprises the Pentateuch was made about the year B.C. 285; the translation of the other books into Hellenistic Greek appears to be of different and somewhat later dates.

Next in order to these may be mentioned the versions of the Old Testament in the earliest periods of Christianity, which are important, not as assisting us to ascertain the antiquity of the original, but as contributing to our knowledge of the genuine text. These may be divided into three classes.

I. The Oriental, comprising:—

The Syriac or Peshito (literal), from the Hebrew, about the end of the first century—embracing both the Old and New Testaments.

The Coptic, from the Septuagint—between centuries two and five. This embraces also the New Testament.

The Ethiopic, from the Septuagint—in the fourth century: embraces the New Test.

II. The Latin, or Western:—

The Italic, from the Septuagint, in either the first or second century; only fragments remain: it embraced also the New Testament.

The Vulgate, made from the Hebrew by Jerome, A.D. 390. This translation is considered an ultimate authority by the church of Rome.

The Gothic Version of Ulphilas, which was made from the Greek of both the Old and New Testaments, in the fourth century, has not come down to us entire. Only a small part is in print.

III. The Greek, comprising:—

The version of Aquila.

— of Theodotion.

— of Symmachus.

All translated from the Hebrew; all of or near the second century; all exist only in the fragments of the Hexapla or combination of six versions by Origen.

The genuineness of the Hebrew text was preserved after the destruction of Jerusalem by the sedulous care of learned academies which flourished at Tiberias, Babylon, and other places, from the first to the twelfth centuries. The date of the Masora is generally fixed about the fifth century. This work consisted of a most

BIBLICAL HISTORY

minute enumeration of the sections, verses, words, and letters of the Scriptures; which has been so successful in fixing the genuine reading, that although there were discovered upwards of 800 discrepancies between the Oriental and Occidental Recensions, they all relate, with one single exception, to vowel points, and are of no kind of importance. For an account of the labours of the early Jewish schools of criticism in the interpretation of the Hebrew text, see TALMUD.

The integrity of the text of the New Testament has been established by the collation, wholly or in part, of 674 manuscripts existing either entire or in fragments. These have been classified by modern critics according to recensions or families, the most simple of whose systems, and the most approved, is that of Scholz, who considers all the variations that exist in these MSS. to be resolvable into their having been transcribed from Constantinopolitan or Alexandrian exemplars. The former he considers to have been from the earliest times the most strict and faithful recension. It was that which was principally used in the liturgical offices of the East; and its fidelity is argued from the exact uniformity of all the MSS. which can be traced historically to a Constantinopolitan origin. This may be accounted for by the authority inherent in the text received in the centre of the imperial power and of the patriarchal jurisdiction. It is also consistent with the minute care with which the rites of the Constantinopolitan church were enjoined by its missionaries upon their converts; and also with the character of the Greek fathers, who present much greater exactness and uniformity in their quotations of the New Testament than the African. On the other hand, the Alexandrian copies have been written with a considerable degree of carelessness, and do not appear to have been intended, even in their own country, for reading in public service. They are said to exhibit the rash and speculative spirit of the theologians of the Alexandrian church. The former of these recensions has been adopted in the Syriac, Gothic, and Slavonic versions. It is that also which forms the basis of our modern texts. The latter was followed by several Latin, the Coptic, and Ethiopic translations. Erasmus conceived the idea of the Greek text having been purposely corrupted to suit the Vulgate, and assigns the council of Florence in 1439 as the authority by which this transaction was effected. This opinion continued to be held under the title of the *Fœdus cum Græcis*, with more or less discussion till modern times, by which it seems to be very generally rejected as untenable. It is known, on the contrary, that in the compilation of his translation, which bears the name of the Vulgate, the existing Latin version was corrected by Jerome from the Greek.

Bibliography (Gr. βιβλιογραφία). The science of books. The knowledge which is required to classify books, according to the various subjects on which they treat, has been

BIBLIOGRAPHY

termed intellectual bibliography; that of the external peculiarities of books—the number of editions through which they have passed, the printer or publisher, their date as to time and place, their form and size, and their comparative completeness, correctness, typographical beauty, and rarity—material bibliography. The first branch borders closely on the province of criticism; for the most valuable bibliographical works, being what are termed in French ‘catalogues raisonnés,’ are those in which the lists of books are accompanied with some remarks on the character of their contents. The best ‘catalogue raisonné’ is, perhaps, that of the French *Bibliothèque Royale*, 10 vols. folio, 1739–1753. The catalogue of the library of the University of Göttingen is said to be the most complete of this kind, but we believe it is still in MS. The catalogue of the library of the Writers to the Signet Edinburgh is the best English ‘catalogue raisonné.’ It is arranged upon De Burman’s plan, and was published in 1805, in 4to. The second branch of bibliography has been of late years cultivated with all the ardour attached to a fashionable and somewhat eccentric pursuit. The lovers of rare editions and curious copies of works, from being, to borrow a French term, ‘bibliophiles,’ formed some years ago a peculiar sect entitled ‘bibliomania,’ in whom the fancy for books had become a passion, like those of Dutch speculators for tulips and pictures. Many works of novel and curious research in this department of literature have been recently produced to guide their taste, and gratify their appetite.

The following list contains a selection from among the most valuable works which we possess, in different departments of bibliography. But many of them, from the critical matter which they contain, may be considered to belong to the history of literature, as well as of books and editions.

I. Introductory Works on the Science of Bibliography.

- Paignot*, Manuel Bibliographique, 8vo. Paris, 1800.
Peignot, Dictionnaire Raisonné de Bibliologie, 3 vols. 8vo. Paris, 1804. An excellent work on the science.
Achard, Cours de Bibliographie, 3 vols. 8vo. Marseille, 1807. Not very methodically arranged.
Horne, Thomas Hartwell, Introduction to the Study of Bibliography, 2 vols. 8vo. Lond. 1814.
Denis, Einleitung zur Bücherkunde, 2 vols. 4to. Vienna, 1777, 1778; 2nd edit. 2 vols. 4to. Vienna, 1795.
Boulard, Traité Élémentaire de Bibliographie.

II. Bibliography of the Oriental and Classical Languages.

- Gesner*, Bibliotheca Universalis, sive Catalogus Scriptorum Lat. Gr. et Hebr. tam extantium

BIBLIOGRAPHY

- quam non extantium. Folio, Tigur. 1545. The best edition is that of Frisius, folio, Tigur. 1683. The works are arranged according to the names of the authors. It is mainly confined to works in the Hebrew, Greek, and Latin languages. It was one of the earliest attempts at classical and Hebrew bibliography.
- Clarke, Dr. Adam*, Bibliographical Dictionary, 6 vols. 12mo. Liverpool and Manchester, 1802-4. See also his Bibliographical Miscellany, 2 vols. 12mo. Lond. 1806.
- Long, James le*, Bibliotheca Sacra, 2 vols. 8vo. Paris, 1709. An enlarged edition was published by Desmolls in 2 vols. folio. Paris, 1723. Another edition was begun by Masch in 1778, and between that and 1790 5 vols. 4to. were published, but the work was unfinished.
- Fabricius*, Bibliotheca Græca, edited by Harles, 12 tom. 4to. Hamburg, 1790, 1809.
- Fabricius*, Bibliotheca Latina. By Ernesti. 3 vols. 8vo. Lips. 1773, 1774.
- Fabricius*, Bibliotheca mediæ et infimæ Latinitatis. By Manso. 3 vols. 4to. Batav. 1759.
- Harwood's* View of the various Editions of the Greek and Roman Classics, 4th edit. (the best) 12mo. Lond. 1790.
- Dibdin's* Introduction to the Knowledge of rare and valuable Editions of the Greek and Latin Classics, 2 vols. 8vo. 1827.
- Moss's* Manual of Classical Bibliography, 2 vols. 8vo. 1825.
- Degli Autori Classici Biblioteca portabile* (Boni and Ganba), 2 vols. 12mo. Venice, 1793.
- III. *Bibliography of Particular Sciences and Branches of Literature.*
- Lipenius*, Bibliothecæ (Theologica, Juridica, Philosophica, Medica), 6 vols. fol. The Juridica by itself has been reprinted, with supplements, &c. in 4 vols. Leipsic, 1775-89. The whole collection passes under the title of Bibliotheca Realis.
- Meusel*, Leitfaden zur Geschichte, &c., 2 vols. 8vo. Leipsic, 1799.
- Bibliothèque Historique de la France, 6 vols. folio, 1768, 1778.
- Murhard*, Bibliotheca Mathematica, 5 vols. 1797-1805.
- Dryander*, Catalogus Bibliothecæ Historico-Naturalis Josephi Banks (a general account of books on natural history), 5 vols. 8vo. Lond. 1796-1800. This valuable library is now in the British Museum. The catalogue was compiled with great ability.
- Lalande*, Bibliographie Astronomique, 4to. Paris, 1803.
- Boucher de la Richarderie*, Bibliothèque de Voyages, 6 vols. 8vo. Paris, 1808.
- IV. *Bibliographical Works on Rare Books, Typographical Antiquities, Early Editions, &c.*
- Fogt*, Catalogus Historico-Criticus Librorum rariorum, &c., 8vo. Hamb. 1732. The 6th, and best edition, 8vo. Nuremb. 1793. A very valuable work.
- Gerdesius*, Florilegium Librorum rariorum, 3rd and best edition, 8vo. Groning. et Brem. 1763.
- Clement*, Bibliothèque curieuse, ou Catalogue Raisonné des Livres rares, 9 vols. 4to. 1750-60. A minutely critical work.
- Baur or Baverus*, Bibliotheca Librorum rariorum universalis, 7 vols. 8vo. Nuremb. 1770-91.
- Maittaire*, Annales Typographici ab Artis inventæ Origine ad Annum MDCLXIV. 5 vols. 4to. Hag. Com. Amstelod. et Londini. 1719-41. Several supplements have been published.
- Panzer*, Annales Typographici ab Artis inventæ Origine ad Annum MD., &c., 11 vols. 4to. Nuremb. 1793-1803. It is carried down to 1536. It is a work of the very first importance, but is rendered more complete by a subsequent work of his, published in German, called Annals of Ancient German Literature, &c., 2 vols. 4to. Nuremb. 1788, 1806. A supplement to vol. i. was published in 1802.
- Ames's* Typographical Antiquities, first edition, 1749; republished by W. Herbert in 3 vols. 4to. 1790; and again by Dr. Dibdin in 4 vols. 4to. 1810-19.
- Dibdin*, Bibliotheca Spenceriana (a catalogue of books in the Spencer library, printed before 1500), 4 vols. imp. 8vo. (and 55 copies in 4to.). Lond. 1814-15. Well known, like most of the other works of this distinguished bibliographer, for the minuteness of its research and extreme beauty of embellishment.
- Santander*, Dictionnaire Bibliographique Choisi du Quinzième Siècle, 3 vols. 8vo. Bruxelles, An. xiii., 1805.
- De Bure*, Bibliographie Instructive, ou Traité de la Connaissance des Livres rares et singuliers, with supplements, in all 10 vols. 8vo. Paris, 1763, 1782. The most practically useful and elegant work on the subject, and one which has perhaps contributed more than any other to make the study of bibliography popular.
- Osment*, Dictionnaire des Livres rares, 2 vols. 8vo. Paris, 1768.
- Renouard*, Annales de l'Imprimerie des Aldes, ou Histoire des Trois Manuce, &c., 2 tom. 8vo. Paris, 1803. [ALDINE EDITIONS.]
- Lowndes*, Bibliographer's Manual. New edition by Bohn. A valuable work.
- V. *General Bibliographies, and Miscellaneous Works.*
- Watt's* Bibliotheca Britannica, 4 vols. 4to. Edin. 1824. This most useful and meritorious work contains a catalogue of works, arranged alphabetically, first under the head of writers, and then of subjects. It contains many foreign articles, but is chiefly devoted to English literature. A more complete and more critical work on English bibliography is

BIBLIOGRAPHY

among the greatest desiderata of the present day.

Querard, La France Littéraire. A very valuable catalogue of French works, in all departments of literature. Paris, 1828, &c.

Mazzuchelli, Gli Scrittori d'Italia, cioè Notizie Storiche e Critiche intorno alle Vite e agli Scritti dei Letterati Italiani. A work containing literary history and biography, with bibliographical science, 6 vols. fol. Brescia, 1753-63.

Potthast, August. Bibliotheca Historica Medii Ævi. Wegweiser durch die Geschichtswerke des Europäischen Mittelalters von 375—1500. Berlin, 1862. A very valuable work for the student of mediæval history.

Foppens, Bibliotheca Belgica, 2 vols. 4to. Brux. 1739.

Dictionnaire Bibliographique, 3 vols. 8vo. Paris, 1790.

Brunet, Manuel du Libraire, &c., 3rd and enlarged edition, 4 vols. 8vo. 1820. The best work on bibliography. A new edition is in course of publication (1863). Two supplementary volumes were published in 1832.

Morhof, Polyhistor, Literarius, Philosophicus, et Practicus, first edition by Fabricius, 2 vols. 4to. Lube, 1747. This is the best edition.

Saxius, Onomasticon Literarium, 7 vols. 8vo. Traj. ad Rh. 1776-90, and a supplementary volume in 1803.

Jöcher's German Dictionary is a useful work, and contains many works and authors unnoticed by other bibliographers; but the Bücher-Lexicon of Hensius, and that of Kayser, are the most complete modern compilations of this order.

Solkeby, Principia Typographica. Only two of the elements of bibliography discussed by him have been published, viz. Block Books and Paper Marks. The remainder of a labour of forty years is unfortunately still in MS.

Rich, O., Bibliotheca Americana nova; or, A Catalogue of Books in various Languages, relating to America, printed since the year 1700, in 2 vols. Vol. i. 1700-1800; vol. ii. 1801-1844. Lond. 8vo. 1835, 1846. There is a supplement to vol. i. dated 1841.

Duyckinck, Evert O., and George L. Duyckinck, Cyclopædia of American Literature, embracing personal and critical Notices of Authors, and Selections from their Writings, from the earliest Period to the present Day, with Portraits, Autographs, and other Illustrations, in 2 vols. imp. 8vo. New York, 1855.

Allibone, S. Austin, A Critical Dictionary of English Literature, and British and American Authors, living and deceased, from the earliest Accounts to the middle of the Nineteenth Century, containing 30,000 Biographies and Literary Notices, with 40 Indexes of Subjects, imp. 8vo. Philadelphia and London, 1859. Only vol. i., A to J, yet published.

BIFORINES

VI. Bibliography of Anonymous Works, and of Books privately printed.

Barbier's Dictionnaire des Ouvrages Anonymes et Pseudonymes, 4 vols. 8vo. 1822-25. Confined to works in the French and Latin languages.

Martin's Bibliographical Catalogue of Books privately printed, 8vo. 1834. A second edition of this valuable work has been published.

Bicalcarate (Lat. bis, and calcar, a spur). When a limb or part is armed with two spurs.

Bice. In Painting, a light blue colour prepared from smalt. From it, by a mixture with yellow orpiment, another colour is formed of a green hue, bearing the same name.

Biceps (Lat. from bis, and caput, head). When muscles have a double insertion, or arise by two heads.

Bicoligatæ (Lat. bis, and colligo, I bind together). In Ornithology, a term signifying the connection of all the anterior toes by a basal web.

Bicolor (Lat.). When an animal or part is of two colours.

Bicornis (Lat. from bis, and cornu, a horn). In Zoology, when an animal or part has two horns, or two hornlike processes. In Anatomy, when the uterus has two divisions, like horns, as in most quadrupeds.

Bicuspid (Lat. bis, and cuspis, a point). In Anatomy, when a part has two cusps, or pointed portions, as the bicuspid valve between the left auricle and ventricle. The term is also applied to a tooth with two points.

Bidentate (Lat. bis, and dens, a tooth). When an animal has but two teeth, as the *Delphinus bidens*; or when a part has two tooth-like processes.

Bieberite. A hydrated sulphate of cobalt and magnesia, which occurs in flesh-red and rose-coloured, translucent, friable stalactites, and in crusts investing other minerals, in the rubbish of old mines at Bieber near Hanau, and at Leogang near Salzburg.

Biennial (Lat. biennis, of two years' duration). A term applied to plants which grow one year and flower the next, after which they perish; they only differ from annuals in requiring a longer period to fruit in. Most biennials, if sown early in the spring, will flower in the autumn, and then perish, thus actually becoming annuals.

Bleating, Beestning or Colostrum. The first milk yielded by the cow immediately after the birth of the calf.

Bifarius (Lat. bifarius). Arranged in two rows; frequently applied to flowers and ovules.

Biforate (Lat. biforis). Having two perforations or apertures, as the anthers of a *Rhododendron*.

Biforines (Lat. biforis). Minute oval sacs found in the interior of the leaves of some Araceous plants. They taper to each end where they are perforated, and are apparently composed of two bags one within the other, the

inner bag being filled with the fine acicular crystals or spicules called raphides. When the biforine is placed in water it discharges its spiculae with considerable violence, first from one end and then from another, recoiling at every discharge, and eventually emptying itself, when it becomes a flaccid motionless bag.

Bifurcate (Lat. *bis*, and *furca*, a fork). When a part has two prongs like a fork.

Big or **Byg** (Dan. *byg*), also called **Bere**. The name applied in Scotland to *Hordeum Hexastichon*. It is a much hardier plant than barley, to which it is preferred in Scotland, as ripening more rapidly.

Bigamy (Lat. *bis*, and Gr. *γάμος*, marriage). The offence of contracting a second marriage during the life of the husband or wife, which, by the law of England, is felony, punishable by penal servitude, or imprisonment. Bigamy, by the canon law, signified a second marriage after the death of the first wife, or a marriage with a widow; and incapacitated the party contracting it from entering holy orders in the event of widowhood. [MARRIAGE, LAW OF.]

Bight (A.-Sax. *bilht*). Part of a rope between the ends; bight is also a shallow bay or hollow in the line of sea coast.

Bignoniaceae (from *Bignonia*, the typical genus: so called after the Abbé Bignon, a French man of letters, and the friend of Tournefort). A natural order of corollifloral didynamous Exogens, usually having a twining stem, large trumpet-shaped flowers, and a pod-like capsule with winged seeds. Some of them are trees of considerable size, and furnish timber valuable in the countries where it is produced; but the greater part are interesting only for the beauty of their flowers, in which respect this order yields to no other; indeed the *Bignonias* are probably the handsomest twining plants known. *Bignonia Chica* yields a red pigment, called Chica on the Orinoko, and much used by the natives for painting their bodies.

Biharite. The name proposed by Peters (after the mountain in which it is found) for a mineral from Werkstahl, near Retzbranya, which had previously passed for Agalmatolite.

Bijugate (Lat. *bis*, and *jugum*, a yoke). Composed of two pairs of any thing; a term applied to leaves pinnated with two pairs of leaflets.

Bikh, Bish or Bikhma. The root of a deleterious plant inhabiting Nepal. It was used by the natives of that country to poison their wells when the British troops invaded it. This plant is the *Aconitum ferox*, the poison of which, like that of all other Ranunculaceae plants, is volatile; and although highly dangerous when fresh, loses its activity when exposed to the air.

Bilabiate (Lat. *bis*, and *labium*, a lip). When a flower has all or any of its parts collected into two separate parcels or lips. Thus a calyx having two of its sepals collected into one parcel, and the others into a second parcel, or a corolla with its five petals adhering two and three together, is bilabiate.

Bilamellate (Lat. *bis* and *lamella*, a plate). When a part is divided longitudinally into two lamellae or plates; also, bearing two vertical plates.

Bilander (Fr. *bélandre*, Dutch *bij-lander*). An obsolete two-masted cargo vessel, remarkable for bearing her mainsail bent to the whole length of a yard passing fore and aft at an angle of 45° with the deck.

Bilberry. A small bush inhabiting the northern parts of Europe in mountainous situations, and bearing small black berries, which are eaten by country people under the names of whorts, hurts, &c., and are a favourite food of deer. It is the *Vaccinium Myrtillus* of botanists.

Bilboes. Long bars of iron, with shackles sliding on them, into which are placed the ankles of sailors who may be sentenced to be 'put in irons.'

Bildstein (Ger.). A mineral composed chiefly of silica and alumina with a little oxide of iron. [AGALMATOLITE.]

Bile (Lat. *bilis*). A fluid secreted in the liver, of a yellow colour and a nauseous taste, compounded of sweet and bitter; it sinks in water, and mixes with it in all proportions; it is slightly alkaline, and feels soapy. It contains a peculiar bitter principle, which has been called *picromel*, and a little free soda and saline matters. According to Berzelius, the solid constituents of bile amount to about one-tenth of its weight.

Bilge. The lower or flat part of the bottom of a ship on which she rests when aground. Mr. Wedgwood regards the word as connected with *Bulge* (*Dictionary of English Etymology*).

BILGE OF A CASE. The middle part between the ends, in which the bung-hole is placed.

Bilge Water. The water that collects in the bottom of a ship by leakage or otherwise. It has usually a peculiar and offensive smell. When a ship is tight, the bilge water when pumped up is dark; in a leaky ship, it comes up clear.

Bilged. In Nautical phrase, having the bottom stove in.

Bilgeways. Timbers which are employed in the launching of ships.

Biliary Calculi. Concretions which form in the gall-bladder (gall stones) or bile-ducts. They are generally composed of a peculiar crystalline fatty matter, which has been called *cholesterine*.

Bilifulvin. The yellow colouring matter of bile.

Biliphein. The brown colouring matter of bile, to which the colour of excrement is due.

Bilverdin. The green colouring matter of ox-bile.

Bill (Lat. *bullā*, the seal appended to a papal document or bull). A legislative measure introduced into parliament is so called until it has acquired the force of law by receiving the royal assent. Bills are either public or private; a distinction founded rather on usage and precedent, than on any exact definition. The immediate parliamentary consequence of the

BILL IN EQUITY

distinction is the payment of certain fees to the officers of the house, which are due by custom on private bills. According to Hatsell, this difference between private and public bills was recognised as long ago as 1607. It is a general rule of parliamentary proceeding, that the same bill or question cannot be twice offered in the same session. But at every stage of a bill, the whole of it is supposed to be before the house; and consequently if words have been inserted by way of amendment, the sense of the house may again be taken respecting them at a subsequent stage. [PARLIAMENT.]

Bill in Equity. In Law, is the proceeding whereby a suit in Chancery is commenced, being in the form of a petition addressed to the Lord Chancellor. [PLEADING IN EQUITY.]

Bill of Exchange. [EXCHANGE.]

Bill of Health. A certificate or instrument, signed by proper authorities, delivered to the masters of ships at the time of their clearing out from all ports or places suspected of being infected by particular disorders, certifying the state of health at the time that such ships sailed. Bills of health are of three kinds—*clean, foul, and suspected*, which are self-explanatory terms.

Bill of Lading. A document, subscribed by the master of a ship, acknowledging the receipt of goods intrusted to him for transportation, and binding himself (under certain exceptions) to deliver them to the person to whom they are addressed, in good condition, for a certain remuneration or freightage. Of bills of lading there are usually triplicate copies; one for the party transmitting the goods, another for the person to whom the goods are addressed, and the third for the master.

Bill of Quantities. In estimating the probable cost of a building, the abstract, or the résumé of the detailed calculations, is called the bill of quantities; it contains the amount of the separate items of the various trades, and is carried to the abstract, or the sums of the same.

Bill of Rights. In Law, the declaration delivered by the two houses of parliament to the prince of Orange, February 13, 1688, at the period of his election to the British throne; in which, after a full specification of various acts of James II. which were alleged to be illegal, the rights and privileges of the people were asserted.

Bill of Sale. In Law, a contract under seal, by which a man passes his interest in goods and chattels to another, and which does not require either valuable consideration or actual transfer of the goods to support it, as between the vendor and vendee; although as between the vendee and the vendor's creditors the absence of such consideration and transfer would in general be held indicative of fraud, and invalidate the contract.

Bill-board. In Navigation, an iron-shod stool on which the flukes of the anchor are stowed.

BILLIARDS

Billet (Fr. *billot*). In Heraldry, a bearing of which the origin is very uncertain; represented of an oblong square form, sometimes showing the thickness, and always with a flat surface. *Billetty*, or *semée* of *billets*, signifies that the escutcheon or charge is strewn over with these bearings, without regard to particular number or station.

Billet and Zigzag. A moulding frequently introduced in Mediæval Architecture, consisting of a torus ornamented by alternate chequers, like a staff cut into short lengths and disposed horizontally or around a moulding, and of another moulding composed of a series of small projections, arranged round a curve in alternate directions but in a consecutive manner.

Billiards (Fr. *billard*). A game played on a rectangular table, bordered by elastic cushions, generally about twelve feet long by six feet wide, with ivory balls, which being struck with the end of a stick, called a cue (French, *queue*), are caused to strike each other and are driven into holes at the angles and sides of the table, according to certain rules. Several different kinds of games are played, but the ordinary English one is as follows. Two players, opposed to each other, have each one white ball (distinguished from each other by a slight mark or spot on one of them); and there is a third ball—a neutral one—coloured red, always on the table. The player whose turn it is to make a stroke endeavours—first, as a condition precedent, causing his ball to touch one of the others—to produce one of four effects: (1) to make his ball *also* touch the third ball, which is called a *carambole* or *cannon*, and scores two points in his favour; or (2) to drive the red ball into a pocket, which counts three; or (3) to put his adversary's ball into a pocket, which is called a 'winning hazard,' and counts two; or (4) to put his own ball into a pocket, which is called a *losing hazard*, and scores two if made from the white, and three from the red ball. The same player continues till he fails to make a score, when the other takes his turn. If a player fails to cause his ball to touch one of the others, it scores one against him; and if he happen to put his ball into a pocket without its first touching one of the other balls, it scores three against him. The game is sometimes twenty-one, sometimes fifty, and sometimes one hundred points. After either of the white balls has been pocketed it must be placed, for its owner to begin again, within a certain division of the table, called 'balk,' and he is prohibited from aiming at any ball that may happen to lie in that space. After the red ball has been put into a pocket, it is replaced upon a certain spot marked on the table for that purpose. On the Continent losing hazards generally score *against* the player; and sometimes all hazards are abolished, the game being played for *caramboles* only.

Another game of billiards, called *Pool*, is played by several players, each of whom deposits a certain stake towards the pool and has a separate ball, the several balls being of dif-

ferent colours to distinguish them from each other. The players make strokes in turn, the object being to drive any of the opponents' balls into the pockets, and so clear them off the board; the last remaining wins the pool.

Billiards is a fine game, and very popular; to play it well requires highly cultivated qualities of eye and hand, and much judgment and practice. The points in which excellence of play is shown are: accuracy of aim; accurate graduation of the strength of the blow; just estimation of the angles of incidence and reflection, from both the balls and the cushions; modification of the effects by different modes of hitting the ball, and by giving it different directions and velocities of rotation; attention to the state of the score; judgment as to the proper object to try for; and prescience as to how the balls will remain after the stroke is completed. The mathematical rule 'that the angles of incidence and reflection are equal,' although useful in billiards as a general guide, does not fully apply, as the angle at which a ball will fly off from another ball, or from the elastic cushion, is considerably modified by the amount and direction of rotation possessed by the striking ball. A ball may strike the cushion perpendicularly, and yet if it has a horizontal rotation (caused by striking it on one side instead of in the centre), it will rebound at a very oblique angle. Great use is made by skilful players of this element of the game.

Billion (Fr.). In Numeration, denotes a million of millions, and is expressed by 1000000000000. The French use the same word to denote a thousand millions. The term is probably a contraction of *bis* and *million* whence the English signification, a million of millions, appears more according to analogy.

Bills of Mortality. Are accounts of the number of births and burials within a certain district in every week, month, quarter, or year. These were first compiled in London after the great plague of 1593; and ten years afterwards began to be returned weekly. Several of the parishes now included within the metropolis (as Marylebone and Pancras) are not within the bills of mortality. [MORTALITY.]

Bilobate (Lat. *bis*, and Gr. *λοβός*, a lobe). When a part is divided into two lobes, or obtuse processes.

Bilocular (Lat. *bis*, and *loculus*, a cell). Having two cells.

Bimaculate (Lat. *bis*, and *macula*, a spot). When an animal or part is marked with two spots.

Bimana (Lat. *bis*, and *manus*, a hand). The term applied by Cuvier to the highest order of Mammalia, of which man is the type and sole genus.

Bimedial (Lat. *bis*, and *medius*, middle). In Geometry, when two lines commensurable only in power (for example, the diagonal and side of a square) are joined together, the sum is irrational with respect to either of the two lines, and is called a *bimedial*.

Binary Arithmetic. A species of arithmetic, proposed by Leibnitz, and founded on the shortest and simplest progression; namely, that which terminates with the second cipher. In the binary notation, therefore, only two characters are required, 1 and 0, the zero having the power of multiplying the number it follows by two, as in the common notation it multiplies by ten. The number *one* is represented by 1; *two*, by 10; *three*, by 11; *four*, by 100; *five*, by 101; *six*, by 110; *seven*, by 111; *eight*, by 1000; *nine*, by 1001; *ten*, by 1010, &c. This method of notation, though it may be applied with advantage in the investigation of some properties of numbers, would be inconvenient for common purposes, on account of the great number of characters required, even when the numbers to be expressed are small. We will give an example from the *Encyclopédie Méthodique* of the method of expressing a number by the binary scale, and of finding the value of a number so expressed.

It is convenient to begin with forming a table of the powers of 2, namely, 2⁰, 2¹, 2², 2³, &c. They are 1, 2, 4, 8, &c. Suppose, now, it were required to express the number 230 by the binary scale. Seek in the table the greatest power of 2 contained in 230; it is found to be 128, which is the 8th number in the table; hence the expression will contain 8 ciphers, and the first on the left hand is 1. Subtract 128 from 230, the remainder is 102; the highest power of 2 contained in this is 64, which is the 7th number in the table. The second cipher will therefore be also 1. Subtract 64 from 102, and the remainder is 38. But the 6th number in the table is 32, which is less than 38; therefore the third cipher in the expression is still 1. Subtract 32 from 38, the remainder is 6; but the 5th number in the table is 16, which is greater than 6; therefore the 4th cipher of the expression is 0. The 4th number in the table is 8, which is also greater than 6; therefore the 5th cipher must also be 0. The 3rd number in the table is 4, which is less than 6; therefore the 6th cipher will be 1. Subtracting 4 from 6, the remainder is 2; but the second number in the table is 2, therefore the 7th cipher is 1. The last difference is zero; therefore the last cipher in the expression is 0. Collecting all these results, we find the number 230 is expressed in the binary scale by 11100110.

Next, suppose it were required to determine the value of the expression 110101 in the binary scale. As there are here 6 ciphers, we look for the 6th number in the above table, and find 32, which is the value of the 1st cipher. The following cipher represents the 2nd number, and is consequently equal to 16. The 3rd cipher is 0, and its value nothing. The 4th cipher corresponds to the 3rd number in the table, and represents 4. The 5th cipher is 0, and its value nothing. The last cipher corresponds to the first number of the table, which is 1. The whole expression, therefore, 110101, is equivalent to 32 + 16 + 4 + 1 = 53. It has been imagined, though on very slight

BINARY MEASURE

grounds, that traces of the binary notation are discernible among the early monuments of China.

For information on the subject of arithmetical scales, see Leslie, *Philosophy of Arithmetic*.

Binary Measure. In Music, that in which there are two even beats in a bar, usually called common time.

Binary Theory. A view which supposes all definite chemical salts to be combinations of two bodies. The two bodies may be simple radicals (elements) or compound radicals, or one of each class. Sulphide of potassium is a binary compound, containing the elements sulphur and potassium. Cyanide of ethyl is a binary compound containing the radicals cyanogen and ethyl. Sulphide of ethyl is a binary body containing an element and a compound radical. With regard to the constitution of these bodies all chemists are agreed. Their views respecting the constitution of the oxy-salts are less unanimous. Sulphate of potash, for instance, has usually been considered to be composed of the binary body potash united with the binary compound sulphuric acid, and therefore to belong to another class of substances—ternary. The binary theorists, however, would consider sulphate of potash to be a binary compound also, containing the simple radical potassium and the compound radical sulphion; i. e. anhydrous sulphuric acid plus one atom of oxygen—

K, SO, not KO, SO₂;

and so in regard to other oxy-salts. Both hypotheses can be supported by numerous facts and arguments.

Binate (Lat. bis, and natus, *born*). Growing in pairs; when two bodies of the same nature spring from the same point, as often happens in the segments of leaves.

Bind. A technical name in some parts of the country for the shales alternating with the coal in the coal measures. Such rocks are generally more or less calcareous, and alternate with sandstones and bands of ironstone nodules; they not unfrequently contain concretions of carbonate of lime and iron. [SHALE.]

Bind. In Music, a ligature or tie for the purpose of grouping notes together.

Binder. The name generally given to a beam intended to tie, or bind, together any building. It is applied commonly to the principal piece of timber in a double floor, in which it performs the part of a girder to carry the intermediate parts of the bearing of the ceiling and of the floor joists.

Binding Coal. [CLOSE-BURNING COAL and CAKING COAL.]

Binervate (Lat. bis, and nervus, *a nerve*). In Entomology, when the wing of an insect is supported by only two nerves.

Binnacle or Bittacle. In Navigation, the case or stand in which the steering compass is placed. It is fixed near the tiller or wheel. At night the compass is illuminated by a lamp placed over it.

Like many other sea terms, the word is of

BIOGENESIS

very doubtful origin. The form *binnacle* seems to indicate that the word is a corruption from Binnacle [which see]; while the form *bittacle* has led Mr. Wedgwood to connect it with the French *habittacle*, from the Low Latin *habita-culum*, as meaning a place for the steersman and the pilot. [BARNACLES.]

Bianite. A mineral found in the Dolomite of the Binnien Valley, in the Valais. It occurs in right rhombic prisms which are longitudinally striated and of a colour varying from steel-grey to black.

Binocle or Binocular Telescope (Lat. binus, *double*, and oculus, *the eye*). A telescope to which both eyes may be applied at once, and in which, consequently, an object may be observed with both eyes at the same time.

Binocular Perspective. [PERSPECTIVE.]

Binomial (Lat. bis, and Gr. *vōmos*, *law*). In Algebra, signifies a quantity composed of two terms, connected together by the signs + or -; thus, $a + b$ and $c - b$ are binomial quantities.

Binomial Equation. An equation which consists of two terms, and is, therefore, reducible to the form $x^n = A$ or $x^n - A = 0$. It has, of course, n roots, all of which are unequal. If a be any one of them, then, putting $x = ay$, the equation is reduced to $y^n - 1 = 0$; so that the n roots in question may be found by multiplying any one of them by the several n^{th} roots of unity. [ROOTS OF UNITY.]

Binomial Theorem. A formula, discovered by Newton, for expressing any power of a binomial quantity. It is usually written thus—

$$(1+x)^n = 1 + nx + \frac{n(n-1)}{1.2} x^2 + \frac{n(n-1)(n-2)}{1.2.3} x^3 + \&c.$$

from which four terms the law of the whole series will be sufficiently apparent. The method of obtaining the formula and of proving its validity for all values of n , will be found in any good algebra. When n is a positive integer the series is finite, and consists of $n + 1$ terms; in all other cases it is infinite, but convergent whenever x is numerically less than 1, no matter what n may be. It would be useless to attempt to describe the applications of this formula in mathematics: it is beyond question the most important one of elementary algebra.

Binormal (Lat. bis, and norma, *a rule*). A term employed by Saint-Venant (*Jour. de l'École Polytechnique*, cah. 30) to denote the line through a point of a non-plane curve which is perpendicular to two consecutive elements. It lies of course in the normal plane and is perpendicular to the osculating plane. The locus of binormals to a given curve is a skew surface the generators of which are cut orthogonally by the curve.

Biocellate (Lat. bis, and ocellus, *an eyelet*). In Entomology, when an insect's wing is marked with two eyelike spots.

Biogenesis (Gr. *bios*, *life*, and *gēnesis*, *birth*). A word used by Zoologists to define

BIOGRAPHY

the science which speculates upon the mode by which new species have been introduced on this planet.

Biography (Gr. *bios*, and *γραφω*, I write). The history of the life of an individual. Biography, in the progress of literature, appears to be nearly coeval with history itself. It has been ingeniously described as 'history teaching by example;' and this mode of instruction was perhaps peculiarly appropriate to early and simple times, in which the relative importance of individual men to the society in which they lived was greater than it can ordinarily be in periods of more advanced civilisation. But, although we have notices of many biographical writers among the classical authors of Greece, none of their works have been preserved to us (if we except the short narrative of the exploits of Agesilaus by Xenophon, for his celebrated *Memorabilia* of Socrates are rather in the form of a collection of sayings and anecdotes than a memoir) of earlier date than the Roman Empire. It is to a comparatively late age that we owe all the more interesting works of this description, some of which are among the most popular relics of the classical ages—the *Lives of Illustrious Men*, by Plutarch and Cornelius Nepos; the *Lives of the Cæsars*, by Suetonius, a work of which the details are strictly biographical; and the *Lives of the Philosophers*, by Diogenes Laertius. Biography may be said in strictness to differ from history not merely in the extent of the subject, but also, and perhaps more characteristically, in the mode in which that subject is treated. Thus, in classical literature, the works of Quintus Curtius and Arrian, although devoted exclusively to the actions of a single individual (Alexander), are not usually termed biographies; not only because the individual in question was the leader and foremost character in a course of great public events, but also because those public events form the subject-matter of their works, and not the more peculiar details of the personal life of their heroes. They are therefore more accurately denominated histories than biographies. On the other hand, the *Lives of the Twelve Cæsars* by Suetonius form, as has been said, a series of biographies, although the persons who furnish the subject were, like Alexander, arbiters of the destinies of a great part of mankind; because the details which they contain are chiefly of a private and personal nature. It is the object of history, among its other lessons, to make us acquainted with the influence which the actions, the characters, and the thoughts of individual men have produced on the course of events affecting society in general: conversely, it appears to be the province of the biographer to detail the effects which have been produced by external occurrences and circumstances on the character and conduct of individuals.

The best biographical dictionaries, though very imperfect, are the two French publications, *Biographie Universelle*, commenced in 1811 and continued by supplements; and the *New Bi-*

BIQUADRATIC EQUATION

Biographie Universelle, commenced 1853 and still in progress. English literature has nothing whatever to show in this branch, except the old *Biographia Britannica* (of Kippis) and Chalmers' *Dictionary*, commenced 1812, almost confined to literary notices of England, and extremely defective as to these.

Biotine. The name given by Monticelli to the Anorthite which occurs among the old lavas at Vesuvius. It is transparent, of a whitish or yellowish colour, and is distinguished from the other minerals with which it is associated by superior brilliancy. Named after the French chemist Biot.

Biotite. Uniaxial or Magnesian Mica. It occurs in six-sided tabular prisms, which have a perfect basal cleavage and are sometimes colourless, but generally dark green or brown, or nearly black. It has a vitreous lustre, varies from transparent to opaque, is sectile, and flexible, and elastic when reduced to thin laminae. It occurs in Skye, and at Inverness in Scotland; also at Vesuvius. Named after Professor Biot, who first pointed out the optical differences between the different kinds of Mica. [MEROXENE.]

Bipectinate (Lat. *bis*, and *pecten*, a comb). When a part has two margins toothed like a comb.

Bipeltate (Lat. *bis*, and *pelta*, a buckler). When an animal or part has a defence like a double shield.

Bipupillate (Lat. *bis*, and *pupilla*, the pupil of the eye). In Entomology, when an eye-like spot on the wing of a butterfly has two dots or pupils within it of a different colour.

Biquadratic. In Algebra, denotes the power immediately succeeding the cube; that is, the square of the square, or fourth power.

Biquadratic Equation. An equation of the fourth degree; that is to say, an equation wherein the fourth, but no higher, power of the unknown quantity appears. Its general form is—

$$x^4 + px^3 + qx^2 + rx + s = 0;$$

and its solution, as was first shown by Ferrari, may be made to depend upon that of the cubic equation

$$y^3 - qy^2 + (pr - 4s)y - s(p^3 - 4q) - r^2 = 0,$$

which is termed its *resolvent*. In fact, *y* being any root of this equation, those of the original will be the roots of the following two quadratics

$$x^2 + \left(\frac{p}{2} \pm \sqrt{\frac{p^2}{4} - q + y}\right)x +$$

$$\left[\frac{y}{2} \pm \frac{py - r^2}{4\sqrt{\frac{p^2}{4} - q + y}}\right];$$

where first the upper and then the lower signs are to be taken together. To verify this statement, it is merely necessary to multiply together the two last quadratic expressions; it will be found that their product, in virtue of the solvent, reduces itself to the original quartic. Other solutions have been given by Descartes,

BICQUATERNION

Waring, Simpson, Euler, Lagrange, and others, for a complete account of which, as well as for a full discussion of the problem, see Todhunter, *Theory of Equations*; Serret, *Algèbre Supérieure*, &c.

Biquaternion. [QUATERNION.]

Biradial (Lat. bis, and radius, *ty*).

When a part has two rays.

Birch (A.-Sax. *birc*). A hardy tree inhabiting the north of Europe, Asia, and America. The Common Birch (*Betula alba*) is valuable for its capability of resisting extremes of both heat and cold; its timber is chiefly employed for fire-wood; and its bark is extremely durable. The empyreumatic oil of the birch is used in preparing Russian leather, to which it gives its peculiar odour. The American Birch (*B. lenta*) produces a hard heavy timber, much used by cabinet-makers. The bark of the Paper Birch (*B. papyracea*) is employed by the North American Indians for a variety of useful purposes among others to form canoes. The bark of the Black Birch (*B. nigra*) yields a resinous substance known as Birch Camphor.

Bird of Paradise. A name originally applied to the species *Paradisæa apoda*, Linn., of which the skins, deprived of the wings, the feet, and the tail, have long formed a high-priced article of export from the eastern parts of the world. The value of these mutilated specimens of natural history arises chiefly from the extraordinary development and light and beautiful structure of the plumes which grow from the scapular and lateral regions of the body; and these plumes, combined with the velvety texture and brilliant metallic reflections of the ordinary feathers, especially those covering the head, render skins of the *Paradisæa* ornaments highly esteemed by the fair inhabitants of the most civilised countries. The remarkable plumage and the constant absence of the ordinary organs of locomotion in the imported specimens, easily gave rise to strange speculations as to the nature of this rare bird of the East; and the older naturalists delighted to describe it as destitute of feet, dwelling constantly in the air, wafted about in the bright beams of the sun independently of the ordinary mechanism of wings, and nourished with dew and the nectar and even odour of flowers. To beings thus imagined to be raised above the dull earth, and to enjoy ethereal food and a perpetual habitation in the air, no name could be more appropriate than Birds of Paradise or Heaven. The march of enquiry has, however, dispelled the fancied attributes and false charms of these lovely beings, and has restored to them their wings and feet. The latter, indeed, are remarkable for their robustness: they have three toes in front and one behind, as in other *Passeres* of Cuvier, with the middle toe shorter than the tarsus, the outer toe united to it at its base, and the inner one joined to it for half the length of the first phalanx. The form of the beak corresponds with that which characterises the tribe *Coraciiformes* of Cuvier; and their true food, which consists not only of the pulpy and

BIRTH, EVIDENCE OF

farinaceous parts of fruit, but also of worms, insects, the eggs and young of smaller birds, and even carrion, causes them to be ranked with the family of *Omnivores*, Cuv. In fact, they closely resemble in their habits our magpies and jays. The principal species of the genus *Paradisæa* are the Great or Common Bird of Paradise (*Par. apoda* of Linnæus); the Royal Bird of Paradise (*Par. regia*); the Red Bird of Paradise (*Par. rubra*); the Magnificent Bird of Paradise (*Par. magnifica*); the Six-threaded Bird of Paradise (*Par. sexsetacea*), which is characterised by three long and thread-like feathers, which grow from each side of the body; the Superb Bird of Paradise (*Par. superba*), which is smaller than the preceding, but perhaps the most beautiful of the genus; the Small Bird of Paradise (*Par. minor*), which measures about nine inches from the point of the bill to the end of the tail; and, lastly, the White Bird of Paradise (*Par. alba*).

Bird Pepper. A small shrubby *Capsicum* (*C. baccatum*), which is one of the species that afford Cayenne pepper.

Bird's Mouth. In Architecture, an interior angle, or notch, cut across the grain at the extremity of a piece of timber for its reception on the edge of another piece; as a rafter, for instance, upon a pole plate. *Bird's mouth* signifies also the internal angle of a polygon, its external angle being called a *bull's nose*.

Bird's-eye View. In the Fine Arts, a term used to denote a view arranged according to the laws of perspective, in which the point of sight, or the situation of the eye, is placed at a considerable height above the object viewed and delineated. In architectural representations it is used chiefly for the purpose of representing the disposition of the different courts, or quadrangles, or roofs of a building. It is a useful method of representing battles, as also of conveying a general notion of a small district of a country. [PERSPECTIVE.]

Birds. In Heraldry, are said to be rising, displayed, close, volant, &c. according to the different postures in which they are represented. Birds of prey, and cocks, when beaked and legged of a different tincture from the body, are said to be *armed* of that tincture.

BIRDS. In Zoology. [AVES.]

Birdlime. A glutinous substance extracted by boiling the bark of the holly tree; a similar substance may be obtained from mistletoe, from the young shoots of elder, and some other plants.

Birth, Evidence of. By the French *Code Civil* it is required that a declaration shall be made of every birth to the proper officer, within three days, with production of the child. The 'act of birth,' setting forth the time and place of the event, sex, and name of the child, and description of the father, is then immediately drawn up in the presence of two witnesses. It is entered on the register, and a copy kept by the parent. (*Code Civil*, art. 55.) In England by the 70th canon, and statutes of 1 & 7 Wm. III. and 4 Geo. IV. c. 76, the minister of every parish is required to keep a

BIRTH OF A SHIP

register of births. But now, by the Act for registering births, deaths, and marriages, 6 & 7 Wm. IV. c. 86, it is enacted that the parent, or occupier of a house in which a child is born, *may*, within 42 days after the birth, give notice to the district registrar; and *shall* give such information on being requested by the district registrar within the same time. After 42 days, the birth may be registered only in presence of the superintendent registrar, and on a peculiar declaration. After six months, registration of a birth cannot take place. Certified registers of births, as well as deaths, are to be forwarded after a certain time to the superintendent registrar, and copies of such registers to the general register office. (Secs. 19, 21, 22, 23, 33, 34.)

Birth, or Berth, of a Ship. The ground or space in which a ship is anchored, and which is said to be a *good birth*, or a *bad birth*; also, an apartment, as the midshipman's birth; also the space allotted to a seaman to sleep or hang his hammock in.

Bis (Lat. *twice*). In Music, a word placed over passages which have dots postfixed to one bar, and prefixed to a subsequent bar, signifying that the passage between the dots is to be played twice over.

Biscuit (Fr. *twice cooked*, like the German *zwieback*, *twice baked*). In Sculpture, a species of porcelain, of which groups and figures in miniature are formed, which are twice passed through the furnace or oven. It is executed without glaze upon it. In Pottery, this term is applied to earthenware and porcelain, after it has been hardened in the fire, and before it receives the glaze: in this state it is permeable to water.

Bristous (Lat. *bis*, and *seta*, a *bristle*). In Zoology, when an animal or part is furnished with two bristle-like appendages.

Bisexual (of two sexes). Is a term applied to flowers which contain both stamens and pistil within the same envelope: it is the same as the word *hermaphrodite* in botany.

Bishop (Gr. *ἐπίσκοπος*, Lat. *episcopus*, an *overseer*). In all denominations of Christians which admit the episcopal form of government, the bishop is the superior of the three orders, standing in rank and office distinct from the presbyter or priest. [EPISCOPACY.] This distinct office consists in the power of ordination, confirmation, and consecration, none of which ceremonies may be performed by an inferior clergyman. The clergy of a diocese are subjected also to the ecclesiastical authority of their bishop, who alone institutes to benefices, licenses curates, and has considerable discretionary power in requiring the residence of his clergy on their cures, and in superintending the discharge of their duties in them.

The mode of appointment to bishoprics varies in different establishments. In early times the bishop was generally elected by his clergy and laity. After the establishment of Christianity, the Eastern emperors assumed the right of nominating to some of the prin-

BISMUTHINE

cipal sees, and exercised great influence over the elections generally. In the West of Europe the kings of the barbarians, after the conversion of their subjects, arrogated to themselves similar authority, which was jealously counteracted by the see of Rome. In the middle ages the pope assumed in most cases the absolute nomination, which claim has been given up in later times in many Catholic countries, where the king or clergy recommend and the pope only ratifies the appointment. In England the appointment is virtually in the hands of the sovereign, who upon the demise of the bishop receives from the dean and chapter intimation of the event, with a request for permission to supply the vacancy. The king accords his permission to that effect, and at the same time recommends a person to their choice—a recommendation which is equivalent to a command, as it cannot be waived without incurring the severe penalties of a *præmunire*.

Bismuth. A brittle yellowish-white metal, of a crystalline texture. Its specific gravity is 9·8; it fuses at 507°, and at a red heat it sublimates in close vessels. It conducts heat less perfectly than most of the other metals. When strongly heated it burns with a bluish-white flame, and is rapidly oxidised. Its equivalent upon the hydrogen scale is 213; and it forms only one salifiable oxide, which is a ter-oxide, = BiO_3 . When nitrate of bismuth is dropped into water a white powder is thrown down, formerly called *magistery of bismuth* or *pearl white*: it is a subnitrate. A brown peroxide of bismuth, = BiO_2 , is obtained by fusing the ter-oxide with caustic potash. Some of the alloys of bismuth are remarkable for their fusibility: a compound of 8 parts of bismuth, 5 of lead, and 3 of tin, melts in boiling water, and is commonly called *fusible metal*. The ores of bismuth are not common; but it occurs *native*, and combined with oxygen, sulphur, and arsenic. The Germans call it *wismuth*.

Bismuth Lead-ore. [NIXEDLE ORE.]

Bismuth Nickel. [GRÜNAUTITE; SAYNITE.]

Bismuth Ochre. A dull earthy mineral of a yellowish or ash-grey colour, sometimes verging on apple-green, which is found in Cornwall at the Royal iron mine near Lostwithiel, and in small quantities in the parish of St. Roach at Cost-all-Joet Mine. It consists according to Lampadius of oxide of bismuth 86·4, oxide of iron 5·1, carbonic acid 4·1, water 3·4.

Bismuthine. Tersulphide of bismuth, composed of 81·6 per cent. of bismuth, and 18·4 sulphur. It occurs in lodes and beds in the older rocks, together with ores of arsenic, copper, iron, lead, &c.; either crystallised in acicular (often minute) prisms, or massive with a foliated structure like that of Galena, or fibrous like Antimony. The colour and streak are tin-white or lead-grey, sometimes yellowish-white, with an iridescent tarnish; lustre metallic; opaque, soft and brittle; fuses in the flame of a candle.

BITTER SPAR

Bismuthine is found in Cornwall and in Cumberland. The principal foreign localities are Siberia, Norway, Sweden, Saxony, Bohemia, &c.

Bismuthite. Native carbonate of bismuth, composed of 80.28 per cent. of oxide of bismuth, 6.29 carbonic acid, and 3.43 water. It occurs in pseudomorphous acicular crystals after Bismuthine, in Saxony at Johannegeorgenstadt, Ullersreuth, and Aue; also after Native Bismuth at Schneeberg. The Bismuth-glance of the gold-mines at Chesterfield, South Carolina, consists of hydrated carbonate of bismuth, with small quantities of earthy admixtures.

Bison (Gr.). A genus of Bovidae, found in both the Old and New Worlds. The aurochs (*B. Bonassus*) with 14 ribs, and the American bison (*B. Americanus*), form the typical examples of the genus. In India and the Sunda Isles the Gayal (*B. frontalis*), the Gour (*B. Gaurus*), and the Banting (*B. Banting*) are found, and have been erroneously considered to be the source of our domestic oxen, from which they are clearly distinguished by the number of ribs (13 in *Bos*). The Yak (*B. poëphagus*) is found in Thibet, and is the species from which the so-called horsetails denoting rank in the East, are derived. Three species of Bison are known to palaeontologists, one of which (*B. prisceus*) coexisted with the gigantic true oxen and buffaloes of the Pliocene period.

Bispinosus (Lat. bis, and spina, a spine). When an animal or part is armed with two spines.

Bissextile (Lat. bis, twice, and sextilis, sixth). The name given to the year which contains 366 days. The calendar used in all European countries is founded on that of the Romans, as reformed by Julius Cæsar. In the calendar of Cæsar the length of the year was fixed at 365½ days; and in order that the year should always begin with the beginning of a day, it was directed that every fourth year should contain 366 days, the other years having each 365. The additional day, which thus occurred every fourth year, was given to February, the shortest month, and was inserted in the calendar between the 24th and 25th days. In the peculiar method of reckoning the days of the month adopted by the Romans, namely, of reckoning backwards from the 1st of the succeeding month, it would have been very inconvenient to interrupt the order of numeration; accordingly the 24th, which was called *sexto Calendas Martii*, was reckoned twice, and the supernumerary or repeated day called *bis sexto Calendas*. Hence the term *bissextile*. In English, *leap year* has the same signification.

In the Julian calendar every year was bissextile; but this supposes the year to be 365½ days, which errs in excess by 11 minutes 10.35 seconds. Accordingly, in the course of a few centuries, the error will amount to days, and cause the commencement of the year to change its place with respect to the seasons. When the Julian calendar was introduced, the equi-

nox fell on the 25th of March; in 1582, when the calendar was reformed by Pope Gregory XIII., it had fallen back to the 11th; and as it was then supposed that the error of the Julian calendar amounted to three days in 400 years, it was ordered that the intercalary day should be omitted in all the years which terminate centuries, excepting those which are multiples of 400. The Gregorian rule of intercalation is therefore as follows: Every year of which the number is divisible by 4 is a leap year; excepting the centesimal years, which are only leap years when divisible by 4 after suppressing the two zeros. Thus 1600 was a leap year; but 1700, 1800, and 1900, which would be bissextile in the Julian calendar, are common years in the Gregorian.

This regulation, though it would for a long time preserve the commencement of the year at the same place in the seasons, is not yet quite correct. It supposes the length of the year to be 365 days 5 h. 48 m. 12 seconds, which is too great by 22.38 seconds; an error which amounts to a day in 3,866 years. As this number 3,866 approaches to 4,000, it was proposed by Delambre to correct the Gregorian rule by making the year 4000 and all its multiples common years. Should our present calendar continue to be in use 2,000 years hence, posterity may then begin to consider whether they will adopt this suggestion. [CALENDAR.]

Bistort (Lat. bis, and tortus, twisted). The root of the *Polygonum Bistorta*, an indigenous plant; it is used in medicine as a powerful astringent.

Bistre. In Painting, a dark brown colour, made from the soot of dry wood, for which purpose that of dry beech is preferable.

Bisulcate (Lat. bis, twice, and sulcus, a furrow). In Mammalogy, a term signifying a foot resting upon two hoofed digits.

Bit (A.-Sax. bitol). That part of the bridle which goes into the mouth of a horse.

Bit. A general name for the metal part of several tools used for boring, and made so as to fit at the upper end in the handle of a socket; they are applied for boring large holes in hard wood, and in all cases where accuracy is required. The bit of a key is the part fitted to the shank in which the wards are cut; this is called a blank until the wards are so cut. The term is also used for the hammer used by masons for rough picking, or dressing granite.

Bitacle. [BINNACLE; BINOCLE.]

Bitter Apple. The fruit of the *Citrullus* or *Cucumis Colocynthis*.

Bitter Principle. This term has been applied to certain bitter products of the action of nitric acid upon animal and vegetable matters. [CARBAZOTIC ACID.]

Bitter Salt. Sulphate of Magnesia, or Epsom Salt.

Bitter Spar. A Mineralogical term, generally applied to certain crystallised or large-grained and easily cleavable varieties of *Dolomite*, or double carbonates of lime and magnesia. It usually occurs in obtuse rhombohedrons,

BITTERN

nearly allied to carbonate of lime, and consists of about 66 per cent. of carbonate of lime, and 45 of carbonate of magnesia, the latter being sometimes replaced by small quantities of iron and manganese. It is a common mineral in many English localities, but the finest and most transparent crystals are found at Travassella in Piedmont, at St. Gothard, and near Gap in France. [BROWN SPAR; PEARL SPAR TALC SPAR; DOLOMITE.]

Bittern. [ARDEA.]

BITTERN. The residue of sea water after the common salt has been separated by evaporation. It contains *muriate of magnesia*, which gives it a bitter taste.

Bitts. In Navigation, strong pieces of wood firmly fixed on the deck round each mast for the purpose of leading and securing ropes. Cable bitts are stronger and heavier, being encased in iron, and used to check or ease the cable when going out.

Bitumen (Lat.; probably from Gr. *βίτς*, the pitch tree, because it resembles pitch). A name under which are included several distinct varieties of inflammable mineral substances, which, like pitch, burn with flame in the open air. [ASPHALT; ELASTIC BITUMEN; MALTHA or MINERAL TAR; PETROLEUM.]

Bituminous Coal. The term commonly applied to coals which burn with a smoky flame, and occupy a place between Lignite on the one hand, and Anthracite on the other.

Bituminous Shale. In many coal fields in various parts of the world there are numerous bands of tough clayey matter of a grey, brown or black colour, sometimes passing into coal, and resembling bad coal in appearance. They have more or less of a slaty fracture, are often repeated, like other beds of clay, in vast thickness of strata, and occupy a definite position with regard to coal. They are found generally, but not always, near true coal of all ages. The *posidonia schists* of the lias, and the *paper coal*, so called, of the tertiary period, near Bonn, are varieties.

Although some of these shales yield much gas on exposure to destructive distillation [Gas], they are even more valuable as affording oils and paraffine, when distilled at a dull red heat.

The percentage of oil obtained from bituminous shales varies exceedingly, but less than five per cent. can hardly be remunerative. Some of these, which afford as much as thirty per cent., are extremely valuable, such as the so-called *Boghead coal*, or *Torbane mineral* of Scotland. [PARAFFINE.] Shales approach coal in their appearance, and are used for burning.

Bituminous Wood. [LIGNITE.]

Biuret. One of the products of the action of heat upon urea. It occurs in granular crystals, and is intimately related to bicyanate of ammonia.

Bivalves (Lat. *bis*, and *valva*, a valve). A term commonly applied to the Lamellibranchiate Aerophalous Molluscs, on account of the structure of their shell, which consists of two

BLACK GARNET

parts or valves, joined together by an elastic ligament at the *cardo* or hinge. The testaceous covering of the Palliobranchiata is also composed of two valves or shelly pieces; but these are never joined by elastic ligament.

Bivouac (Fr., from Ger. *beiwache*, by-watch: Latham). A term in the Military art, employed to denote the system by which soldiers on a march, or in expectation of an engagement, remain all night in the open air, in contradistinction to the systems of encampment and cantonment.

Bixaceæ (from *Bixa*, one of the genera). Another name for the *Flacourtiaceæ*, an order of Hypogynous Exogens, containing the genus *Bixa*, one of whose species, *B. Orellana*, produces the substance called *annatto*, used for colouring cheese. The species are all trees or shrubs inhabiting the tropics.

Bixin. The colouring principle of annatto.

Black Amber. The name given to Pitch-coal by the amber diggers of Prussia, who manufacture it into various ornamental articles.

Black Ash. Impure carbonate of soda.

Black Band. A variety of Clay-ironstone or compact carbonate of iron, often containing as much as from 25 to 30 per cent. of carbonaceous matter. It occurs largely in the coal-fields of North Staffordshire and Scotland, and is the ore almost exclusively used in the latter country for the production of iron. Strata of Black Band are also found abundantly in beds between the coal-seams of the Westphalian Coal-measures on the Ruhr, in the Coal-measures on the Worm (district of Aachen), and in those on the Inde.

Black Cap. This term is generally applied to a species of frugivorous warbler (*Curruca atricapilla* of Brisson); but it is also occasionally given to the great titmouse (*Parus fringillago*), the marsh titmouse (*Parus palustris*), the black-headed bunting (*Emberiza schenckius*), the stonechat (*Luscinia rubicola*), and even to the black-headed gull.

Black Chalk. A kind of black clay, containing a large quantity of carbon, found in Caernarvonshire and the Isle of Isla; also in France, Portugal, Spain and Italy. The finer sorts are made into artists' crayons, and used for drawing on paper.

Black Coal. One of the three species into which Coal was divided by Jannson. It comprises Slate Coal, Cannel Coal, Foliated Coal, &c.

Black Cock. The name of a native species of grouse. [TETRAO.]

Black Copper. An earthy oxide of copper, resulting from the decomposition of other ores. [MELANITE.]

Black Drop. A preparation of opium, known also under the name of *Lancaster*, or *Quakers' black drops*. It is said to be a solution of opium in verjuice.

Black Flux. A mixture of carbonate of potash and charcoal, obtained by dehydrating tartar with half its weight of nitre.

Black Garnet. [MELANITE.]

BLACK HÆMATITE

Black Hæmatite. [PSILOBLANR.]

Black Jack. The name usually given by Cornish miners to Blende or sulphide of zinc. In some localities the occurrence of this ore is looked upon by the miners as a favourable indication, and there is a common saying that '*Black Jack rides a good horse*;' in other districts, on the contrary, Black Jack is said to '*cut out the ore*.'

Black Lead. A name commonly, but improperly, applied to Plumbago or Graphite, in consequence of the mark it leaves when drawn across paper, like that produced by lead.

Black Letter. Is the name now applied to the old English or modern Gothic letter, which was introduced into England about the middle of the fourteenth century, and became the character generally used in MS. works before the art of printing was publicly practised in Europe. On the application of that art to the multiplication of books, about the middle of the fifteenth century, the block books, and subsequently those printed with movable types, were in this character, in imitation of writing. The first printed Bible, known as 'the Mentz Bible,' or 'the Mazarine Bible,' without date, a copy of which was found about the middle of the last century in the library of Cardinal Mazarin, in Paris, was an instance of this. Books printed before the year 1600 are generally in this character, and are styled black-letter books. (Hallam, *Literature of Europe*, vol. i. pt. i. chap. iii.)

Black Manganese. [HAUSMANNITE.]

Black Sea. This great inland sea, together with the Sea of Marmora, which connects it with the Mediterranean and the Sea of Azof, from which the Crimean peninsula only partly separates it, has an area of nearly 200,000 square miles, and is in an important geographical sense subordinate to the Mediterranean. It also serves to connect the Mediterranean with the Caspian; for the waters of the Don which enter the Sea of Azof, are only separated by a narrow tract of low land from those of the Volga, which enters the Caspian. A small difference in the level of the steppes of Astrakan would at once carry the waters of the Atlantic into the plains of Siberia.

The waters of the Black Sea are much less salt than those of the adjoining larger sea, owing to the quantity of fresh water constantly pouring into them. Another result of this rush of fresh water is, that a current sets round the western shore into the Mediterranean.

The Black Sea is considered to be deep compared with the adjacent seas. It must, however, be in course of silting up.

The mountains of the Caucasus form part of the north-eastern boundary of the Black Sea, and extend into the south of the Crimea. Sudden and severe storms, probably connected with the surrounding mountain-land, are common in the Black Sea during the winter season.

Black Tin. The name applied by miners to tin ore ready for the smelter.

BLASPHEMY

Black Wadd. An ore of manganese. [WAD.]

Black Wash. A lotion composed of calomel and limewater.

Black-bird. [TURNUS.]

Blakelite. Octahedral crystals of iron-alum (Coquimbite) from Coquimbo, named after Mr. J. H. Blake, by whom they have been analysed.

Blanching. In Gardening, is the whitening of the stems, stalks, or leaves of plants by tying them together, or by earthing them up, so as to exclude the light. Its object is generally to diminish the intensity of their native properties, and to render them more crisp and agreeable to the palate.

Blank Cartridge. A cartridge with powder only, used for saluting and drill.

Blank Verse. In some modern languages, the heroic verse of five feet without rhymes. Blank verse is peculiar to the Italian, English, and German languages; having been imported into the two latter from the first. In Italian the line is of eleven syllables; and is used invariably in the drama, and frequently in serious poetry, epic or didactic. In English it was also first adopted by the dramatists, and transferred to epic poetry by Milton. The Miltonic verse is constructed with closer attention to the melody of the cadence and cæsura than the dramatic: it admits also less frequently of the eleventh syllable, which in English poetry must be regarded as a sort of license; while Shakspeare and other dramatists, occasionally double the short syllable at the end, and thus extend the number to twelve.

Blaps. A Fabrician genus of Coleopterous insects, now the type of a family (*Blapsidæ*), characterised by the absence of wings; maxillary palpi terminated by a large hatchet-shaped joint; body oblong and oval. All the species are of a dark or black colour, and have the elytra soldered together, and bent down at the sides of the abdomen so as to embrace that part. There are three British species of the genus *Blaps* proper, which are known by the trivial names of 'darkling' or 'church-yard beetles,' and are regarded by the vulgar of this and other countries as insects of evil omen.

Blas. A term applied by Van Helmont to certain supposed emanations of the heavenly bodies.

Blasphemy (Gr. *Βλασφημία*). According to its supposed etymology, this word signifies the offence of using injurious language, as calumny, reviling, &c.; and in this sense it is used in the New Testament; the word 'railings,' in 1 Tim. vi. 4, being in the original 'blasphemies.' But in the modern and restricted sense, 'blasphemy' signifies the use of insulting, or derogatory, or unbelieving language, with respect to God and divine things. Under this meaning it has been considered a civil crime in most Christian countries, in imitation of the practice which prevailed among the Jews. (Lev. xxix.) In England, by common law, it was punishable with fine, imprisonment, and other corporal punishment. By 9 Wm. III. c. 32, it was first

BLAST

made a statutable offence, and extended so as to comprehend even the mere denial of some fundamental doctrines of Christianity; and rendered subject to very severe inflictions. Unitarians were relieved from the penalties of this Act by 53 Geo. III. c. 160. But it is almost obsolete in practice with respect to other offenders.

Blast (A.-Sax. *blast*). A term used in Metallurgy to express the current of air forced into furnaces by bellows, or air engines, for the purpose of reducing the ores to a merchantable form. There are two kinds of blast in use in the iron manufacture, the hot and the cold blast. The hot blast is obtained by forcing the air through a series of hot pipes, and its effect is to facilitate the fusion of the metal, at the same time that the quality of the latter is deteriorated; the cold blast requires a greater quantity of fuel to reduce the same quantity of ore, and it yields a firmer and more even quality of metal than the hot blast.

Blast Furnace. A furnace fed with air by one or more pairs of bellows or blowing machines. In large iron furnaces the blast is frequently heated before reaching the fuel. [HOT BLAST.]

Blastema (Gr.). In Anatomy, the homogeneous gelatinous and granular basis of the ovum, in which the organic elements characteristic of the different tissues are deposited in the early stages of development.

BLASTEMA. In Botany, the axis of growth of an embryo: that is to say, the plumule, the radicle, and the part which connects them, the cotyledons being removed.

Blasting. [MINING.]

Blastocarpous (Gr. *βλαστός*, a germ, and *καρπός*, fruit). That kind of fruit which germinates inside the pericarp, as the mangrove.

Blastoderm (Gr. *βλαστός*, and *δέρμα*, skin). In Anatomy, the germinal skin or membrane, or that granular membrane or stratum which lies immediately beneath the membrana vitelli of the ovum, and which is the seat of development of all parts of the body of birds.

Blastus (Gr. *βλαστός*). A name sometimes given to the plumule and radicle of grasses.

Blatta (Lat.). A genus of nocturnal Orthopterous insects, commonly called cockroaches, or black beetles. In modern Entomology, it forms the type of a family, including many genera.

Blazonry. The art of deciphering coats of arms; also, that of expressing or describing a coat of arms in appropriate language. The word is supposed to be derived from the German *blasen*, to blow, and to have originated in the ceremonial of tournaments, from which so many other terms and usages in heraldry are derived; it having been customary on these solemn occasions for the herald to blow a trumpet when he called out the arms of a knight on ushering him into the lists. Blazonry requires a knowledge of, 1. The points of the shield, which are nine in number [POINTS]; 2. The field, that is, the tincture or tinctures forming

BLEACHING

the ground of the coat [TINCTURE]; 3. The charges, or devices borne on the field [CHARGE]; 4. The ordinaries [ORDINARY].

Bleaching (Ger. *bleichen*). This process consists in a series of operations, by which the natural colours of various substances are discharged, so as to whiten them. It is effected either by the action of various solvents, aided by exposure to light, air, and moisture, upon the bleaching ground; or by the aid of chlorine. Cotton is more easily bleached than linen, in consequence of its being originally whiter, and having a less powerful attraction for the colouring matter. In bleaching these goods upon the old principle, warm water is first liberally applied to remove the weaver's paste or dressing; they are then *bucked*, or boiled in a weak alkaline ley; and after having been well washed, are spread out upon the grass, so as to be freely exposed to the joint agencies of light, air, and moisture; the bucking and exposure are alternately repeated as often as necessary; the goods are then *soured*, that is, immersed in water slightly acidulated by sulphuric acid; lastly, they are very thoroughly washed and dried. By these operations the texture of the goods is to a certain extent impaired, and much time is required to complete the process, which also cannot be carried on in the winter months. But the exposure upon the bleaching ground is now to a great extent discontinued; and the same effect is obtained, after the process of bucking, by the action of weak solutions of *chlorine*, or of *chloride* of lime, which, if skilfully used, can scarcely be said to injure the goods more than the long-continued exposure. The theory of bleaching has not been satisfactorily developed; but, from such experiments as have been made in reference to it, it appears to be a process of oxidisement, and to depend upon some peculiar influence of *nascent* oxygen, or perhaps of ozone, upon the colouring matter.

The colour of manufactured wool depends partly upon its own oil, and partly upon the applications made to it in the loom. These are got rid of in the fulling mill by the joint action of fuller's earth and soap; the cloth is then well washed and dried, and is tolerably white. If the slight yellow tint which it retains is objectionable, it is improved by adding a little stone-blue to the washing water, or by exposure to the fumes of burning sulphur; this latter method, however, gives it a harsh feel, and if afterwards soaped its yellowishness returns.

The colour of raw silk depends upon a natural yellow varnish, which is got rid of by boiling it in white soap and water, and by repeated rinsings. Certain articles of wove cotton, such as stockings, are bleached as usual, and finished by the action of *sulphurous acid*, or the fumes of burning sulphur. Straw is also whitened by a similar operation; and hence bleached straw hats are apt to have a disagreeable sulphurous smell. A good account of bleaching will be found in Parkes' *Chemical Essays*.

BLEACHING POWDER

Bleaching Powder. Chloride of lime, made by exposing slaked lime to the action of chlorine. [CHLORINE.]

Blende. Antimonate of lead; probably a mechanical mixture of lead and antimony ores, produced by the decomposition of other ores of antimony. It occurs in Cornwall and in Siberia.

Blende (Ger. *blenden*, to *dazzle*; from its lustre). Native sulphide of zinc; composed, when pure, of 67 per cent. of zinc and 33 sulphur. It occurs crystallised in octahedrons and other allied forms. The colour passes from transparent yellow to opaque black. The lustre is resinous or glassy. The dark coloured kinds often contain sulphide of iron, and frequently 1 or 2 per cent. of sulphide of cadmium is present, especially in the red varieties, as in that of Marmato, near Popayan. [MARMATITE.] Blende is of common occurrence in lodes and metalliferous deposits, associated with most ores and sometimes constituting the matrix of the lode. It is found in large quantities in Cornwall [BLACK JACK], Cumberland, Derbyshire, and the Isle of Man; also in Spain, the Harz, Hungary, Transylvania, Saxony, Bohemia, Sweden, and in many parts of North America.

Blende, though a useful ore, is more difficult of reduction than Calamine: much of the zinc obtained from it is used for making brass.

Blennius (Gr. *βλέννα*, *mucus*). In Ichthyology, a genus of Acanthopterygian fishes, of the family of Gudgeons (*Gobioidæ*), remarkable for the quantity of mucus secreted from the skin, and for the viviparous generation of some of the species, of which the *Blennius Pholis*, a species common along the shores of Britain, is an example.

Blennorrhœa (Gr. *βλέννα*, *mucus*, and *ῥέω*, *I flow*). An inordinate discharge or secretion of mucus.

Blepharitis (Gr. *βλέφαρον*, *the eyelid*). Inflammation of the eyelids.

Bleu de Paris. A fine blue dye obtained by the action of bichloride of tin on aniline.

Blighia (named after Captain Bligh, of H.M.S. 'Bounty,' who in 1787 conveyed the bread-fruit and other trees to the West Indies from Tahiti). A genus of *Sapindaceæ*, the only species of which, *B. sapida*, is the Akee, an edible fruit of the West Indies and South America. The edible portion is the aril, a white spongy substance in which the seeds are partially embedded; and this, in tropical countries, is found to possess grateful subacid qualities. The Akee forms a small tree with pinnated leaves.

Blight (Old High Ger. *Blich-flur*, *blight-fire*; Wedgwood, Latham). A term in common use for supposed atmospheric injuries received by plants. Before effects were traced to their causes with the same care that they are at present, the sudden discolouration of the leaves of plants, their death, or their being covered with minute insects or small excrescences, was called by the general name of *blight*; and this *blight* was

BLOCK

attributed to some mysterious influence in the air, to the east wind, or to thunder, because these states of the atmosphere commonly accompanied these phenomena. It is now found that what is called *blight* is in some cases the effect of insects, to the progress of which the dry state of the atmosphere produced by east winds is peculiarly favourable; while in other cases it is caused by parasitical fungi. The appearance of these fungi on corn crops is frequently designated by farmers as the *fire blast*: while on peach and other trees in gardens it is called *mildew*.

The sudden death of plants without apparent cause, and also the withering and drying up of part of their leaves and branches, to which appearance the term *blight* should perhaps be restricted, are produced by the transpiration of water from the leaves taking place with greater rapidity than it can be supplied by the absorption of the roots, and also by the roots becoming attacked by fungous spawn. In very hot weather in summer, branches of fruit trees trained against walls, or of gooseberry bushes on espaliers, are sometimes withered up in a few minutes from this cause.

What countrymen call the *blight* on standard apple or other fruit trees in orchards is commonly nothing more than the injuries done to the leaves and buds by the caterpillars of certain moths; that on thorn hedges, by the caterpillar of the saw fly, or of the ermine, or of some other moths; and that on roses, by the aphides or green fly.

Blind Coal. A name given to Anthracite in some parts of Scotland.

Blind Story. A term sometimes used in mediæval architecture to express the triforium of a church, in contradistinction to the clerestory.

Blind Worm. An Ophidian or serpent-like reptile, which is the type of the genus *Cecilia* [see that word]. The term is also sometimes applied to the slow-worm. [ANGUIS.]

Blindage. In Fortification, a term applied to a shell-proof or splinter-proof roofing, constructed to cover magazines, batteries, &c.

Blindness. [VISION.]

Blinkers. Expansions of the sides of the bridle of a horse, to prevent him from seeing on either side, but at the same time not to obstruct his vision in front.

Blister-fly. [CANTHARIS.]

Blistered Copper-ore. The name applied in Cornwall to reniform and botryoidal Copper Pyrites. It is met with at Cook's Kitchen, Huol Bassot, and other mines.

Blistered Steel. [STEEL.]

Block (Fr. *bloc*). In Architecture, this term is applied to large unworked masses of marble or stone; it is also used to denote a nodillion in a cornice, or the small projections left on the stones of some buildings, which are supposed to have been indications of the unfinished state of the work, though they are discovered upon some elaborately finished buildings, such as the choragic monument of Thra-

BLOCK

syllus. The introduction of the blocks on the arch stones of the Pont du Gard is a striking illustration of their use.

Block. In Navigation, the case that contains the wheel or *sheave* of the pulley (which last term is not used at sea). Two or more blocks, with the rope, constitute a *tackle*. Blocks are also the pieces of wood and iron on which the ship's keel is supported when she is in dock.

Block Machinery. A system or assemblage of machines for manufacturing the shells and sheaves of blocks required for ship tackle. The term is specially applied to the ingenious machinery invented by the late Sir M. I. Brunel, and set up in the dockyard at Portsmouth between 1802 and 1808, and also at Chatham about 1807, for the supply of the Royal Navy. By these machines every operation connected with the construction of blocks, from the cutting up of the timber to the polishing of the iron pinion on which the sheave turns, is performed with astonishing celerity and precision; and when it is known that a single line-of-battle ship requires about 1,430 blocks for her equipment, the advantage and even the necessity of abridging the labour of construction by appropriate machinery will be understood. Although it would scarcely be possible, without entering into long details and the aid of drawings, to give any idea of the peculiar mechanism employed, the principal operations may be easily indicated. In the first place the rough timber (which is generally elm) is squared by an upright saw; it is then cross cut into pieces of the proper length by a circular saw. These pieces are then brought under the *boring machine*, when one centre bit bores a hole for the centre pin of the sheave, and another bores another hole at right angles to the former at one extremity of the mortise (or two or more such holes are bored when the block is to hold two or more sheaves) to admit the first stroke of the chisel. The next operation is performed by the *mortising machine*, which consists of a set of cutting chisels attached to a movable frame, and making from 100 to 130 perpendicular strokes in a minute, the block being placed on a carriage which at every ascent of the chisels advances forward a little until the proper length has been mortised out. The block is then removed from the mortising machine, and the four corners are taken off by a circular saw, after which it is placed under the *shaping machine*, when, by tens at a time, the proper curvature is given by means of a tool moving in a direction curved towards the line of the axis. Lastly, the *scoring machine* scoops out a groove round the longer diameter of the block to receive the hempen or iron strap which goes round the block, and by which it is suspended when in use, and the *shell* is thus completed. The *sheaves* of the block are made of lignum vitæ, of which a log is first cut into plates of the proper thickness by a circular saw. The plates are then carried to the *crown saw*, which at once bores the centre

BLOCKHOUSE

hole through which the pin is to pass, and gives an exact circular form. They are next brought to the *coaking machine*, for the purpose of having grooves cut in them, on both sides, for the insertion of the *coak* or bush, which is of gun metal and of a peculiar shape (to prevent them from turning in the sheaves), the section being bounded by three semicircles, the diameters of which form the sides of an equilateral triangle. This part of the machinery is exceedingly curious; and so accurately is the operation performed that the coaks are fixed in the sheaves by the tap of a hammer. The two coaks (one on each side of the sheave) are secured by copper rivets passing through them and the sheave—an operation also performed by the machine. The sheave is then completed by turning a groove round its periphery for the rope to run in, and by smoothing its sides, both operations being performed on the same lathe. The iron pin only now remains, and this is also turned and polished by engines for the purpose. The whole of the machinery is put in motion by straps passing over drum-heads, and is driven by a single steam engine of 32-horse power. It is found that by means of this machinery ten men can with ease finish in one year from 130,000 to 140,000 blocks of different sizes.

Block Plan. A plan of a ground or dwelling, representing its general arrangement without entering upon any of the details. It is customary to commence a series of plans by such a drawing, which is usually made upon a very small scale.

Block Tin. The tin which is sold in commerce under this name is less pure than the *grain tin*, being made from the common ore of the veins; the best qualities of this metal are the Banca, the Cornish, and the Spanish tin. The term is also applied to articles of inferior value, which are made of iron plate covered with a coating of tin, of variable thickness according to their qualities.

Blockade. In International Law, the right to blockade the ports of an enemy in war, and to exclude neutrals, is limited by the following recognised principles: 1. The blockade must be substantial, by means of a sufficient force to prevent the entry or exit of vessels; otherwise a neutral is not bound to respect it. 2. It is essential that the neutral should have notice of the blockade; otherwise his ship cannot be justly condemned. A counter notice should also be given by the blockading Power when the blockade has ceased. In England, a blockade is properly declared by the king in council.

Blockade. In Military art, signifies effectually confining the garrison within a fortress by a circle of fortified posts. The blockade of Pampeluna is a famous instance of this, and is well described in Sir John Jones's *Journals of Sieges*.

Blockhouse. A wooden building occupying the same position in a fieldwork that a tower does in a permanent fort.

BLOCKING COURSE

Blocking Course. Masonry or brickwork placed upon the top of a cornice, as the termination of a wall.

Blockship. Is a large vessel of war, employed on coast duty for the protection of a specified district. These ships are rarely fit for operations in the open sea.

Blond Metal. A peculiar kind of Coal-measure Clay-ironstone, which after being smelted is made into a variety of tools. It is found at Wednesbury in Staffordshire.

Blood (A.-Sax. blod). The fluid which circulates in the heart and blood-vessels. When viewed under the microscope it appears to consist of very minute *red globules* floating in a colourless fluid. The average quantity in an adult man is estimated at about 28 lbs. It is of two distinct colours in the arterial and venous systems; florid red approaching to scarlet in the former, and dark crimson in the latter. Its specific gravity is between 1.050 and 1.070. When drawn from its vessels it gelatinises or coagulates in the course of a few minutes at common temperature, and soon separates spontaneously into *serum* and *coagulum*. The serum is a yellowish soapy-feeling fluid, of the specific gravity of about 1.030. It exhibits a slight alkaline reaction upon test papers; when heated it becomes opaque, and at 156° it coagulates. It is also coagulated by alcohol, and by most of the acids; acetic acid and ether do not coagulate it; solutions of corrosive sublimate, of subacetate of lead, and of chloride of platinum occasion precipitates in it, even when considerably diluted with water. These properties of serum are dependent upon the presence of a peculiar proximate animal principle called *albumen*; the same substance, and with very nearly the same properties, constitutes the *white of egg*, the coagulability of which by heat is well known. Besides the above there is another most delicate test of albumen in solution, which consists in adding to the liquid suspected to contain it a little strong *acetic acid*, and afterwards a few drops of a solution of ferrocyanide of potassium. If albumen be present, a white cloud is produced. White of egg is coagulated by ether, while serum is not. According to Marec 1,000 parts of serum of human blood contain 900 of water, 87 of organic matter and 3 of saline matter.

The coagulum of the blood contains the colouring particles; and when carefully washed, these are carried out of it, and a tenacious whitish matter remains, which has been termed *fibrine*.

The colour of the blood depends upon the presence of small corpuscles, or flattened cells, containing a red colouring principle. In the mammalia, they are not spherical, hence the term *globule* is inappropriate. They are discs of the shape of a circular double concave lens, being thicker at the circumference than in the centre. Their size bears no proportion to the of the animal; but the average size varies in different animals. They are larger in man than in most domestic animals; while they are

BLOODRAIN

smaller in the sheep and goat than in the pig, hare, and rabbit. In man, they have an average diameter of 1-3200th of an inch: in the goat, of 1-6366th of an inch.

In the blood, there are also colourless nucleated corpuscles of a spherical form, which are rather larger than the red corpuscles, and are similar to the particles found in lymph and chyle.

The red corpuscles in human blood have a sp. gr. of 1.0885; and as the sp. gr. of the serum, in which they are diffused, is 1.030, they have a tendency to sink in it. The corpuscles may thus be collected and examined in serum, which does not dissolve the colouring matter. The *colouring-matter*, to which the term *hematosine* has been applied, is an organic principle containing nitrogen and iron in some peculiar state of combination. It has an intense colouring power; and on the breaking of the outer membrane of the corpuscles, the red colour is diffused and communicated to water. The proportion of iron has not been accurately determined; but it is supposed to form from 0.43 to 0.5 per cent. of the dried corpuscles, or 6 per cent. of the pure colouring matter.

An aqueous solution of the colouring-matter, when recent, has an intensely red colour. When heated to about 150°, it is coagulated, the liquid assuming a brown colour. Nitric acid and chlorine destroy the red colour, turning the liquid brown and greenish brown. Weak alkalis in small quantities have no effect upon it. In excess they darken it. Neutral salts produce no change in it. Alcohol and tannic acid render the solution turbid, but do not destroy the red colour.

The following table shows the results of an analysis of human blood by Lecanu (*Annales de Chimie et Physique*, vol. xlviii.); considered *quantitatively*, it must only be taken as a mean or approximate result.

Water	780.145
Fibrine	2.100
Colouring matter	133.000
Albumen	65.090
Fat and oily matter	3.740
Extractive matter	1.790
Albumen combined with soda	1.265
Chloride of sodium	
potassium	
Carbonates } of potassa	8.370
Phosphates } and soda	
Sulphates }	
Carbonates of lime	
" } magnesia	
Phosphate of lime	2.100
" } magnesia	
" } iron	
Peroxide of iron	
Loss	2.400
	1,000.000

Bloodrain. A vegetable growth which sometimes appears in the form of bloodred spots on cooked provisions, and which is re-

BLOODROOT

ferred to the Algæ, under the name of *Palmella prodigiosa*, but which, according to Mr. Berkeley, seems rather to be one of those conditions of mould which under various colours are common on paste and other culinary articles. The spots consist of myriads of extremely minute granules.

Bloodroot. The root of the *Sanguinaria canadensis*, the juice of which is of a red colour.

Bloodstone. A jaspery variety of Quartz, of a dark green colour, variegated with red spots like drops of blood (whence the name). It is frequently made into seal and ring stones and other small ornamental articles. [HELIOTROPE.]

Certain kinds of hæmatitic iron-ore were called Bloodstone by the ancients, because (as Theophrastus says) they seemed 'as if formed out of congealed blood.' At the present day the term is more especially restricted to the 'lar' and compact hæmatite which is made into burnishers, and which possesses the valuable property of laying on gold and silver leaf without fraying or tearing it; it should be of a deep red colour, free from flaws, close-grained, and susceptible of a fine polish. Galicia in Spain is the country from which the finer descriptions of this variety of hæmatite are almost exclusively obtained.

Bloom. The lump of wrought iron in puddling mills, which leaves the furnace in a rough state, to be subsequently rolled into the bars or other material into which it may be desired to convert the metal; the blooms are already partially converted into wrought iron by passing under the shingling hammer.

Blowers. In Coal Mines. [FIRE DAMP.]

Blowing Machines. Instruments for producing a current or blast of air, chiefly for the purpose of exciting the combustion of fuel, and producing a great heat. The common bellows is an instrument of this kind; but for certain processes in metallurgy, as in smelting and refining ores, the intermittent blast produced by the single bellows is prejudicial, and even in the double form of the machine, as used generally by blacksmiths, the defect is not altogether remedied. Various contrivances have been employed for the purpose of producing a continuous and equable blast, though depending generally on the principle of forcing air into large cylinders or air-chests by means of a force air-pump, and allowing it to escape by ejection pipes under a regulated pressure. For the regulation of the pressure the air may be forced into a vessel inverted in a reservoir of water; but as the air is chilled by its contact with the water, the water regulator is found to be objectionable for large blast furnaces, and a weight is employed. Machines on this principle are in use at every foundry and great engine manufactory; and they have this advantage, that a number of forges may be supplied from the same air-chest. (Ure's *Dictionary of Arts, Manufactures, and Mines*, art. 'Metallurgy'.)

Blowpipe. An instrument by which a small jet of air is directed laterally into the

BLUE STONE

flame of a lamp or candle, so as to divert it in a long slender cone upon a piece of charcoal or other substance so placed as to receive it. When a flame is thus urged by the blowpipe, the extreme heat is just at the tip of the outer white flame, where the combustion is most perfect, and where substances are rapidly burned or oxidised; whilst the interior blue flame, in consequence of its excess of combustible matter, abstracts oxygen from, or *reduces*, substances. So that several metals, when thus heated before the blowpipe, are alternately oxidised and deoxidised by being placed in the outer and inner flame. The blowpipe is of important service to the chemist in enabling him to ascertain easily and quickly the effects of intense heat upon a variety of substances; and he frequently has recourse to it in order to distinguish metallic and earthy minerals from each other, and to ascertain in a general way the nature of their component parts: it is, in fact, a most important auxiliary in all cases of qualitative analysis. Several treatises have been written on the use and indications of the blowpipe: the reader is especially referred to Faraday's *Chemical Manipulation*, sect. iv. § 3.

Blubber. The cellular membrane in which the oil or fat of the whale is included. [BAL-LENA.]

Blue (A.-Sax. *bleaw*; Ger. *blau*). In Painting, the colour of the sky. It is one of the original or prismatic colours, and is of many sorts: the principal are ultramarine, prussian blue, blue bice, and indigo.

Blue Iron-ore. [VIVIANITE.]

Blue John. The name commonly given by the miners of Derbyshire to the beautiful variety of compact Fluor Spar, which is made into vases and other ornamental articles. The finest kind for these purposes is found at Tray Cliff, near Castleton.

Blue Lead. Is a name applied by miners to Galena, in contradistinction to White Lead-ore, Anglesite, &c. The name *Blue Lead* is also given to a pseudomorphous variety of Galena, found in Cornwall and elsewhere, accompanying the carbonates of lead and copper.

Blue Light. A composition consisting of saltpetre 4 parts, sublimed sulphur 2 parts, red orpiment 1 part. It is used for signal purposes.

Blue Mould. The name given to *Aspergillus glaucus* as it appears growing on cheese, and perhaps applied also to some other kindred moulds. Though often purposely induced on cheese, it may be considered as of doubtful wholesomeness.

Blue Pill. *Pilula hydrargyri*. Consists of mercury triturated with conserve of roses and the powder of liquorice root till the globules disappear and a homogeneous bluish-grey pill-mass is obtained: it contains one-third of its weight of mercury.

Blue Prussian. [PRUSSIAN BLUE.]

Blue Stone or Blue Vitriol. Sulphate of Copper.

BLUFFS

Bluffs. High banks presenting an abrupt form towards the sea or river.

Boa (Lat.). A genus of serpents, with the transverse scutæ of the abdomen and tail in a single row, and without a rattle or spur at the end of the tail. Some species attain an immense size; but the large serpents brought to this country, and called *boa constrictors*, are generally *Pythons*, and natives of Asia. The true boas are from South America.

Boar. [Sus.]

Board (A.-Sax. bord). A word applied usually to certain individuals in a collective capacity, who are intrusted with the management of some public office or department. Thus the Commissioners of Customs, the Committee of the Privy Council for the Affairs of Trade, the Commissioners of Excise, &c. when assembled to transact the business of their respective offices are styled the Board of Customs, the Board of Trade, the Board of Excise, &c. But the term Board is used also in a more general sense, being applied to any individuals appointed by competent authority to deliberate on or superintend the operations of any private business or speculation.

Board. Timber cut up into thin stuff is usually known as board, though in the case of elm and fir the thicknesses called *boards* become *planks* when applied to mahogany or oak. The term board is applied familiarly to a piece of timber of 9 inches wide and 3 inches thick; but strictly speaking the term should not be applied to a greater thickness than 1½ inch. The word board is used to express also the purposes to which timber may be converted in a building, such as barge board, eaves board, floor board, &c.

Boarding. In Naval language, is the act of attacking a hostile ship by the introduction of armed men upon its decks. The operation is always attended with risk, from the confined nature of the battle-ground, ignorance of the enemy's dispositions, &c. Unless the boarding is in the nature of a surprise and therefore conducted by boats, it is essential as a preliminary that the ships should be laid alongside or athwart each other.

Boat (A.-Sax. bāt). A term used in a general sense to denote any small ship or vessel, whether open or decked, and which may be propelled by oars, or by sails, or by steam. Boats are accordingly of very different forms and constructions, according to the different purposes they are intended to serve. Under this term are comprehended barges, cutlers, pinnaces, yawls, &c. [SHIP; STREAM NAVIGATION.]

Boatswain (A.-Sax. bātswan). The second of the three warrant officers of a man-of-war; he has charge of the boats, rigging, anchors, and cables. It is his duty to *turn the hands up*, or summon the whole crew, whenever they are required for any duty. He should from the nature of his duties be an active man, and a thorough seaman. The *boatswain's mates* assist the boatswain, summon the watches or

BOG

other portions of the crew to duty, and inflict punishments.

Bobstays. Stays or strong ropes to keep down the bowsprit during the plunging of the ship, and against the upward action of the head sails (jibs, fore-staysail, &c.), and to sustain the action of the stays or ropes, which keep the foremast, fore-topmast, &c., and therefore the main-topmast, from falling aft. They are necessarily very strong; they are attached to the bowsprit by *collars* placed about two-thirds of its length outside, and to the hull of the ship, by passing through holes in the *cutwater* or projecting head, and make an angle of about 30° more or less with the axis of the bowsprit. They are often made of chains.

Boccia Light. A form of gas-burner invented by Boccia, in which two concentric metal cylinders are so placed over the flame, and within the usual lamp glass, as to modify the combustion and increase the proportion of light.

Boeland (A.-Sax.). Land held by *book* or charter. Lands so held were estates of perpetual inheritance, as distinguished from *folc-land*, which, as being the property of the community, might be granted to persons in the *folc-gemot*, but which at the expiration of a given term reverted to the community. Folc-land was subject to many burdens from which boeland was exempt. The latter obliged the owner to contribute only to military expeditions and the repair of castles and bridges—an obligation expressed by the term *Trinoda necessitas*. The word folc-land, falling into disuse, was replaced by the term *terra regis* or crown land. (Allen, *On the Royal Prerogative*; Hallam, *Middle Ages*, chap. viii. note 9.)

Bodenite. A kind of Allanite found in prismatic crystals at Boden, in the Saxon Erzgebirge.

Body (A.-Sax. bodig). In Geometry, is synonymous with *solid*. Thus we say the five regular *bodies*, or five regular *solids*. [SOLIDS.]

Body. In Physics, is a term applied to any portion of matter of which the existence can be perceived by any of our senses. According to the Peripatetics, body is composed of *matter, form, and privation*. In modern physics, body is regarded as an agglomeration of material particles. According to the different forms in which matter exists, bodies may be *solid, liquid, or gaseous*.

Body of the Place. [ENCEINTE.]

Bog (Gael. *soft*). The name given in Natural History to a collection of peat earth and vegetation, or to an accumulation of peaty soil under the influence of rain or of running waters. The soil thus collected is composed principally of silica and vegetable fibre. On the Continent, bog earth is worked for peat under the names of *lager veen* and *hoog veen*, the lower or the higher peat, according as the mass may occur with respect to the water line of the country; the *hoog veen* is usually considered to be the more valuable of the two, on account of the smaller quantity of water it contains. Many

BOG BUTTER

human remains and relics of animals have been discovered in bogs, which possess a strange antiseptic power.

Bog Butter. A variety of Hartite or Guayaquilite found in the peat-swamps of Ireland.

Bog Earth. A soil consisting chiefly of sand and vegetable fibre; it is often accumulated in considerable quantity where waters have deposited the mud in boggy places. Many American shrubs and other plants and flowers will thrive only in such or similar soils, so that bog earth is in great request for such purposes. It may, to a certain extent, be artificially imitated by mixing the cuttings of grass with the mud of ponds and a sufficient quantity of sharp sand.

Bog Iron-ore. A hydrous oxide of iron common in flat marshy localities. It is of variable composition, containing from 20 to 70 per cent. of peroxide of iron: the protoxides of iron and manganese are often present, and sometimes as much as 10 per cent. of phosphoric acid and organic matter.

Large quantities of the skeletons of Infusoria (*Grallionella ferruginea*) have been found by Ehrenberg in the Bog Iron-ores of Prussia, the Ural, and New York. The infusoria of the Bog Iron-ore are stated by Ehrenberg to be only one-thousandth of an inch in diameter, or half that of a human hair—consequently a cubic line would contain 1,000,000,000 of those minute organisms. [LAKE ORE.]

Bog Manganese. Earthy Manganese or *Wad* [which see].

Bog Ores. [BOG IRON-ORE; LAKE ORE; &c.]

Boghead Coal. A highly bituminous variety of the Parrot or Cannel Coal of Scotland from the higher part of the Scotch coal-field worked at Boghead, near Bathgate in Linlithgowshire.

The bituminous varieties of cannel pass into bituminous shale by insensible gradations, so that it is impossible to draw a line of separation which shall properly limit the use of the term *coal*. The Boghead is one of these substances, much more valuable for gas-making and for the oils and paraffine obtained from it, on slow distillation, than for fuel in the ordinary sense of the term. Dr. Andrew Fife found a picked specimen to yield on analysis 70 per cent. of volatile matter and 30 per cent. of ash. [BITUMINOUS SHALE; CANNEL COAL.]

Bohea. [TEA.]

Bohemian Bole. A yellowish red variety of Bole.

Bohemian Diamond. A name sometimes given to colourless and transparent Rock Crystals, when cut and polished.

Bohemian Garnet. [CARBUNCLE; PYROPE.]

Bohemian Ruby. [ROSS QUARTZ.]

Bohemian Topaz. Transparent yellow Rock Crystal.

Böhmertia (named in memory of Böhmert, a German botanist). A genus of Nettleworts,

BOILER

consisting of herbs or shrubs closely allied to the true nettles, but not having stinging hairs. *B. nivea* is the Rhea or Chinese grass-cloth, the fabric so called being prepared from the inner bark of the stems. It is a small shrub remarkable for the whiteness of the under surface of its leaves. It is much cultivated for its fibre in China and India. Other species yield useful fibres.

Boiler. The term used in Civil Engineering to express the vessel in which water is boiled for the purpose of raising steam for the machinery of a factory; or a closed vase of wrought iron, or copper, in which water is vaporised, and employed in the gaseous form, to impress movement upon steam-engines or other machines. In this case, the effect of the machine is dependent upon the conversion of the water into vapour, and this power is the only one used. The boiler must then satisfy certain conditions which are of the highest interest. Thus, as the motive power of the engine depends upon the excess of the pressure of the steam in the boiler, it is necessary that the latter should be of sufficient strength to resist it; and as the heat applied is always more or less costly, it is important that the fireplace should be constructed so as to employ the whole of it. The danger of allowing the boiler to sink so low as to let the metal come in contact with cold water admitted suddenly, must also be carefully guarded against, and this necessity gives rise to many contrivances of a complicated nature.

The parts of a boiler, ordinarily, are: the furnace, consisting of the fire-bar, the ash pit, and the bridge; the boiler properly speaking, with its steam chest and pipe, and its safety-valves; the apparatus for ascertaining the level of the water and its pressure in the boiler, which consist in the steam gauges, and the pressure gauge or manometre; the float and tubes; and the chimney. Each of these parts has a separate use, and it requires a special adaptation to the class of engine under consideration; for the purposes of ordinary commerce some of the parts may be omitted, but they must all be present in steam-engines, and must be modified according to whether the boiler is intended to work at high, or low, pressure. Many varieties have been proposed in the manner of heating the water contained in the boilers; and as the heat developed in the furnace acts more by the extent of the surface to which it is applied than by its intensity, every form has been recommended for this purpose in its turn; but, after all, it seems that local considerations are of more weight in deciding the kind of furnace than any abstract ones, and the style which might suit at one place would not suit at another. The principal forms of furnace are referred to in the subsequent parts of this work, and the same remark may be extended to the other details; because there are no universal principles regulating their construction, which would admit of being laid down authoritatively. The most common

BOILER PLATE

forms of boiler used are the waggon-head, the cylindrical, the tubular, and the locomotive boilers [all which see]: the parts which are connected with the level of the water, the pressure of the steam, and the draught in the chimney will be found investigated under **WATER and STEAM GAUGES; BRINE COCKS; FLOATS; and CHIMNEY.**

For heating water for the purpose of warming buildings, the boilers are very frequently made of copper, or of cast iron, when the quantity of water to be heated is small, or of wrought iron when it is greater; the latter material is, however, so generally used that it is alone worthy of notice.

Boiler Plate. The description of wrought iron which is rolled expressly for the purpose of boiler-making; though by a common error it is made to apply to the plates which are used for ship-building, bridges, or girders; all of which are now said to be constructed in boiler plates. The average resistance of boiler plates is taken at about 20 tons on the square inch, and the safe weight to which it may be loaded is usually taken at 5 tons on the square inch; the effect of riveting upon the structure is considered to be equivalent to a reduction of strength corresponding to that of the area occupied by the rivets. The Board of Trade require that the strength of wrought-iron structures should be at least equal to the above quantity of 5 tons per square inch.

Boiling Point. The temperature at which liquids are rapidly converted into vapour with the phenomena of *ebullition*. Thus the boiling point of water is 212°; of alcohol, 176°; of ether, 90°; of oil of turpentine, 316°; and of mercury, 662°; these being the respective temperatures at which these bodies continuously pass into the state of vapour.

Bole (Gr. *βαλος*, a clod of earth). An earthy argillaceous mineral chiefly consisting of hydrated bisilicate of alumina, reddened by peroxide of iron; as is the case in *Armenian Bole*, which is used in tooth-powder and as a colouring material. It is found in Saxony, Silesia, Bohemia, Sicily, &c.

Bole of Meis. A yellow kind of Bole, which contains carbonate of lime, and effervesces with acids.

Bolero. A peculiar species of dance very popular in Spain, and so called from the name of its inventor.

Boletic Acid. An acid contained in the juice of the *Boletus pseudo-ignarius*.

Boletus (Lat.). A genus of *Fungi*, many large species of which spring from the sides of trees when the rind is decayed, forming firm fleshy masses, which are generally smooth on the upper side, and pierced with holes on the lower. The spawn of such plants often forms what is called dry-rot, insinuating its fine delicate filamentous ramifications between the tubes of the wood, forcing them asunder, and so destroying the cohesion and solidity of timber. *B. ignarius* and *B. foenicularius* are the fungi which, when cut into thin slices,

BOLTS, NAVAL

dried, and prepared with saltpetre, form common amadou, or the German tinder of the shops. *B. tuberosus* is used in Sweden as a substitute for cork. *B. bovinus* is said to be a favourite food of oxen, deer, swine, and some other animals; it is even used for human food. *B. edulis*, though not much used in this country as an article of food, is in Hungary preferred to the mushroom.

Bollards. Are large posts set up on either side of a dock, or basin, for the purpose of having attached to them the blocks through which are reeved the hawsers used in hauling vessels into and out of the dock.

Bologna Phials. Small flasks or phials of unannealed glass which fly into pieces when their surface is scratched by a hard body, as by dropping into them a fragment of flint; whereas a bullet may be dropped into them without injury.

Bolognese School. In Painting, there were three periods of the Bolognese school; the Early, the Roman and the Eclectic. The first was founded by Marco Zoppo in the fifteenth century, and its great master was Francia. The second was founded in the sixteenth by Bagnacavallo, who spread the Roman style in Bologna; the masters of this period were Primaticcio, Pellegrino Tibaldi, and Niccolò dell' Abate. The third was founded by the Carracci at the close of the sixteenth century; its object was to unite all the excellences of the preceding schools [PAINTING]; hence it is called the *Eclectic school*. Among the principal painters which it numbered were Domenichino, Lanfranco, Guido, Schidone, Guercino, Albani and others known as the *Carracceschi*. Their merits were purely technical, and their style Academic.

Bolognian Stone. A kind of sulphate of baryta found near Bologna. After having been heated with charcoal, and then exposed to the light of the sun, it becomes strongly phosphorescent, and remains so for some time.

Boloretin. An earthy-looking resin, contained in the fossil fir-wood of the peat bogs of Denmark.

Bolster. In Nautical language, has three meanings. 1st. A piece of timber adjoining the hawse-hole, intended to prevent the chafing of the hawser against the cheek of a ship's bow; 2nd. Small pads of painted or tarred canvas placed under the rigging to prevent friction when the spars strain in stormy weather; 3rd. A cylindrical iron block, with a hole through the middle, used as an anvil when holes are being punched in metal.

Bolt-rope. The border of the sails of a ship, to strengthen the canvas and prevent it tearing. Up the sides of a sail it is a *leech-rope*, along the top a *head-rope*, and at the foot a *foot-rope*.

Bolts, Naval. Are cylindrical rods of copper or iron, preferably copper, employed in binding together the timbers or iron plates of which a ship is constructed. They vary from half an inch to three inches in diameter, and

in length from a few inches to many feet. Their heads are of diverse patterns, according to the object for which they are intended.

Bolthead. A globular flask with a tubular neck, used in the chemical laboratory.

Boltonite. A kind of Chrysolite, which differs from the other varieties of that mineral in being a silicate of magnesia, instead of a silicate of magnesia and iron. It occurs at Bolton in Massachusetts, in granules and irregular masses disseminated through limestone, seldom with any traces of crystalline form, and of a colour varying from ash-grey to yellowish-white: the darker colours change to yellow on exposure to the weather.

Bolus (Lat. from Gr. *βῆλος*). A very large pill; or a medicine formed into an olive-shaped mass, not too large to be swallowed.

Bomb. [SHELL.]

Bomb Vessel. [KETCH and MORTAR-BOAT; GUN-BOAT.]

Bombardier (Fr., from Low Lat. *bombarda*). The name given to the lowest rank of non-commissioned officers in the artillery.

Bombardiers. [BRACHINUS.]

Bombardment. A term signifying the showering down upon a town or fortress shells, carcasses, rockets, hot shot, and other incendiary missiles, to burn or destroy the buildings and kill the inhabitants. It takes effect more upon the civilians than the military, as the latter in any well-constructed place are lodged in bomb-proof buildings. That a bombardment is of little avail against a governor who is firm may be seen from the memorable bombardment of Prague during twenty-two days in 1757 by Frederick of Prussia; also those of Williamstadt by the French in 1793, and Gibraltar in 1780-81. Before bombarding a town, it is customary to give notice, to allow women and children to leave it.

Bombax. A genus containing many species of large soft-wooded trees, whose capsules are filled with a fine cottony substance enveloping the seeds. It belongs to the natural order *Sterculiaceæ*, of which *Bombacæ* is a subdivision. In this order, which is allied to the Malvaceæ plants, it is associated with the celebrated *Baobab*, and many more gigantic inhabitants of tropical forests. The *Bombax* trees are remarkable for forming huge buttresses, projecting from the parent trunk. The quantity of cotton yielded by these trees is enormous; but it is unfortunately of too short a staple to be used for manufacturing purposes. This substance bears the name of *Silk-cotton*.

Bombazine (Gr. *βόμβυξ*, a silkworm). fabric of which the warp is silk, and the weft (or shoot) worsted. It is chiefly made in black, and is an article of mourning for female dress.

Bombic Acid. The acid contained in the silkworm, especially in its chrysalis state. It is supposed to resemble formic acid.

Bombite. A mineral with all the characters of Touchstone, of which it is, probably, only a variety. It is found in the environs of

Bombay (whence the name).

Bombycilla. A genus of omnivorous Passerine birds, of which the Bohemian wax-wing (*Bombycilla garrula*) is an example, and an occasional winter visitor of Britain.

Bombylius. A Linnean genus of Dipterous insects, and now the type of a family (*Bombyliidæ*), characterised by the great length of the oral instruments, which form a long and slender proboscis; body thick, short, hairy; thorax gibbous; wings extended horizontally; halteres exposed; antennæ short, approximate, composed of three joints, the last the longest, thickened and terminating obtusely; legs long and slender. The insects of this family have a rapid flight, and are very active; they subsist entirely on the nectar of flowers. They are of small size, and mostly exotic, affording types of many genera, of which only *Bombylius* proper and *Phthiria* afford British examples.

Bombyx (Gr. *βόμβυξ*, a silkworm). A Linnean genus of Lepidopterous insects, now the type of a family (*Bombycidæ*), including many genera of nocturnal and postmeridian moths. These have been arranged under the following sub-families: *Hepialidæ*, *Notodoxidæ*, *Arctiidæ*, and *Bombycidæ* proper.

Bona (Lat. *goods*). In Law, *Bona notabilia*, goods to the value of five pounds, whereof if a man died possessed in two dioceses respectively his will must formerly have been proved before the metropolitan of the province. [PROBATE, COURT OF.] *Bona vacantia*, goods without owner, such, for instance, as goods casually lost: the property whereto, the law of England and some other countries vests in the crown.

Bona Dea (Lat.). In Roman Mythology, a goddess described as sister or daughter of Faunus. The *Bona Dea* had two sanctuaries at Rome, the one on the Aventine, the other near Bovillæ (Cic. *pro Milone*, 31), but her rites were generally solemnised in the house of the consul or prætor. In the celebration only women participated. The violation of these mysteries by P. Clodius in the house of Cæsar, his trial, and his acquittal, which he had purchased by bribery, are well-known facts. (Cic. *Att.* i. 12.)

Bonassus. [BISON.]

Bond (A.-Sax.). In Building, the disposition of the materials in a wall in such a way as to exhibit homogeneity of structure. There are many ways of producing this effect, which are known technically by the following names. The *English bond* is used in brickwork where all the headers of a course of bricks are laid in one way, and all the stretchers in the course over it are laid in the other, so that the union of the bricks is made by the reverse positions of the several parts in the successive courses. *Flemish bond* is the one used in brickwork where the headers and stretchers are alternately laid in the same course, so that the union is effected in the course itself. When stonework is employed, *band stones* are used, which run through the whole thickness of the wall at right angles to the face, for the purpose of binding the wall together in the direction of its thickness; and in mixed structures timber

BOND

is used as a *bond course*, being worked in the wall in the progress, for the purpose of tying it together in a longitudinal direction. In slating, the term *bond* is sometimes applied instead of lap, and it signifies in such cases the distance between the nail in the under slate and the lower edge of the upper or covering slate.

BOND. In Law, a deed whereby the obligor, or party binding himself, obliges himself, his heirs, executors, and administrators, to pay a certain sum of money, called the penalty, to another (the obligee) at a day appointed. There is a condition added, that if the obligor does some particular act the obligation shall be void, or else remain in full force. In case this condition is not performed, the bond becomes forfeited or absolute at law, and charges the obligor while living; and after his death the obligation descends on the heir, who (in default of personal assets in the hands of the executor or administrator) is bound to discharge it, provided he have real assets by descent. The condition is usually (although not necessarily) included in the same deed, and at the foot of the obligation.

A bond without a condition is termed *single* (or *simplex obligatio*); and it becomes single by forfeiture, on non-performance of the condition. At law, the whole penalty mentioned in the bond was recoverable on such non-performance. But by the interposition of equity the obligee was discharged from paying more than the sum to which the obligor was reasonably entitled; viz. his principal, interest, and expenses, if the bond was for payment of a debt; or the damages accruing to him, if it was for the performance of a stipulated act. But by 4 & 5 Anne c. 16, it was enacted that in case of a bond conditioned for payment of money, the payment of the sum due, with interest and costs, even though the bond be forfeited and suit commenced thereon, shall be a full satisfaction and discharge; and on this footing the law now stands.

A bond on which neither principal nor interest has been demanded for twenty years cannot be sued on, unless some acknowledgement shall have been made by writing, signed by the party liable or his agent, or unless the party entitled to sue has been under disability (stat. 3 & 4 Wm. IV. c. 42).

In a bond where several are bound severally, the obligee may, at his election, sue all the obligors together, or all of them apart, and have several judgments and executions: but he shall have satisfaction but once; for if it be by one only, that is sufficient to discharge the debt.

Bond, English. In Architecture, that disposition of bricks in a wall wherein the courses are alternately composed of *headers*, or bricks laid with their heads or ends towards the faces of the wall, and in the superior and inferior courses of *stretchers* or bricks, with their lengths parallel to the faces of the walls, as in the margin, in which the upper is called the heading, and the lower the stretching course.

BONE

Bond, Flemish. In Architecture, that disposition of bricks in a wall wherein each course has headers and stretchers alternately, as in the margin.

Bond Stone. In Architecture, a stone running through the whole thickness of a wall at right angles to its face, for the purpose of binding the wall together in the direction of its thickness.

Bond Timber. In Architecture, timber worked in with a wall as it is carried up, for the purpose of tying it together in a longitudinal direction while the work is setting.

Bone (Ger. *bein*; Dutch, *been*). An important part of the higher orders of animals [ANATOMY], forming the solid support of their fabric, and protecting the vital organs, such as the brain and the heart and lungs, from external pressure and injury. In the human skeleton there are commonly enumerated 260 distinct bones. They, however, admit of classification under three heads; namely, *long* or *cylindrical* bones, such as those of the extremities; *broad* and *flat* bones, such as those of the skull; and *short*, *square*, *irregular*, or *solid* bones, such as the vertebrae, and those of the wrist and instep, and the patella or kneecap. The first bones are generally filled with marrow, and are admirable specimens of strength of structure with the least possible weight. The bones are covered by a membrane called *periosteum*, by which the ramifications of blood-vessels and nerves pass into the bone. In the growth of a bone, the cartilaginous portion, as it has sometimes been called, is first formed, and the earthy or indurating part is afterwards deposited. The soft parts consist of modified gelatine and albumen; and the hard portion is composed of phosphate of lime and carbonate of lime, with small quantities of other salts. The animal matter of bones amounts on an average to about half their weight, or, when dried, to between 30 and 40 per cent.; so that they contain a large relative proportion of nutritive matter. The bones, including their animal matter, are the most durable parts of the animal fabric; hence the proposal of storing them up, as occasional sources of nutriment; for not only is the cartilaginous portion unimpaired in bones which have been kept dry for many years, but it has even been found perfect in bones of apparently antediluvian origin. The best mode of extracting the nutritious part of bone for human food consists in grinding it fine, and subjecting it with water to a heat of about 220° in a digester; or the earthy part may be removed by dilute auriac acid. When dogs and some other animals devour bones, the nutritive part is abstracted by their gastric juice, and the earthy part is voided in their excrement, forming what was formerly called *album græcum*. [BONE EARTH.]

When bones are submitted to destructive distillation, the animal matter which they contain is abundantly productive of ammonia;

BONE BED

hence a copious source of that alkali and its compounds. The residue is a mixture of the earthy part of the bone with charcoal, commonly termed *ivory* or *bone black*.

Bone Bed. Several deposits of different geological age have been thus named. The most remarkable are two; first, a singular mass of scales, fins, jaws, teeth and coprolites of fishes, found in the Upper Ludlow rocks, and secondly, a thin but well-marked accumulation of reptilian bones between the lias and new red sandstone at Aust in Gloucestershire. The latter is now recognised as belonging to the Triassic period.

Bone Black. The black carbonaceous substance obtained by heating bones to redness in a close vessel. When deprived by the action of hydrochloric acid of the phosphate of lime with which it is blended, it yields one of the most valuable forms of *animal charcoal*, as a decolouring and deodorising material.

Bone Dust (or ground bones). Has long been used with the best effect as a manure. It is usually applied to light or turnip soils, which it has rendered in no ordinary degree productive. The importation of bones from distant countries to be used as manure is carried on to a great extent. Bone dust is now used very generally after being subjected to the action of sulphuric acid. The superphosphate of lime, as it is then called, is more immediate in its effect on fertility; and 3 cwt. of it will produce as great an increase in the current crop, as 12 to 20 bushels of the original bone dust formerly applied could do. It is generally applied to the turnip crop, to mangold wurzel, and occasionally to grass lands.

Bone Earth. The residue of bones which have been calcined so as to destroy the animal matter and carbon, and become converted into a white porous and friable substance, composed chiefly of phosphate of lime. According to Berzelius, 100 parts of human bones are composed of 51.04 phosphate of lime, 11.30 carbonate of lime, 2 fluoride of calcium, 1.20 soda and chloride of sodium, 1.16 phosphate of magnesia, and 33.30 animal matter. Albumen, gelatine, and fat constitute the animal part of bone, the greater part of which remains in the form of a tough cartilage when bones are steeped in dilute moric acid.

Bone Liqueur. The aqueous portion of the distillate of heated bones. It is a very impure and dilute solution of various ammoniacal salts, resembling *spirit of hartshorn*.

Bonito (Span.). The name of a species of Scomberoid fishes (*Thynnus Plumis*, Cuv.), common in the tropical ocean, and well known to voyagers for its persecution of the flying-fish (*Exocetus volitans*) and flying squid (*Loligo sagittata*).

Bonnet. [FORTIFICATION.]

Bonsdorffite. A hydrated variety of Iolite of a dark olive-green or greenish-brown colour, found at Abo with Cordierite. Named in honour of the chemist Bonsdorff.

Bonzes. The priests of the religion of Fo are so called by Europeans; especially in

BOOK-KEEPING

China, the Burman Empire, Japan, and other districts of Eastern Asia.

Booby. The English name of a genus of *Pelicanide*; they are also called *gannets*, *noctuides*, and *solan gese*. [NODDIES.]

Book (A.-Sax. boc). The general name of almost every literary composition, but in a more limited sense applied only to such compositions as are large enough to form a volume. Short and fugitive pieces are denominated *pamphlets*, in contradistinction to books, which are of greater length, and embrace more general or permanent topics. According to their sizes and forms, books are distinguished as folios, quartos, octavos, duodecimos, &c. The materials of which books have been composed have differed much in different nations, and in different stages of civilisation. Plates of lead and copper, bricks, stone, and wood were anciently employed for this purpose. At a later period the bark of trees formed the chief material, as is indicated by the meaning of the word, which in some languages are employed for the term *book*. [LINER.] Materials for books were afterwards derived from the Egyptian plant papyrus; but as the demand increased, more durable materials were sought for, and leather, made chiefly from the skins of goats or sheep, was employed for this purpose. Next followed the use of parchment, on which the ancient MSS. were chiefly written; but all these systems were swallowed up by the invention of PAPER [which see], which took place about the thirteenth century, and facilitated the circulation of knowledge to an incalculable extent. The first books were in the form of blocks and tablets; but when flexible materials came into use, it was found more convenient to roll them up in scrolls, called by the Romans *volumen*. Books were anciently written on one side only of rolls of paper or parchment. When written on both sides they were called *opisthograph*. (Plin. iii. 5; Juv. i. 5). The blank backs were usually stained with the saffron colour obtained from the cedrus (Ovid, *Trist.* iii. 1. 13). To save the expense of writing materials it was unfortunately sometimes the custom to wash out what were considered unimportant writings and use the paper or parchment again. These were then called *palimpsests*. [PALIMPESTS.]

Book-keeping. In Commerce, the art of recording, in a regular, concise, and systematic manner, the transactions of merchants, traders or other persons engaged in pursuits connected with money. It has not only the authority of experience to recommend it, but that of some of the sagest observers of human affairs; Dr. Johnson remarks, 'that the counting-house of an accomplished merchant is a school of method, where the great science may be learned of ranging particulars under generals, of bringing the different parts of a transaction together, and of throwing at one view a long series of dealing and exchange. Let no man (he adds) venture into large business while he is ignorant of the method of regulating books. never let him imagine that any degree of

BOOK-KEEPING

natural abilities will enable him to supply this deficiency, or preserve a multiplicity of affairs from inextricable confusion.' There are two modes of keeping books of account; the one by what is termed *Single* and the other by *Double Entry*. Both are in very general use. The system of single entry is chiefly confined to the business of retail dealers; it is much the simplest method of book-keeping, consisting of only a day-book and a ledger. In the day-book the dealer enters his sales and purchases, and in his ledger he carries the former to the debit of his customers, and the latter to the credit of the merchants who supply him with goods. By making at any time a list of the sums due to him by his customers, and of those due by him to wholesale merchants, the retail dealer may, after adding to the debts due to him the value of his stock on hand, arrive at an approximation to the real state of his debts and assets. This, however, is but an imperfect and unsatisfactory mode of book-keeping; and, therefore, in the case of wholesale and mercantile business, where extensive and multifarious transactions have to be recorded, recourse is had to the system of *double entry*. This system possesses all the advantages of single entry, besides being so complete and comprehensive in its principles, and so certain in its results, as to admit of universal application. It may with equal advantage be adopted in the most limited as well as in the most extensive, in the most plain and simple as well as in the most intricate and complicated concerns.

No very authentic accounts exist of the origin of book-keeping. The double-entry system appears to have been first practised towards the latter part of the fifteenth century, in Venice and other towns in Italy, then the great emporium of the mercantile world; and from this circumstance it acquired the name of the *Italian method of book-keeping*. The first known work on the subject was by Lucas de Borgo, published in 1496; and the first in the English language a treatise by John Gough, a printer, published in London in 1543. The advantages of the system, and the soundness of the principles on which it is based, soon became apparent; for we find it was adopted in England and France early in the sixteenth century, and has continued to be more and more practised down to the present day.

The great objects of a good method of book-keeping are to exhibit transactions as they occur, in the most minute detail, and ultimately in the most condensed form; advancing from the earliest stage to the latest by such clear and lucid steps as at all times to admit of every fact being traced in its progress, and security being obtained at every step against omission or error. For the attainment of such important objects, no mode of book-keeping has hitherto been devised at all approaching to the perfection of the Italian system by double entry. Every transaction in business is twofold; there can be no receipt without a pay-

ment, and no purchase without a sale, and consequently by presenting the same event or fact on both sides of the books, whence the name of 'double entry,' the entries being simultaneous, become corroborative of each other. The circumstance of every transaction being entered on both sides of the ledger affords one of the most valuable results derived from the system of double entry, namely, a test of accuracy; inasmuch as the entries on the credit side must be equal to the entries on the debit side, otherwise the books will not balance.

The three principal books required under the Italian system of double entry are, a cash book, journal, and ledger. In the first of these every transaction is recorded where money forms one of its elements, and in practice these transactions are by some book-keepers carried direct from the cash book to the ledger without being passed through the journal at all. The journal, however, forms a most important part of the system. It exhibits a narrative of every transaction of which an actual transfer of money does not form one of the elements, arranging the facts in as simple and condensed a form as correctness and intelligibility will admit of, and the results of those entries in the journal are afterwards introduced into the ledger, which thereby becomes a sort of key to the detailed history of every transaction; whilst at the same time it furnishes a luminous compendium of the whole. In like manner when the cash transactions are passed through the journal they are at stated periods classed and arranged in a condensed form, and thence transferred to the ledger. This plan of introducing the cash transactions into the journal is considered much the best system, though attended with a little more trouble to the book-keeper, as it affords great facilities in balancing the books and testing the accuracy of the ledger, more particularly when the recent improvements upon the form of the journal, which were originally suggested by the late Mr. Jones, are adopted. By the plan referred to, the journal is advantageously ruled with four cash columns, two upon the left-hand side for *entries debtor*, and two upon the right for *entries creditor*; and all the transactions being connected either with *personal* and *property* accounts or *nominal* accounts, such as charges, profit and loss, and so forth, they are classed accordingly in the columns on the Dr. or Cr. side of the journal respectively; and as the debit entries are at all times equal to the credit entries, the aggregate of the two columns on the Dr. side must tally with the aggregate of the two on the Cr. side of the journal. This too is found in practice to be a most useful check against posting the entries to wrong accounts in the ledger; for on balancing the books, by taking the amounts Dr. and Cr. posted to personal and property accounts, and the amounts Dr. and Cr. posted to nominal accounts in the ledger, and comparing them with the total amounts in the corresponding columns of the journal, it will be seen whether they agree: if they do

not, it demonstrates that some entries must have been erroneously posted, which can then only be discovered by collating the books; but if the amounts do agree, then it affords at least strong presumptive evidence that the whole of the entries have been carried to the proper accounts. Experience and practice are occasionally suggesting minor improvements upon the forms of the cash book, journal, and ledger, to suit particular cases, as well as upon the subsidiary books required for gathering together the facts preparatory to their being transferred in a condensed form into the journal; and indeed an intelligent book-keeper may accomplish much by a judicious classification of the facts in the auxiliary books; but the fundamental principles of the double-entry system of book-keeping, notwithstanding such occasional facilities and improved arrangements in the working of it, remain perfect and unchanged; and after the length of time during which they have successfully withstood all attempts at innovation or change, it may safely be affirmed that the system is the best hitherto discovered.

We have already stated that the double-entry system of book-keeping admits of universal application; and we may now observe that it is not confined to merchants' accounts, but is equally applicable to government accounts. One great desideratum in a system of book-keeping for government accounts is centralisation, which can alone be attained by a proper and well-organised method of condensing the facts or elements of the accounts; and the Italian system unquestionably affords the most efficacious means of collecting and grouping the widely scattered elements of government accounts in a concise and intelligible shape, and ultimately exhibiting them in the clearest and most perfect state.

Boom (Ger. *baum*. a tree or pole). A Nautical term, signifying a long pole run out from any part of a ship to stretch the bottoms of particular sails; whence *jib-boom*, *main-boom*, *studdingsail-boom*, &c.

Boom. In Marine Fortification, signifies a strong chain or cable stretched across the mouth of a harbour or river, to prevent the enemy's ships from entering, and having a number of poles, bars, &c. fastened to it; whence the name.

Boomerang. A familiar though little understood missile, of a curved form, which in the hands of a native of Australia performs marvellous feats, while in those of a European it is inert and intractable. The savage by practice knows precisely how to poise as well as project his familiar missile; and in this secret of the *balanced* centre consists Sir Thomas Mitchell's application of the principle of the boomerang to the propulsion of vessels. Great results are anticipated from the scientific application of this simple principle, suggesting as it does a means of adapting a surface revolving round a centre, so that it presents to equal pressure a uniformity of resistance, be-

cause the spaces described by a body in falling are proportional to the squares of the times. When the same surface is placed vertically and set in rotary motion through fluids, it is subject to a similar law, and when in the plane of a screw, it is equally poised obliquely. Thus we have in this form equilibrium, and equal resistance, and equal strength, the propeller being balanced when it is first formed on its axis. Hence, under any degree of velocity centrifugal action is converted into concentric action by the peculiar manner of balancing the surface round the centre of rotary motion.

Boops. A genus of fishes of the order *Acanthopteri*; most of them occur in the Mediterranean.

Boort or Bort. A kind of Diamond, generally of a spherical shape, and apparently formed of a confused mass of interlaced and twisted parts, like knots in wood. In consequence of this peculiar structure, it cannot be cut like the ordinary diamond, and is only of use for polishing other stones, after it has been broken and reduced to powder in a mortar.

Boötes (Gr. a ploughman). A name given to the constellation Arcturus, as early as the Homeric age. (*Odys.* v. 272.)

Boracic Acid. This substance is abundant in the crater of Volcano, one of the Lipari Isles, and around the fumaroles of Tuscany [*SASSOLINI*]; it also occurs in some minerals. In its usual scaly state it is a *hydrate*, composed of 56.4 per cent. of dry acid + 43.6 water. It is used for making borax, and was formerly known under the name of *Homburg's sedative salt*. [*BORON.*]

Boracite. Native borate of magnesia. It occurs in cubes, inclining to grey, yellow, or green, with a vitreous lustre, and opaque or more or less translucent. Small but perfect crystals are found at Kalkberg and Schildstein, near Lüneberg, in Hanover, in beds of Gypsum; and it is also met with massive at the salt-mine of Stassfurt in Prussia.

Boraginaceæ. A group of corollifloral Exogenous plants resembling the genus *Borago*, after which they are named. They usually have a mucilaginous sap, in which nitro exists in small quantities. Boraginaceous plants are mostly herbs of the northern temperate regions, and they have sometimes very handsome flowers, arranged in a gyrate manner. Forget-me-not (*Myosotis*), Bugloss (*Echium*), *Anchusa*, and various species of *Lithospermum* are well known favourites either among wild or cultivated plants. Most of them have their leaves covered with asperities, whence their old name of *Asperifolia*; and some, as *Anchusa tinctoria*, *Lithospermum tinctorium*, and several others, yield a deep purple dye from their roots.

Borassus. A genus of Palm-trees, belonging to the series usually called Fan Palms because their gigantic leaves are formed of plates radiating from the top of the petiole, and folded up after the manner of a fan. *Borassus flabelliformis*, the Palmyra Palm, is an Indian species, with a trunk from thirty to fifty feet

BORATE OF LIME

high, and leaves with from seventy to eighty rays. The Hindus consider it the king of trees. An intoxicating liquor, called toddy, or palm wine, is obtained by fermenting its sap, which yields sugar in considerable quantity.

Borate of Lime. [DATHOLITE; HAYESINE; SASSOLIN.]

Borate of Soda or Borax (Low Lat.). This salt is composed of 36.58 per cent. of boracic acid, 16.25 soda, and 47.17 water. It is found native in some of the lakes of Thibet and Persia, and is brought to this country from India under the name of Tincal, which after purification becomes the *refined borax* of commerce. Large quantities are, also, made from the boracic acid of the Tuscan lagoons, by combining it with soda. Borax forms variously terminated prismatic crystals, which are slightly efflorescent, and soluble in 18 parts of cold and 6 of boiling water. When heated, water of crystallisation is driven off, and the residue fuses into a transparent mass called *glass of borax*. Borax is chiefly used by workers in metals as a flux, and to aid the process of soldering; it is also employed in medicine, and in the manufacture of glass and artificial gems.

Borates. Salts of boracic acid.

Border or Bordure (Icelandic, bord). In Heraldry, according to French heralds, an honourable ordinary, which should occupy a third part of the shield. In English blazonry, it has generally been considered as a mark of difference to distinguish one branch of a family from another. It surrounds the field, is of equal breadth in every part, and occupies one-fifth of the field. When there is a chief on the coat, the bordure is supposed to run under the chief; but it passes over other ordinaries, as a fess, &c.

Bore. A word used to express the sudden rise of the tide in certain estuaries, as in the Severn.

Boreas. In Grecian Mythology, the son of Astræus and Eos, and usually worshipped as the god of the north wind. The assiduity with which the worship of Boreas was cultivated at Athens proceeded from gratitude, the north wind having on one occasion destroyed the fleet of the Persians when meditating the invasion of Attica. A similar cause induced the inhabitants of Megalopolis to consider Boreas as their guardian divinity, in whose honour they instituted an annual festival. Boreas was usually represented with wings dripping with golden dew-drops, and the train of his garment sweeping along the ground.

Boring. The operation of piercing the earth for the purpose of ascertaining the nature of the subjacent strata, or of bringing to the surface any underground springs. A great variety of tools are employed for this purpose, such as augers, jumpers, misers, ball and socket valves, according to the strata traversed. Of these a good description will be found in the work by M. Déroussée, *Guide du Sondeur*, or in the treatise on *Well-digging* of Weale's series, in which also will be found an account of the

BORNITE

arrangements for working the tools at a great depth from the surface, and of the results of some of the most celebrated operations for obtaining a water supply in this manner. The success of the Artesian wells thus found to exist under London, Paris, and Rouen; the great success of the boring at Grenelle, Passy, and at Warren Farm, have indeed been sufficient to justify the favour with which this process is regarded; but unfortunately, the public always hesitate about the preliminary studies necessary to insure such results, so that the invention of well-boring is treated as an empirical study, and one to be left entirely to *practical* men.

Boring has been well applied for the purposes of fixing the posts of electric telegraphs; for the tying down bolts of suspension bridges, and for sinking the tubes now used for the foundations of buildings to be erected in running water, &c.

Boring Worm. The *Teredo navalis* is so called. This is a worm which enters wood in salt water, and there expands until it attains the size of a finger; it bores the wood, into which it enters, during the whole of the passage between high and low water mark, completely riddling it in those parts, and causing an infinite amount of damage to ships, or to piers, docks, and harbours, wherever wood enters the construction in the shape of piles, cills, &c. It is supposed that creosote is the only effective preservative against the ravages of this animal, though a coating of copper nails has been strongly recommended; but there is danger of the animals finding their way into the wood between the small spaces left by the heads of the nails, and then the destruction of the wood is inevitable. Of course great care and attention is required in the application of the creosote (which in the best work is injected after the extraction of the moisture from the wood) under a vacuum, to the extent of 4 lbs. per foot cube; it requires a pressure of about 130 lbs. on the square inch to insure this quantity entering.

It is supposed that the *teredo* only attacks wood when it is exposed on shores able to yield the bicarbonate of lime; at any rate, it is far more destructive in them than in others. The animal also appears to have a distaste for the sewerage waters of towns, perhaps because they are not impregnated with the salts of sea water.

Borneo Camphor. A variety of camphor obtained from the *Dryobalanops Camphora*.

Bornite. A name given (after De Born) to a variety of Telluric Bismuth found at Field's gold-mine in Dahlonega, Georgia, in a quartz-vein, associated with gold and auriferous Iron Pyrites; also at José in Brazil, in marble. It occurs in foliated masses, which have a crystalline structure and split into thin plates, the colour and lustre of which resemble polished steel. The mineral is flexible, sectile, and soils the fingers. The name Bornite has, also, been given by Brooke and Miller to Purple Copper.

Borocalcite. Native borate of lime. [HAYESINE.]

Boron. The base of boracic acid, discovered by Davy in 1807. It may be procured by heating dry boracic acid with potassium. It is a dark olive-coloured substance, a non-conductor of electricity, insoluble in water, infusible, and of a specific gravity = 2. Heated to redness it burns into *boracic acid*, which consists of 11 boron + 24 oxygen.

Borough. A town possessed of certain municipal institutions. The name is derived by some from the Saxon word *burg*, meaning an enclosed place; by others from another word of the same language—*borg*, meaning pledge, which was applied to some of the associations for mutual liability established by the Saxon law. Boroughs, in the sense of the definition above given, must, in some shape, have existed very early in this as well as in other countries; but the origin as well in constitution as in name of the existing municipal system in England can be traced no higher than Anglo-Saxon times, and the general and connected history of English boroughs does not begin before the Conquest.

According to Domesday Book there were in England at that time eighty-two boroughs, including cities, differing considerably in the extent of their franchises as well as in their customs and mode of government; but agreeing in this general character, that they were communities established chiefly for the purposes of trade, endowed to that effect with certain franchises, such as that of a fair or market, and possessing as boroughs a special jurisdiction exercised in the borough court-leet, and exclusive of the jurisdiction of the hundred. Some of them then held, and all were capable of holding, lands in common; and in respect of such land they held, as did also each burgess in respect of his own tenement, of some lord, by a species of tenure called *burgage tenure*, which was, in fact, similar to the ancient tenure in common socage, i.e. tenure by rent or service certain. This continued to prevail in boroughs after the general imposition upon other lands of the feudal or military service. The lordship of the land of the borough, and of the different tenements which it contained, must have belonged in the first instance to the lord of the manor within which it was situate; but all boroughs, in contemplation of law, held their franchises of the king.

Great obscurity prevails as to what was originally the internal constitution of boroughs, as to how far it was popular or not, and how far also it was or was not uniform. It is certain that as early as the date of Domesday Book the proportion between the number of burgesses and that of other inhabitants was very different in different boroughs. Much perplexity also arises on this subject from the intermixture in the same place of the guild and borough franchises [GUILD], which prevailed to such an extent that the guild-merchant, which appears to have been an incorporation or an

association by license of all trades within the borough, is by some considered as identical in its constitution with the borough itself. It is certain, at any rate, that the guild-merchant, though it did not in the first instance constitute the borough, yet in many places usurped its franchises and government, and finally assumed its name; so that, with the exception of *burgage tenure*, which still prevailed in some few places, and of birth, which was common to both institutions, the other modes of obtaining the freedom of a borough—i.e. those of apprenticeship, purchase, or gift—were introduced into the municipal system from the guild-merchant. Distinct from this in their relations and contests with the community of the borough at large were the guilds of particular trades, which succeeded in London in engrossing and parcelling among themselves, under the name of liverys, the whole of the municipal franchises.

All borough rights, being exceptive, rested either upon charter, or upon prescription which supposes a charter. Some few of such charters were granted by Saxon kings; but they became much more frequent after the Conquest, the style and purport of these early documents being simply that of a grant to the *men* and *burgesses* of such a place of certain franchises, whether relating to trade, as that of a fair or market or exemption from toll, or to jurisdiction, such as a commission of the peace and the right of holding sessions, which was first granted to any borough by Richard I. In the reign of Henry VI. a remarkable alteration took place in the style of these royal grants, as then first were granted, it is said, charters of incorporation, strictly so called: though previous to that time boroughs, or the governing bodies that represented them, enjoyed all the privileges of a corporation, and since that time many have continued to enjoy them without any such special grant. From that time forth, however, the history of boroughs becomes identical, except as to the parliamentary franchise, with that of municipal corporations. These charters of incorporation did not pretend to regulate the internal constitution of boroughs. This constitution very generally assumed the form of a government by a small and in great measure self-elected body, which in most cases succeeded in engrossing not only the whole administration, and in a great degree the enjoyment of the borough franchises and property, but the right also of granting, according to rules more or less arbitrary, admission into the subordinate body of burgesses or freemen. And even that body, where it existed, which was not always the case, was small in proportion to the whole number of inhabitants. It was the great object of the charters granted by the Tudor sovereigns to sanction and confirm the usurpations of these municipal oligarchies, with the view apparently of throwing the representation of boroughs (a right which, conferred in the first instance by Edward I., had since been extended by fresh grants, and was then becoming of considerable importance) into the hands of such as were most likely to

be easily guided or controlled, either by the crown itself or by the great lords upon whose support it reckoned. The latter began about the same time to connect themselves with the boroughs, in the neighbourhood of their possessions, under the honorary title of high stewards. The exclusive system of municipal government, which attained its height during the Stuart dynasty, continued unimpaired until it was effectually put an end to by the Act for the Regulation of Municipal Corporations, passed in the year 1835. For an account of this change, as well as of the other remarkable incidents in the history of our municipal institutions, which have happened from the time of the Tudors to the present period, see *CORPORATIONS*; and for an account of the *representation* of boroughs, and particularly of the *reform in their representation*, see *PARLIAMENT*.

The account above given of English boroughs, both as to their origin and constitution, applies in all its general features to Scotch boroughs; with this qualification, that the government by close corporations was in Scotland thoroughly and more generally prevalent until the reform in them. This was effected by a law preceding by a year the Municipal Corporation Act applicable to this country, and resembling the latter in almost everything but this, that it made the qualification for burghership identical with that required to give a vote in the election of members, namely, the occupancy of a house of the yearly value of 10*l*.

In Ireland the municipal system, as it now exists, is of considerably later origin than in Scotland or in England. It was transplanted, and gradually introduced from the latter country; and though with the same names and form of constitution as then existed there, had much more in it of a political character, being intended in the first instance as a support to the English against the Irish, and in later times to the Protestant against the Catholic, and was so used to the neglect of functions more properly municipal, which have therefore in many instances been intrusted to other hands by local Acts of Parliament.

Borough, English. In Law, is a customary mode of descent of lands in some ancient boroughs and manors, by which estates descend to the owner's youngest son; or if he has no issue, to his younger brother. [DISCENT.]

Bos (Lat.). A genus of hollow-horned Ruminants which is found extensively distributed over the Old World. Five species are known to zoologists. The *Bos Taurus* is well known as our domestic ox, many varieties of which have been produced by domestication. With respect to the wild original of our numerous herds there is yet some obscurity; less, however, than hangs over the origin of some other domesticated species. The wild cattle which approach nearest to the tame are those which inhabit the forests of the north-east of Europe, and the white cattle, which are still preserved in a state of purity at Craven, at Chillingham

Park, and in Scotland. These are both referred to the species called *Bos Taurus*, or *Bos Urus*, or *Urus scoticus*; but there is much reason for supposing this species to have been the domestic ox reverted to a state of nature. Another well-marked variety of this species is the Brahminy bull, characterised by the hump on the shoulders and the hanging dewlap (*Bos indicus*).

The other known wild species of ox are the Gayal of India (*Bos gaurus*); the Yak of the mountains of Central Asia (*Bos grunniens*); lastly, there are the Buffaloes, which, though anatomically less distinct than the Bisons from the typical *Boves*, yet differ from the oxen as a group in many points. They have larger horns, which sometimes form a horny covering of great thickness to the whole frontal region; and they approach the Pachydermata in the thickness of the skin and the thinly scattered coarse hair. They frequent marshy grounds, and feed on a ranker herbage than the ox. The flesh of buffaloes is coarse, and they are used chiefly as beasts of draught or burden. The two best marked species are the Indian or Arnee buffalo (*Bos arnee*), and the South African buffalo (*Bos caffer*).

Bosjesman (Dutch, *man of the wood*, or *bushman*). A name given by the Dutch colonists to some roaming tribes akin to the Hottentot, in the vicinity of the Cape of Good Hope. The description given by Governor Janssens of this people represents them as so deeply sunk in barbarism as to be unacquainted even with the construction of huts or tents. They are of a dark copper complexion, small in stature, and of a singularly malicious, wild, and intractable disposition.

Boss (Fr. *bosse*). A term applied in mediæval Architecture to the piece of stone, usually carved in a fanciful manner, which covers the intersection of a series of arches. It is commonly finished with a flower, or a human masque, and is one of the most characteristic specimens of mediæval decoration.

Bossage (Fr.). In Architecture, any projection left unwrought on the surface of a stone for the purpose of afterwards receiving a sculptural decoration, which is generally the last part of the work executed.

Bostrichus (Gr. *βόστροχος*). A genus of Coleopterous, Nyctophagous, or wood-boring insects, now raised to the rank of a family (*Bostrichidae*), including amongst its numerous genera three which contain species whose ravages have called forth the attention of the legislature both in this and other countries in consequence of the extensive destruction of valuable timber caused thereby. The species in question are the *Bostrichus ligniperda*, *Scolytus destructor*, and *Tomicus typographus*; but the two latter are the most mischievous, and astonish us by the amount of damage produced by insects of so small a size. The elm-tree is the object of attack to the *S. destructor*; while the *T. typographus* restricts its operations to the fir. The females attack the crevices of the bark,

and perforate it in diverging lateral channels; in which from sixty to eighty eggs are deposited. At the end of fifteen days the larvæ are hatched, and forthwith commence the work of destruction, each gnawing a serpentine gallery between the bark and the wood, and gradually enlarging its burrow until the period when it is ready to pass into the pupa state, when, having finally become a perfect beetle, it directly bores through the portion of the tree which remains between the wood and the outer bark, and escapes through a small circular aperture in the latter. This emergence of the perfect insect takes place in the month of May; and in seasons favourable to their development they appear in swarms, and rise to a height exceeding that of the trees, and may be carried by the wind to another and distant part of the forest. The impregnation of the female takes place in the air; so that wherever they alight they are ready to recommence the work of destruction. The chief precautions and remedies which experience has suggested are to cut down the trees which are once attacked, immediately to bark them and to burn the bark, and to remove all felled timber without delay.

Boswellia (named after Dr. Boswell of Edinburgh). A genus of Indian trees belonging to the natural order *Amyridaceæ*, one species of which, *B. thurifera*, yields the resin called Olibanum, which seems to be a corruption of Laban, the name given by the Hindus to this plant.

Not. The name of the larvæ of the Dipterous insect of the family *Estridæ* [which see].

Botanic Garden. A garden devoted to the culture of a collection of plants, with reference to the science of botany. The legitimate object of gardens of this description appears to be to collect and cultivate, at the public expense, all the species and varieties of plants that can be cultivated in the given climate, with or without the aid of glass; and then to distribute these to private individuals throughout the district by which the botanic garden is supported. The most complete system of this kind ever established appears to have been that of France soon after the Revolution. All the botanical articles that could be procured from other countries were sent to the botanic garden at Paris; and after they had borne seeds or been propagated there, the progeny was distributed among the provincial botanic gardens, of which there is one or more in every department. After being propagated in the provincial botanic gardens, the seeds or progeny were given out, free of expense, to all who in the district to which the garden belonged thought fit to apply for them. As the useful species and varieties were not less attended to than those which were cultivated only in a scientific point of view, the greatest facilities were thus given to the spread of every useful grain, pulse, culinary vegetable, and fruit, over the whole of France.

Botany (Gr. *βοτάνη*, herb or grass). That branch of natural history which relates to the vegetable kingdom; not merely including the nomenclature and classification of plants, as some have supposed, but embracing all the phenomena of vegetable life in their widest extent.

One of the most important departments of Botany is that called *Organography*, or the *Structure (Organisation) of Plants*. This comprehends whatever relates to the various forms of tissue of which plants are anatomically constructed; it explains the exact organisation of all those parts through which the vital functions are performed; and it also teaches the relation that one part bears to another, with the dependence of the whole upon the common system. Without a perfect knowledge of Organography no systematical arrangement can be understood; for, being that part of science in which the laws of the symmetry of parts are comprehended, it must necessarily be the basis of all theory of classifications: nor can Descriptive Botany, which may be called the language of the science, have any logical precision, or be intelligible, unless the mind is distinctly impressed with the fundamental laws of this branch of study. Physiology itself, the highest branch of all natural science, depends so absolutely upon an exact knowledge of the structure of parts, that any attempt to investigate the important laws of vegetable life must necessarily be abortive without a strict acquaintance with the more important details of organisation. And by this is not meant merely a general idea of external form, or a vague notion of internal anatomy, but the most precise knowledge that the nature of the subject will admit.

Connected with this branch of study is what German botanists call *Morphology*. The word Morphology signifies literally the 'science of changes or transformations.' As applied to botany, it embraces a subject of enquiry which, to all those who know the importance that attaches to comparative anatomy in the animal kingdom, cannot fail to be peculiarly interesting. It has been clearly made out that all those parts which are familiarly known under the name of leaves, flowers, and fruit, are constructed, in all cases whatsoever, upon a simple uniform plan, out of one single organ in different states of modification and combination; and that there is no other difference between the flower of a rose and that of a nettle than what arises from modifications and combinations of this origin—which is the leaf. If it be doubted whether, considering the anomalous character of some of the lower orders of plants, all vegetables are without exception formed upon one and the same plan, it is impossible not to admit that, at least in all Phænogamous plants, the flowers are composed of the same elements; that these elements are arranged in conformity to a few simple laws (far less variable than their appearance seems to indicate), and the study of which constitutes the basis of the theory of botany. These laws are so evident in a great number of cases, that we

scarcely pay attention to them; but curiosity is at once excited when they seem to be violated. Exact observation, however, shows that in such cases they are only masked; that is to say, an unusual application of two or three different laws produces an apparent anomaly, which is easily explained by a reference to the numerous cases of degeneracy, abortion, and cohesion with which the vegetable kingdom abounds. In such instances as this the botanist may be compared to the mineralogist, who discovers the primitive forms of crystals by means of their secondary forms. We are so accustomed to talk of plants bearing leaves and flowers and fruit, and it is so evident to our senses that extremely different organs really do exist under such names, that it seems inconceivable that parts so very dissimilar should all be only leaves in different states; or that the pure white petals of the lily, the rich red flowers of the rose, the sweet-smelling blossoms of the jasmine and the orange, or the long trumpet-shaped corollas of the honeysuckle, should all be leaves; or that the stamens in which the fertilising powder is locked up, the pistils which are destined to receive the influence of the pollen, the ovules that they contain, and finally, the fruit which is the result of the action of the two last, are all so many parts formed out of one common organ, which in a very particular and frequent state is what we call a leaf. Botanists do not mean to say that he who eats an apple, or an orange, or a peach is in a state of mental delusion, and that while he fancies himself to be enjoying the pleasure of gratifying his palate by the most delicious flavours he is really only chewing the leaves of these plants; but they assert that those appendages of a plant which are commonly called the leaves have a peculiar anatomical structure, and a certain relation to the stem on which they

borne, and being developed according to certain fixed laws, are always arranged upon a certain and uniform plan with respect to each other; and that all the other organs, whether calyx, corolla, stamens, pistils, or fruit, have an anatomical structure essentially the same, bear the same relation to the axis that they grow upon, are developed according to the same laws, are arranged upon the same certain and uniform plan with respect to each other, and, finally, are constantly becoming transformed into leaves of the ordinary appearance, thus losing the condition in which they are usually found, and reverting to their structural type. The admission of such propositions as these does not render our notions of the distinctions between the various organs more obscure than it was before, as some would assert; but on the contrary it enables us the better to understand the real nature of the organisation of any part, and the plan upon which the most complicated arrangement of these organs has been effected. For example, who is to explain how it happens that buds occasionally spring from the axils of petals or sepals, that anthers are found bearing ovules, that branches push forth from the centre of pistils, that petals become antheriferous and

stamens petaloid, unless the proposition is admitted that all those apparently different parts are formed upon a common plan, the type of which is a leaf, and are all therefore convertible into each other?

Another leading branch of the science is *Physiology*, or the department which treats of the vital actions of plants. While Organography is applicable to objects whether living or dead, Physiology solely refers to them in a state of vitality. There is scarcely any part of natural history more difficult than this, if rigorous demonstration is required, nor, at the same time, one upon which there was in former days a greater degree of mere speculation. Like many other of the higher departments of natural philosophy, hypothesis preceded experiment; so that in the earlier history of botany we find scarcely a trace of those ideas which modern observation has developed in a very remarkable manner.

It was not till after the invention of the microscope that even an imperfect knowledge of vegetable anatomy could be gained; and only when this great step was taken, vegetable physiology began to establish itself upon a sure foundation. Consequent upon this discovery has been the accumulation of a considerable amount of positive knowledge of a world of organised beings having nothing in common with the race of man, and with which we cannot communicate in the slightest degree; that have no volition by which we may occasionally regulate our judgment; whose texture is so frail that it cannot anate them out the destruction of life; whose functions are performed within an opaque dense covering that excludes everything from our view; and which finally are so exceedingly simple in their organisation, and have so few different organs with which to execute their functions, that we are lost in amazement at effects so complicated and forms so various being brought about by means that are so eminently so inadequate. The world has learned from the vegetable physiologist, not only that plants breathe, feed and digest, and how the functions of breathing, feeding, and digesting are carried on; they have also ascertained by what means an increase in their dimensions is brought about, how their want of locomotive power is compensated, and by what precise means their reproduction and multiplication are so wisely ordained as to be placed beyond obstruction by any natural impediments. In short, the exact use of every part of every plant, various as their forms and uses doubtless are, has been ascertained; and we are now entitled to say of plants as of animals, that their kingdom is rendered subject to the power not only of man's physical energy, but of his mental resources.

Perhaps no part of the creation illustrates more forcibly than the vegetable world, the admirable skill and foresight with which all the phenomena of the universe have been adapted by the Great Author of our being to the accomplishment of the objects for which they have

BOTANY

been severally intended. Take, for example, vegetable tissues. What can be conceived more wisely prepared! The cellular tissue, capable of indefinite extension, possessing also prodigious compressibility, its particles cohering either firmly or loosely according to circumstances, its sides composed of a most delicate membrane, through which fluid and gaseous matter passes readily in every direction, is destined to form the principal mass of the vegetable, and to execute all those functions with which absorption and respiration are connected. The fibrous tissue, composed of myriads of threads compactly combined into bundles, dispersed through the cellular substance, admirably supplies the place of bones and nerves in the animal economy, affording strength, solidity, and elasticity to the most delicate parts; while the vascular tissue, exclusively intended for the reception and rapid transmission of gaseous and liquid matter from the roots to the extremities, is most wisely contrived, and most carefully prepared by its spiral structure, for extending and turning, as the cellular substance develops, to those parts where the peculiar matter that it contains is most required. Here there is no confusion of offices; each part has its peculiar function assigned to it, for which it has been especially destined and for which it is alone adapted.

Then look at the leaves. The leaves are the organs in plants that correspond with the stomach in animals; that is to say, it is in them that the fluid matter taken up by the roots, and injected into them from the stem, is digested and inspissated, and separated into the nutritious and excremental portions.

Digestion takes place in leaves chiefly by the absorption of carbonic acid, the emission of oxygen, and the evaporation of water. If this process were to be carried on without any provision against the variations which are constantly occurring in the state of the atmosphere, it is easy to conceive that in excessively dry weather leaves would lose all their moisture and constantly become parched up, while in wet weather they would be so gorged with moisture as to burst from distension. In order to prevent the occurrence of this, Nature has enclosed leaves in a cuticle scarcely pervious either to air or moisture; and in this cuticle she has placed numerous mouths, called stomates, which have the power of opening and closing, according to the state of either the atmosphere or of the leaf itself, to regulate the absorption or respiration of either water or air. And in order to expose the tissue lying beneath this cuticle to the greatest possible atmospheric influence, the leaf is not a solid mass, as it appears to be, but is traversed in all directions by passages terminating in the mouths and opening into cavities, where the air both of absorption and exhalation can freely circulate and pass in or out so long as the mouths permit it. Nor is this all. Many leaves are constantly submerged beneath the surface of water, where they are never exposed to atmospheric vicissitudes can

never evaporate, and being cut off from the air, can neither absorb carbonic acid from the air, nor discharge oxygen back into it in return. It is therefore obvious that the curious provision that has been made for the regulation of the action of aerial leaves would be useless in submersed ones; and accordingly we find that the latter have neither cuticle, nor mouths, nor cavernous parenchyma, and are thin but solid plates, the whole surface of whose cellular substance is in direct contact with the water, from the air contained in which the leaves must exclusively derive their nutriment.

The employment of the same kind of organ, in different forms, for the purpose of effecting the varied objects that are to be provided for in the vegetable economy, is another and a most remarkable instance of the consummate wisdom and wonderful simplicity discoverable in all these things. Upon the birth of a plant one or two leaves are developed, which feed the infant until it is strong enough to develop one or two more. These last not only, like the first, proceed without exception from opposite sides of the stem or body, but are so placed as to alternate with the first. This goes on with unvarying uniformity, as long as growth continues; so that, view a plant in whatever way we will, whether in its earliest state, or at the most advanced period of its existence, it will always be seen to exhibit the same beautiful symmetry as the most highly developed animals. One side counterpoises the other; whatever is discoverable on one side, equally exists upon the other. If it is necessary that a protection should be formed for securing the young and tender buds against cold, the leaves surrounding the buds suddenly contract into hard scales, perhaps exude a resinous or gummy matter, or clothe themselves in a deep covering of wool, and an impenetrable living shield is thus interposed between the bud and danger. If a plant is to be rendered more beautiful to the eye, its leaves again contract, the spaces that usually separate them are obliterated, new colours are assumed, and petals are created resplendent with brilliant hues or exhaling the softest perfumes. If propagation is to be effected, the petals contract into stamens, their central substance becomes disintegrated in the form of pollen, and the interior of each grain of the latter is resolved into that living matter of which in a state of cohesion all nature is composed. A few leaves are rolled together in the form of pistil, the apex of the midrib becomes denuded, and young buds are developed at the base. A grain of pollen, the disintegrated tissue of the flowering leaf, falls upon the denuded apex of the fructifying leaf, absorbs moisture from it, distends, and finally produces a tube of inconceivable fineness, which abstracts from the pollen its impregnating matter, some of which descends the midrib into the womb of the leaf, and thence entering the young buds that are developed at its margins, is finally hatched, and appears at last in the form of embryo plants. Such is the simplicity

BOTANY

of the arrangements that are observable in the most perfectly formed, the most elaborately constructed plants. In the lower orders, the mode of formation, development, and propagation is still more simple. A vesicle elongates and distends until it becomes a tube; from the end of this tube more vesicles are generated which themselves give birth to others, and thus a simple branching plant is formed. In the inside of each tube by degrees a green matter is deposited; and after a certain period has elapsed, it is emitted in the form of little green vesicles, like that from which the plant originally sprung, and themselves capable of developing as new plants. In certain tubes, this dissolution takes place in a much more astonishing manner; not into inert green matter, but into moving particles, having all the properties of spontaneous motion and animal existence. Soon, however, the moving particles elongate; thus losing their power of motion and becoming plants, to whose laws of life they ever after submit.

These are far from being all the divisions into which Botany, or the study of the vegetable kingdom, may be subdivided; although they are no doubt among the most interesting. Besides these there is *Taxonomy*, or the *Principles of Classification*. It would be of little use that a man should know anatomy, and structure, and comparative organisation, and have informed himself of all the leading principles of physiology; if he were unacquainted with the names of the objects he had been studying, and were consequently incapable of communicating his knowledge to others. At least, of whatever use it might be to himself, it could not be of advantage to anyone else. But if he is acquainted with the names of known objects, and if he understands the rules of classification, he can then render his information available to others as well as to himself. And in like manner he can at all times determine what is known about any particular plant that he may have been studying; or if it be a kind previously unknown, he can find its place in the system, and by publishing a description of it, he can fix it there for the information of others.

But there is another way of looking at the utility of classification, which shows that what may to some appear but a dry and barren subject, is in reality one of the most important branches of the science. No man can know all things relating to such a science as this—few men can learn many things; for this reason it is of importance that a means should be discovered of judging of what is unknown by what is known; and that by judiciously selecting a moderate number of objects for particular study, the enquirer may have a ready and in no way burdensome means of forming a clear knowledge of the whole vegetable kingdom. This is not difficult, if attention be paid to the doctrine of affinities. Everyone must have seen that some species of plants are more like each other than they are like different species. Without

considering the matter botanically, everyone must, for example, have remarked that a radish is more like a turnip than it is like a currant bush, that a pea is more like a bean than an apple, and that a cherry blossom is more like an apple blossom than a horse-chestnut. These are rude instances of affinity on the one hand, and discrepancy on the other; but they are nevertheless perfectly explanatory of what is meant. Botanists find that classification may be founded upon a consideration of general resemblances and differences; and that by carefully examining the characteristic organs of plants, those species may be classed most nearly together which have the greatest degree of resemblance and the most perfect constitutional agreement. Now, this being the case, it follows that a knowledge of one species is to a great extent a knowledge of many; and that a correct idea of a single individual of a group in the classification, provided that individual is well selected, involves to a considerable extent a knowledge of all the other species of the same group. For example, in the *Cruciferae*, consisting of perhaps 1,600 species, the study of the common radish, the mustard, or the cress, will give the student a very accurate general knowledge of the remaining number, because they are all close modifications of the same forms. Again, the common potato, rightly understood, represents the greater part of *Solanaceae*, or at least of some hundred species belonging to that tribe; while the dead-nettle, *Lamium album* or *rubrum*, stands as the representative of some 2,000 or more species called *Labiatae*. This would be of eminent importance if its advantage stopped here; but when it is considered that the properties of plants also accord in a very remarkable manner with their structure, and that those which are most closely approximated in a classification will most nearly resemble one another in their sensible properties, the advantages to be derived from a study of the laws of affinity cannot fail to be clearly perceived. For example, to use the same illustrations as before, anyone acquainted with *Cruciferae* would know that there is no instance of a poisonous or deleterious plant in the tribe, a point of great importance to be aware of; on the contrary, he would know that if they had succulent roots, they might be employed like the radish, and that their leaves were antiscorbutic; but if he met with an unknown plant, which, from its resemblance to the potato, he knew belonged to *Solanaceae*, he would at once reject it as poisonous, or at least suspicious, unless it had tubers filled with fecula, when he would except that portion, because all fecula is wholesome, however poisonous the trees or plants may otherwise be that produce it, provided the deleterious matter that lies among it is removed by washing or volatilisised by the action of heat.

It is not, however, any kind of classification that leads to such ends. All artificial systems, as for instance that of Linnæus, are unproductive of such results. It is only the Natural

BOTANY

System of botany from which these important advantages are to be derived.

Another division of the science relates to the meaning of the terms employed; this was formerly called *Terminology*, but now more correctly *Glossology*. It is the least interesting part of the subject; but at the same time it is too important to be passed over lightly, because it is impossible either to understand the writings of botanists, or to make oneself intelligible to others, without being correctly informed of the meaning of the terms peculiar to the science. The state of Terminology at any given time may indeed be safely taken as indicative of the state of the whole science; for in proportion as ideas are multiplied and knowledge rendered exact, the more are the terms required to express those ideas multiplied and their application rendered definite. A curious exemplification of this is to be found in the *Historia Plantarum* of Fuchs, a learned botanist of the sixteenth century. In the glossary prefixed to that work are comprehended only 132 terms of all kinds, many of which refer to measures, and are therefore not appertaining to botany; and of the remainder, 29 belong to modifications of stems, 15 to differences of inflorescence, 6 to the fruit, but not one to any other part of the fructification. In the present state of botany, the terms that relate to the seed alone are probably as numerous as the whole of those comprehended in Fuchs's Glossology.

Another and very distinct branch of botany is that which concerns the rules to be observed in describing and naming plants; or what is called *Phytography*. The great object of descriptions in natural history is to enable any person to recognise a known species, after its station has been discovered by classification, and also to put those who may not have had the opportunity of examining a plant themselves, into possession of all the facts necessary to acquire a just notion of its structure and affinities. It is therefore important that such descriptions should be drawn up according to certain conventional well-known rules, and not according to the caprice of individuals; and this not only for the sake of insuring uniformity of language, and in all cases the same order of treating the subject, but also to prevent descriptions being too general, to fix attention on the most important points of structure, and at the same time to prevent their being more prolix than is really necessary. The rules of description are more especially intended to guard against the latter evil; for no mistake is more common than to confound prolixity with precision.

The last branch into which the study of the science may be divided, is the application of the preceding subjects to the art of discriminating species. This may be called the *Præctice of Botany*, as the former belonged to its theory, and is by far the most difficult part of the subject. There is no difficulty in becoming acquainted with the fundamental principles of the science, because they naturally arise out of

each other, and are dependent upon the just appreciation of a few simple laws, the various combinations of which, upon principles easily comprehended, constitute the differences that exist between organs themselves and their numerous modifications. But the practice of botany, although its study is essentially facilitated by an acquaintance with fundamental principles, and indeed cannot be usefully pursued without it, yet has peculiar difficulties of its own. It is often difficult to recognise organs in consequence of the manner in which they are masked by the modifications they have undergone; their combinations are frequently so intricate that great experience is necessary to enable an observer to judge of them correctly; their minuteness is often such as to render indispensable a use of the microscope, which requires peculiar dexterity and a good deal of practice; and finally the number of species is so great, that to bear in mind their distinctions is a heavy tax upon the memory. Difficulties of this nature are almost insurmountable by a student who is unaided by the experience of a teacher.

At what period of the world botany first began to be studied as a science, has not been satisfactorily ascertained. That in the most remote ages man had his herbs and his roots; that he was acquainted with the properties of one plant, and the uses of another; that he gave them names, and that poets derived many beautiful thoughts from them, was natural enough; but this had nothing to do with botany. The first dawn of that science broke from out of the deep investigations of the nature of matter and mind by the philosophers of Greece. How much they knew, we have no accurate means of judging; but that they knew a great deal of vegetable physiology is obvious from their famous paradox, that plants are only inverted animals—a sentiment which, however strangely it may sound, could only have arisen from an extensive knowledge of the vital phenomena of Vegetation. Nor could the doctrine of Aristotle that all organic matter exhibits a series of development, have been conceived or promulgated, unless the philosophers of his day had possessed a practical acquaintance with vegetation much beyond that of the ages that succeeded.

Happy had it been for those ages if, instead of retrograding in the path of science, or rather stepping out of it altogether, they had only pursued the course commenced by Theophrastus 350 years before Christ. By that naturalist the beginning was made of applying particular terms to particular modifications of structure. He demonstrated the absence of all philosophical distinction between trees, shrubs, and herbs—a distinction upon which his successors were fond of insisting; he speaks clearly of the parenchyma and woolly fibre of wood, the former of which he calls the flesh; and he described accurately the difference between palm wood and that of trees with concentric layers; so that in point of fact the discovery of the difference

between Dicotyledonous and Monocotyledonous wood was made by Theophrastus above 2,000 years ago, although it was never applied to the purposes of systematic division till our own time. Subsequently to this period, botanists almost disappeared for a long season. Those who have been dignified by historians with that title were either pharmacologists, like Dioscorides; or compilers, who, like Pliny, knew little themselves, and misunderstood those whom they copied; or poets, who drew much of the beauty of their language from the charms of nature; or geoponical writers, who were acquainted with those parts of husbandry which relate to physiological botany.

With whom the curious arts of budding and grafting, and striking plants by layers, or propagating them by taking advantage of the divisibility which distinguishes the vegetable from the animal kingdoms, originated, is now unknown; but there is reason to believe that the greater part of the modifications of those processes was in the classical ages as well understood as now. That grafting was extensively undertaken, is obvious from the lines of Virgil:

*Et sæpe alterius ramos impundè videmus
Vertere in alterius, mutatamque insita mala
Ferro pyrum, et prunis lapidosa rubescere corna.*

But, what is much more curious, the delicate process of budding was as scientifically performed at that period as by the most skilful gardener of the present century. Nothing can be more precise than the following elegant description of Roman budding:—

*Nec modus inserere, atque oculos imponere simplex.
Nam qua se medio trudent de cortice gemmæ
Et tenues rumpunt tunicas, angustus in ipso
Fit nolo sinus; huc aliena ex arbore germem
Includunt, udoque docent inolescere libro.*

Again, of crown grafting:—

*Aut rursum enodis trunci rescantur, et alta
Finditur in solidum cuneis via: deinde farces
Plantæ immittuntur: nec longum totipus et ingens
Exit ad oculum ramis felicitibus arbos,
Miraturque novas frondes et non sua poma.*

From the time of Theophrastus all philosophical enquiry into the nature of vegetation ceased for about 1,700 years, during the whole of which time scarcely a single addition was made to the stock of knowledge left by that writer. But with the revival of letters a new direction was given to researches in natural history. Men ceased to content themselves with blindly copying the writers of antiquity, and set themselves in earnest to examine the objects of nature that surrounded them. The woods, the plains, the rivers, the ocean, the valleys, and the mountains, were investigated with an ardour that soon made amends for ancient indifference. The first consequence of this was a discovery of the worthlessness of the greater part of those writers to whom the world had so long been bound in servile obedience. The spirit of enquiry once excited, men speedily learned to estimate rightly the greater value of facts than of assertions; one discovery produced another, and in a few years a new foundation was laid of that imperfect but

beautiful science which constitutes modern botany.

Up to the middle of the seventeenth century, vegetable physiology had been grounded upon observations entirely independent of anatomical investigation. But about this time the accurate enquiries of two naturalists, one an Englishman and the other an Italian, gave a new feature to the study; and what was vague or imaginary in the opinions entertained upon the vital functions of vegetables gave way to conclusions, precise and supported upon the firm basis of careful observation. The nature of cellular tissue, of spiral vessels, of ducts, of woody tissue—the composition of the internal parts of plants, and the functions of the whole—excited enquiry, and received reasonable if not accurate explanations. Collections of facts and of ideas accumulated on all hands, and the confusion that had once been caused by ignorance threatened again to overwhelm the science, in consequence of the rapid addition of new matter which there was no means of keeping in order. Hence systematists sprung up—a race of enquirers to whose labours the present advanced state of botany is no doubt much to be ascribed. That the efforts of the earliest of these writers should have proved unsuccessful, will excite no surprise. With little knowledge of vegetable physiology or anatomy—for it must not be forgotten that for a long time, and even now, vegetable physiology and systematic botany were considered as distinct sciences, and with scarcely any notion of the laws of affinity and metamorphosis—they could not be expected to succeed. We should rather wonder at what they did, than at what they omitted to do. Many of them had great merit, especially John Ray, an English deprived clergyman, and Joseph Pitton de Tournefort, a professor of botany at Paris, who flourished in the latter part of the seventeenth century, and upon whose systems the modern arrangement according to natural orders is essentially founded. This, however, with all others, was for a time eclipsed by another, better adapted to the circumstances of the times, and emanating from a writer who, having the courage and talent to carry reformation into every branch of natural history, imparted a lustre to his peculiar system of classification which has only now, after the lapse of a century, fallen into disuse among men of science.

Charles Linné, or Linnæus, as he is usually called, was a person exactly adapted to the science of the time in which he lived. The various departments of natural history had not at that time anything like their present extensive range, and might without difficulty be investigated by a single naturalist. They were all equally in need of revision and improvement; they all wanted a settled code of laws to reconcile the fluctuating and jarring opinions which at that time prevailed, and above all things the nomenclature of natural history required to be reduced to one uniform standard. For this Linnæus was peculiarly well adapted. Nature had gifted him with a logical accuracy

BOTANY

of reasoning, and a neatness and perspicuity of expression, which carried with them a charm that the world was not slow to appreciate; and these produced the stronger impression, because naturalists had previously been but little accustomed to them. Thus the opinions of Linnæus were received as if oracular, their faults being lost sight of in the splendour which they threw over the whole of the organic world; and he not only established his famous method of arrangement, which for a long time superseded all others, but laid the foundation of the curious laws of morphology, upon which modern botany founds one of its greatest claims to perfection. The notion faintly shadowed forth by Linnæus in his *Species Plantarum*, that all the parts of plants are mere modifications of leaves, became the subject of a special and most original dissertation by the German poet Goethe, in 1790; and though this doctrine was believed by the botanists of that day to be worthy only of the poetical fame of its illustrious author, it is now received, with little change, by every botanist of reputation.

After the artificial system of Linnæus, followed the natural system of Jussieu. Vegetable anatomy became an important branch of enquiry; the researches of Knight and others gave a new character to vegetable physiology; and the early part of the present century saw the science assume an entirely new appearance. Our knowledge of the vital functions of plants reposes upon the sure basis of exact observation and careful experiments; the theory of the plan upon which the organs of vegetation and fructification are severally combined into so many numerous forms is settled upon the clearest evidence; and classifications, to a great degree freed from the trammels of prejudice, have assumed that position in science to which their importance, when rightly studied, entitles them.

The only two botanical arrangements now in use are the Linnæan and the Natural. The former is an attempt at classifying plants according to their agreement in some single characters, without reference to their resemblances or differences in any other respect, just as words are arranged in a dictionary by the accordance of their initial letters. The other is a scheme for placing next each other all those plants which have the greatest resemblance, and at the greatest distance those which are most dissimilar. The distinctions derived from great physiological peculiarities are considered fundamental, and form classes; while characters, derived from diversities of external structure, are subordinate, and valued according to their permanence or frequency, &c. The final result is the making up of the vegetable kingdom into associations, called Natural Orders, which are supposed to consist of genera more closely allied to each other than to anything else. For an explanation of the details of the Linnæan method of classification, the reader is referred to the works of Willdenow and others of that period; and for those of the Natural

method to the writings of Jussieu, Decandolle, and Lindley.

The Classes in the Sexual System of Linnæus, now all but exploded, depend upon the number and relative position or degree of combination of the stamens and styles. The characters of the orders, or minor groups, depend upon the number of the styles, or of the stigmas if there be no style; upon the nature of the ovary; upon the form of the fruit; upon the arrangement of the flowers, the sex of their florets, &c.

The Natural System of Botany, formed by Jussieu out of the views of Ray, Tournefort, and others, in combination with very numerous observations of his own, is the basis of what is at present understood by that name. It has, however, been much modified by succeeding systematists. The more important methods which have been promulgated, agree in adopting as their basis the fundamental divisions of Phanerogamous Vascular or Flowering, and Cryptogamous Cellular or Flowerless plants; the former being again separated into Dicotyledons the equivalents of Exogens, and Monocotyledons the equivalents of Endogens. A very full account of the various schemes which have been proposed, will be found in the introductory portion of Lindley's *Vegetable Kingdom*, to which we may refer for details.

The arrangement of De Candolle is that most commonly in use, having been familiarised by the *Prodromus* of that author, a most important book of reference for all working botanists. This arrangement includes 219 orders, under the primary divisions of Vasculares and Cellulares:—

Vasculares or *Cotyledonæ* are plants furnished with cellular tissue and vessels, and whose embryo is provided with one or more cotyledons. This includes the *Exogenæ*, or *Dicotyledonæ*, in which the vessels are arranged in concentric layers, the youngest ones being the outermost, and the embryo is furnished with opposite or verticillate cotyledons; and the *Endogenæ*, or *Monocotyledonæ*, in which the vessels are arranged in bundles, the youngest ones being in the middle of the trunk, and the embryo furnished with solitary or alternate cotyledons. The *Exogens* are divided into the *Dichlamydeæ* with a double perianth, that is, the calyx and corolla distinct; and the *Monochlamydeæ* with a simple perianth, that is, the calyx and corolla form only one envelope. The *Dichlamyds* are again divided into the *Thalamifloræ*, in which the petals are distinct, inserted on the receptacle; the *Calycifloræ*, in which the petals are free or more or less united, always perigynous or inserted on the calyx; and the *Corollifloræ*, in which the petals are united into a hypogynous corolla, or not attached to the calyx.

Cellulares or *Acotyledonæ* are plants composed of cellular tissue only, not furnished with vessels, and whose embryo is without cotyledons. This includes the *Foliaceæ*, consisting of plants which have leaf-like expansions, and known as *sexes*; and the *Aphyllæ*, consisting of plants

BOTANY

which have neither leaf-like expansions nor (as was then supposed) known sexes.

In the arrangement proposed by Lindley the number of Orders extends to 303. The main divisions consist of *Asexual* or *Flowerless plants*, which include Thallogens and Acrogens; and *Sexual* or *Flowering plants*, which include Rhizogens, Endogens, Dictyogens, Gymnogens, and Exogens.

THALLOGENS are Flowerless plants whose stems and leaves are undistinguishable. They include the following Alliances:—

Algales.—Cellular flowerless plants, nourished through their whole surface by the medium in which they vegetate; living in water or very damp places; propagated by zoospores, coloured spores, or tetraspores. Ex. *Fucacea*, or Sea-weeds.

Fungales.—Cellular flowerless plants, nourished through their thallus (spawn or mycelium); living in air; propagated by spores, colourless or brown, and sometimes enclosed in asci; destitute of green gonidia. Ex. *Hymenomyces*, or Toadstools.

Lichenales.—Cellular flowerless plants, nourished through their whole surface by the medium in which they vegetate; living in air; propagated by spores usually enclosed in asci; and always having green gonidia in their thallus. Ex. *Parnetiaceæ*, or Leaf Lichens.

ACROGENS are Flowerless plants whose stems and leaves are distinguishable. The Alliances are—

Muscales.—Cellular (or vascular); spore-cases immersed or calyptrate (i. e. either plunged in the substance of the frond, or enclosed within a hood). Ex. *Bryaceæ*, or Urn Mosses.

Lycopodales.—Vascular; spore-cases axillary or radical, one or many celled; spores of two sorts. Ex. *Lycopodiaceæ*, or Club Mosses.

Filicales.—Vascular; spore-cases marginal or dorsal, one-celled, usually surrounded by an elastic ring; spores of but one sort. Ex. *Polypodiaceæ*, or Ferns.

RHIZOGENS are Flowering plants with fructification springing from a thallus. The Orders are *Balanophoraceæ*, *Cytinaceæ*, and *Rafflesiaceæ*.

ENDOGENS are Flowering plants with fructifications springing from a stem; the wood of the stem youngest in the centre; the cotyledon single; and the leaves parallel-veined, permanent. The Alliances are:—

Glumales.—Flowers glumaceous, that is to say, composed of bracts not collected in true whorls, but consisting of imbricated, colourless, or herbaceous scales. Ex. *Graminaceæ*, or Grasses.

Arales.—Flowers naked, or consisting of scales, declinuous, two or three together, or numerous and then sessile on a simple naked spadix; embryo axile; albumen mealy or fleshy, sometimes wanting. Ex. *Araceæ*, or Arads.

Palmates.—Flowers with both calyx and corolla, declinuous (in some cases hermaphrodite), sessile on a branched scaly spadix; embryo

vague, solid; albumen horny or fleshy. Ex. *Palmaceæ*, or Palms.

Hydrales.—Flowers perfect or imperfect, declinuous or sometimes hermaphrodite, usually scattered; embryo axile, without albumen; aquatic. Ex. *Naiadaceæ*, or Naiads.

Narcissales.—Flowers with a superior calyx and corolla, hermaphrodite, symmetrical; stamens 3 or 6 or more, all perfect; seeds with albumen. Ex. *Amaryllidaceæ*, or Amaryllids.

Anomales.—Flowers with a superior calyx and corolla, hermaphrodite, unsymmetrical; stamens 1-5, some at least of which are petaloid; seeds with albumen. Ex. *Marantiaceæ*, or Marants.

Orchidales.—Flowers with a superior calyx and corolla, hermaphrodite, unsymmetrical; stamens 1-3; seeds without albumen. Ex. *Orchidaceæ*, or Orchids.

Xyridales.—Flowers half herbaceous, with an inferior calyx and corolla, hermaphrodite; 2-3 petaloidous; albumen copious. Ex. *Comelinaceæ*, or Spiderworts.

Juncals.—Flowers with an inferior calyx and corolla, hermaphrodite, herbaceous, dry, and permanent, scarious if coloured; albumen copious. Ex. *Juncaceæ*, or Rushes.

Liliales.—Flowers with an inferior calyx and corolla, hermaphrodite, hexapetaloidous, succulent, and withering; albumen copious. Ex. *Liliaceæ*, or Lilyworts.

Alismals.—Flowers with an inferior calyx and corolla, hermaphrodite, or sometimes declinuous, 3-6 petaloidous, apocarpal; albumen none. Ex. *Alismaceæ*, or Alismads.

Dictyogens are like Endogens, except that the leaves are net-veined, deciduous. The wood of the stem, when perennial, is arranged in a circle with a central pith. The Orders are *Dioscoreaceæ*, *Smilacæ*, *Philesiaceæ*, *Trilliaceæ*, and *Roxburghiaceæ*.

Gymnogens are Flowering plants whose fructification springs from a stem the wood of which is youngest at the circumference, always concentric; the cotyledons 2 or more; and the seeds quite naked. The Orders are *Cycadaceæ*, *Pinaceæ*, *Taxaceæ*, and *Gnetaceæ*.

Exogens are like Gymnogens, except that the seeds are enclosed in seed-vessels. They are distributed into four sub-classes:—

(i.) **Declinuous Exogens.**—Flowers declinuous, without any customary tendency to become hermaphrodite. The Alliances are—

Amentales.—Flowers in catkins, achlamydeous or monochlamydeous; carpels superior; embryo small, with little or no albumen. Ex. *Salicaceæ*, or Willowworts.

Urticales.—Flowers scattered, monochlamydeous; carpel single, superior; embryo large, lying in a small quantity of albumen. Ex. *Urticaceæ*, or Nettleworts.

Euphorbiales.—Flowers scattered, monochlamydeous; carpels consolidated, superior; placentæ axile; embryo surrounded by abundant albumen, which is occasionally absent. Ex. *Euphorbiaceæ*, or Spurgeworts.

Quernales.—Flowers in catkins, monochlamydeous; carpels inferior; embryo amygdaloid, without albumen. Ex. *Corylaceæ*, or Mustworts.

Garryales.—Flowers monochlamydeous, sometimes amentaceous; carpels inferior; embryo minute, in a large quantity of albumen. Ex. *Garryaceæ*, or Garryads.

Menispermaceæ.—Flowers mono-di-chlamydeous; carpels superior, disunited; embryo surrounded by abundant albumen. Ex. *Menispermaceæ*, or Menispermads.

Cucurbitales.—Flowers mono-di-chlamydeous; carpels inferior; placentæ parietal; embryo without albumen. Ex. *Cucurbitaceæ*, or Cucurbits.

Papayales.—Flowers dichlamydeous; carpels superior, consolidated; placentæ parietal; embryo surrounded by abundant albumen. Ex. *Papayaceæ*, or Papayads.

(ii.) *Hypogynous Exogens*.—Flowers hermaphrodite or polygamous; stamens entirely free from the calyx and corolla. The Alliances are:—

Violales.—Flowers mono-di-chlamydeous; placentæ parietal or sutural; embryo straight, with little or no albumen. Ex. *Violaceæ*, or Violetworts.

Cistales.—Flowers mono-di-chlamydeous; placentæ parietal or sutural; embryo curved or spiral, with little or no albumen. Ex. *Cistaceæ*, or Rock Roses.

Malvales.—Flowers mono-di-chlamydeous; placentæ axile; calyx valvate in æstivation; corolla imbricated or twisted; stamens definite or indefinite; embryo with little or no albumen. Ex. *Malvaceæ*, or Mallowworts.

Sapindales.—Flowers mono-di-chlamydeous, unsymmetrical; placentæ axile; calyx and corolla imbricated; stamens definite, rarely indefinite; embryo with little or no albumen. Ex. *Sapindaceæ*, or Soapworts.

Guttiferales.—Flowers mono-di-chlamydeous; placentæ axile; calyx imbricated; corolla imbricated or twisted; stamens indefinite, sometimes definite; embryo with little or no albumen. Ex. *Clusiaceæ*, or Guttifers.

Nymphales.—Flowers dichlamydeous; placentæ axile or sutural; stamens indefinite; embryo on the outside of a very large quantity of mealy albumen, the latter sometimes wanting. Ex. *Nymphaeaceæ*, or Waterlilies.

Ranales.—Flowers mono-di-chlamydeous; placentæ sutural or axile; stamens indefinite; embryo minute, enclosed in a large quantity of fleshy or horny albumen. Ex. *Ranunculaceæ*, or Crowfoots.

Berberales.—Flowers mono-di-chlamydeous, unsymmetrical in the ovary; placentæ sutural, parietal, or axile; stamens definite; embryo enclosed in a large quantity of fleshy albumen. Ex. *Berberidaceæ*, or Berberids.

Ericales.—Flowers dichlamydeous, symmetrical in the ovary; placentæ axile; stamens definite; embryo enclosed in a large quantity of fleshy albumen; stamens occasionally adherent to the corolla. Ex. *Ericaceæ*, or Heathworts.

Rutales.—Flowers mono-di-chlamydeous, symmetrical, occasionally declinuous; placentæ axile; calyx and corolla imbricated, if present; stamens definite; embryo with little or no albumen. Ex. *Rutaceæ*, or Rueworts.

Geraniales.—Flowers mono-di-chlamydeous, symmetrical; placentæ axile; calyx imbricated; corolla twisted; stamens definite; embryo with little or no albumen. Ex. *Geraniaceæ*, or Cranesbills.

Silinales.—Flowers mono-di-chlamydeous; placentæ free, central; embryo external, curved round a little mealy albumen; carpels more than one, completely combined into a compound fruit. (Some are slightly perigynous, others declinuous.) Ex. *Caryophyllaceæ*, or Silenads.

Chenopodials.—Flowers monochlamydeous; placentæ free, central; embryo external, either curved round or applied to the surface of a little mealy or horny albumen; carpels solitary, or, if more than one, distinct. (Some slightly perigynous, others declinuous.) Ex. *Chenopodiaceæ*, or Chenopods.

Piperales.—Flowers achlamydeous; embryo minute, on the outside of a large quantity of mealy albumen. (Occasionally declinuous.) Ex. *Piperaceæ*, or Pepperworts.

(iii.) *Perigynous Exogens*.—Flowers hermaphrodite or polygamous; stamens growing to the side of either the calyx or the corolla; ovary superior, or nearly so. The Alliances are:—

Ficoidales.—Flowers mono-di-chlamydeous; placentæ central or axile; corolla, if present, polypetalous; embryo external, and curved round a small quantity of mealy albumen. Ex. *Miscobryaceæ*, or Ficoids.

Daphnales.—Flowers monochlamydeous; carpel solitary; embryo amygdaloid, without albumen. Ex. *Thymelaceæ*, or Daphnads.

Rosales.—Flowers mono-di-chlamydeous; carpels more or less distinct; placentæ sutural; seeds definite; corolla, if present, polypetalous; embryo amygdaloid, with little or no albumen. Ex. *Rosaceæ*, or Roseworts.

Saxifragales.—Flowers mono-di-chlamydeous; carpels consolidated; placentæ sutural or axile; seeds indefinite; corolla, if present, polypetalous; embryo taper, with a long radicle, and little or no albumen. Ex. *Saxifragaceæ*, or Saxifrages.

Rhamnals.—Flowers mono-di-chlamydeous; carpels consolidated; placentæ axile; fruit capsular, berried, or drupaceous; seeds definite; embryo amygdaloid, with little or no albumen. Ex. *Rhamnaceæ*, or Rhamniads.

Gentianales.—Flowers dichlamydeous, monopetalous; placentæ axile or parietal; embryo minute, or with the cotyledons much smaller than the radicle, lying in a large quantity of albumen. Ex. *Gentianaceæ*, or Gentianworts.

Solanals.—Flowers dichlamydeous, monopetalous, symmetrical; placentæ axile; fruit 2-3 celled; embryo large, lying in a small quantity of albumen. (Occasionally achlamydeous, or polypetalous.) Ex. *Solanaceæ*, or Nightshades.

Cortusals.—Flowers dichlamydeous, monopetalous, symmetrical; placentæ free, central;

embryo lying among a large quantity of albumen (Occasionally monochlamydeous, or poly-petalous.) Ex. *Primulaceæ*, or Primworts.

Echiales.—Flowers dichlamydeous, monopetalous, symmetrical or unsymmetrical; fruit nucamentaceous, consisting of several one-seeded nuts, or of clusters of them separate or separable; embryo large, with little or no albumen. (Very rarely hypogynous.) Ex. *Boraginaceæ*, or Borageworts.

Bignoniales.—Flowers dichlamydeous, monopetalous, unsymmetrical; fruit capsular or berried, with its carpels quite consolidated; placentæ axile, or parietal, or free central embryo with little or no albumen. Ex. *Bignoniaceæ*, or Bignoniads.

(iv.) *Epigynous Exogens*.—Flowers hermaphrodite or polygamous; stamens growing to the side of either the calyx or corolla; ovary inferior or nearly so. The Alliances are:

Campanales.—Flowers dichlamydeous, monopetalous; embryo with little or no albumen. Ex. *Campanulaceæ*, or Bellworts, and *Asteraceæ*, or Composites.

Myrtales.—Flowers dichlamydeous, polypetalous; placentæ axile; embryo with little or no albumen. (Occasionally monochlamydeous.) Ex. *Myrtaceæ*, or Myrtleblooms.

Cactales.—Flowers dichlamydeous, polypetalous; placentæ parietal; embryo with little or no albumen. Ex. *Cactaceæ*, or Indian Figs.

Grossales.—Flowers dichlamydeous, polypetalous; seeds numerous, minute; embryo small, lying in a large quantity of albumen. Ex. *Grossulariaceæ*, or Currantworts.

Cinchonales.—Flowers dichlamydeous, monopetalous; embryo minute, lying in a large quantity of albumen. Ex. *Cinchonaceæ*, or Cinchonads.

Umbellales.—Flowers dichlamydeous, polypetalous; seeds solitary, large; embryo small, lying in a large quantity of albumen. Ex. *Apiaceæ*, or Umbellifers.

Asarales.—Flowers monochlamydeous; embryo small, lying in a large quantity of albumen. Ex. *Aristolochiaceæ*, or Birthworts.

For further details of the Structure and Classification of plants, the reader may consult with advantage Lindley's *Introduction to Botany*, *Elements of Botany*, and *Vegetable Kingdom*, and the works of Balfour, Henfrey, Henslow, Oliver, and Asa Gray.

Botany Bay Gum. A gum resin produced from the *Xanthorrhæa hastilis* (alias, *resinifera*) of New Holland.

Botryarians, Botrylaris (Gr. *Botrys*, a bunch of grapes). In Zoology, a family of singular compound Tunicaries or Ascidians, in which several distinct individuals are arranged in a circle round a central aperture common to the rectum of each, while the mouths are distinct and placed at the circumference.

Botryogene. A hydrated sulphate of iron, composed of 19 per cent. of sulphate of protoxide of iron, 48·3 sulphate of peroxide of iron, and 32·7 water. It is found in the great copper-mine of Fahlun in Sweden, in

small crystals of a deep hyacinth-red colour, passing into ochre-yellow in massive varieties, and is often aggregated into reniform and botryoidal shapes, consisting of globules with a crystalline surface like that of a bunch of grapes.

Botryoidal (Gr. *Botrys*, and *eidōs*, likeness). In Botany, when a part (the inflorescence, for example) is clustered like a bunch of grapes. The term is used in Mineralogy when the surface of a mineral consists of a group of sections of clustered globular prominences. When the prominences are larger, and less globular, the appearance is expressed by the term *mammillated* or *mammillary*. The shape is frequently assumed by Chalcedony and Hematite, and certain ores of copper and manganese, are familiar examples of these modes of aggregation.

Botryolite (Gr. *Botrys*, and *lithos*, stone). A kind of Datholite occurring in mammillary concretions with a delicate fibrous texture, in the veins of magnetic iron-ore, at Arendal in Norway. It is a silicious borate of lime.

Botrytis (Gr. *Botrys*). A genus of microscopic Fungi, or moulds, chiefly remarkable as containing the parasitic species of fungus which plays so important a part in the development of the potato disease. This species is best known as *B. infestans*, though it is sometimes referred to the genus *Peronospora*. The fungous disease in silkworms called muscardine is attributable to another species, *B. Bassiana*. The nomenclature of these minute fungi is so fluctuating, owing to increased facility for studying their organisation, that the species above referred to may not improbably soon bear other names.

Bottom Heat. A term applied in Horticulture to the temperature communicated to certain soils either by fermenting and decomposing substances placed underneath them, for which purpose leaves, fresh dung, and the refuse bark of the tan-yard are often used; or by means of flues or hot-water apparatus. The system is applied to the cultivation of pine-apples, grapes, melons, cucumbers, and other plants grown in hothouses, pits, or frames. It is one of the most important agents in the artificial cultivation of tender plants of whatever kind, whether flower-bearing or fruit-bearing.

Bottom Rail. In Architecture, a term used for denoting the lowest horizontal rail of a framed door.

Bottom of a Ship. Is strictly that portion of the vessel which is under water; but in a more general sense it stands for the ship itself, as in the expression, 'A trade in foreign bottoms.'

Bottomry. In Commercial Law, is in effect a mortgage of a ship, being an agreement entered into by an owner or his agent, whereby, in consideration of a sum of money advanced for the use of the ship, the borrower undertakes to repay the same, with interest, if he ship terminate her voyage successfully:

BOUCHE OF A GUN

and binds or hypothecates the ship for the performance of the contract. The instrument by which this contract is effected is sometimes in the shape of a deed poll, and sometimes in that of a bond. On bottomry contracts the lender runs the risk of the voyage, and in consideration of the risk the rate of interest is usually high. The master has authority to hypothecate a ship or its freight [RESPONDENTIA] at a foreign port, in case of necessity, for the purposes of the voyage. In such case, if the loan be not repaid within the time prescribed, the agent of the lenders applies to the Court of Admiralty, with certain affidavits, and procures authority to arrest the ship, which may be sold, if necessary, under the authority of the court. Where several loans of this description have been made on the same voyage, the last lender is entitled to priority of payment out of the proceeds of the sale.

Bouche of a Gun. A piece of copper containing the vent or orifice through which the charge of a gun is ignited.

Boudoir (Fr.) In Architecture, the word boudoir is applied to a small room or cabinet, usually near the bed-chamber or dressing-room, but also occasionally near the drawing or reception rooms, for the private retirement of the master or mistress of the house.

Bouget (properly Boujet). In Heraldry, an ancient water-bucket, frequently borne in shields of arms.

Bougie (Fr.) A slender flexible tube, intended for introduction into the urethra, oesophagus, or rectum, when those passages are obstructed by stricture or other disease.

Boulangerite. A sulphantimonite of lead and antimony composed of 58 per cent. of lead, 24 antimony, and 18 sulphur. It generally occurs in plumose masses, which exhibit a crystalline structure when fractured; sometimes granular and compact. The colour is bluish lead-grey, often coloured with yellow spots caused by oxidation; and the lustre is metallic. It is found abundantly in France at Molières (Dépt. du Gard); also massive, acicular and fibrous at Bottino in Tuscany; in Lapland, &c. Named after M. Boulanger, mining engineer.

Boulder. Boulders in Geological language are fragments of rock rounded by attrition lying on or within the surface, and not derived from the rocks on which they lie.

In many cases these boulders have been transported hundreds of miles, and sometimes only a few yards; but they have always been moved from their original position by the action of water or ice. A boulder of granite 42 ft. long, 27 ft. broad and 21 ft. high has been used as a natural plinth of the statue of Peter the Great at St. Petersburg. Small boulders of foreign rock have occasionally been found in the chalk and other aqueous rocks.

Boulder Clay. A deposit, often very extensive, consisting of boulders of various size, angular or rounded, mixed with sand and clay, and lying generally in an unstratified position

BOUNTY

unconformably to the other rocks on the earth's surface. Although there is no reason why such a deposit should not have been made at any geological period, boulder clay seems to be of definite age in the northern hemisphere, or at least is limited to a certain geological period. It is one of those deposits spoken of collectively as *Drift*, and would seem to be due to a time not very distant, when glaciers covered much of north European land, and icebergs drifted and were stranded over the shoals that have since been raised to form the land. [GLACIAL DRIFT.]

Boulé (Gr. a council). By this name the Athenian senate was designated, the constitution of which was as follows: When the people were divided into four tribes, each of these, according to the regulation of Solon, elected 100 representatives, thus making in all a deliberative body of 400 members. But when Cleisthenes increased the number of tribes to ten, the complement of the senate was raised to 500, fifty of which were sent by each tribe; when the tribes were finally increased to twelve, 100 more senators were added. All free-born Athenian citizens above thirty years of age were eligible to this office; but according to law they were obliged to undergo a strict examination of their characters and morals. The senate was originally instituted by Solon to be a check on the assembly of the whole people (*ekklesia*), before which, according to the Athenian constitution, no measures were allowed to be brought until they had been approved by the senate. [PRYTANES.]

Boule (Fr.) or Boule-work. A kind of marquetry or inlaid work in woods, gilt-metal, or tortoise-shell, so called from the name of a French cabinetmaker or ébéniste, who greatly distinguished himself for ornamental work of this kind, in the reign of Louis XIV. There were two French ébénistes, father and son, of this name, which has been lately corrupted into Buhl.

Boules de Wancy. Small balls composed of potassio-pertartrate of iron: the *globuli martiales* of old pharmacy.

Boulton. In Architecture, the name given to a moulding whose section is nearly a quadrant of a circle, whose diameter being horizontal, the centre is convex with respect to a vertical to such diameter. It is more usually called the ovolo, or the quarter round.

Bounty (Fr. bonté, Lat. bonitas). The money given to a recruit for the army after his attestation and final approval. The amount of bounty in our service has varied very much from time to time according to the difficulty of obtaining recruits. A recruit now receives 1*l.* bounty, and a free kit. In America, during the present war, the bounty to recruits has risen as high as 500 dollars or about 100*l.* The system of large bounties is a great temptation to soldiers to desert after receiving them, and enlist again in other regiments, and most thinking men consider a higher rate of pay would have a better effect than bounty.

BOUNTY

BOUNTY. In Commerce and the Arts, a premium paid by government to the producers, exporters, or importers of certain articles, or to those who employ ships in certain trades, when the profits resulting from these respective branches of industry are alleged to be insufficient. Bounties on production are usually given with the view of encouraging the establishment of some new branch of industry, or of fostering and extending a branch that is believed to be of paramount importance. Bounties on *exportation* and *importation* are granted to the exporters of certain British commodities on their taking oath, or in some cases giving bond, not to re-land the same in England. Public opinion was formerly very divided as to the advantage of granting bounties; but at present the impolicy of such a practice appears to be almost universally admitted. For details upon this subject, see *McCulloch's Commercial Dictionary*.

Bounty, Queen Anne's. The produce of the first fruits and tenths due to the crown [FIRST FRUITS], which were made over by Queen Anne to a corporation established in the year 1704 for the purpose of augmenting poor livings under 50*l.* a year.

Bourdon (Fr. *a staff*). In Music, the drone or bass in some musical instruments, and the pipe or string that plays it. The bass pipe in the bagpipe is so called. Hence, that part of a song that is repeated at the end of every stanza is called the burden of it.

Bourgeois (Fr.). In Printing, a kind of type one size larger than that used in this work. [TYPE.]

Bournonite. A triple sulphide of copper, lead, and antimony, composed of 41·8 per cent. of lead, 26 antimony, 12·8 copper, and 19·4 sulphur. It occurs in crystals (which are often cruciform), massive and disseminated; of a steel-grey colour, inclining to dull lead-grey with a tinge of black, and is opaque with a brilliant metallic lustre.

Bournonite was first found at Huel Boys, in the parish of St. Endellion [ENDELLIONITE] in Cornwall, and is so plentiful in the mines of that neighbourhood as to furnish an ore of copper: fine, and sometimes compound crystals (called *wheel-ore*), are, also, met with at Herodsfoot Mine near Liskeard. Crystals occasionally more than an inch in diameter occur in the mines of Neudorf in the Harz. Other localities are Kapnik in Transylvania, Servoz in Piedmont, Saxony, Bohemia, Hungary, Spain, &c.

Some of the Freiberg varieties of this ore contain about 0·12 per cent. of silver.

Named in honour of the count de Bournon, by whom it was first described and called Endellione.

Boustrophedon (Gr. from *βοῦς*, an ox, and *στρέφω*, I turn). A word descriptive of a mode of writing common among the early Greeks until nearly the middle of the fifth century before Christ: viz. in alternate lines from right to left and from left to right, as fields are

BOX

ploughed in furrows having an alternate direction, whence the derivation. [ALPHABET.]

Bout. In Agriculture, one turn or course of a plough in ploughing a ridge.

Bovate. [OXGANG; PLOUGHLAND.]

Bovey Coal. The lignites found at Bovey Tracey in Devonshire (not far from Exeter) are called by this name. They are of the tertiary period, and have occasionally been used as fuel, chiefly for burning pottery and for brick and tile making. They burn badly, with much smoke and disagreeable odour, and are of little use.

Bow. An ancient weapon of offence, made of wood, horn, steel, or some other elastic substance, by which arrows are thrown. The force with which the arrow is propelled is proportioned to that with which the bow is bent, and to the quickness with which it recovers its former position. [ARCHER.]

Bow. In Music, the instrument by which the strings of the violin tribe of instruments are set in vibration.

Bows. The two sides of the fore extremity of a vessel, as the starboard and larboard bows.

Bow-string Bridge. A peculiar form of plate-iron bridge, in which the strength is obtained by means of a truss in the form of a reversed bow-string, standing as it were upon the string; the strength of this form of bridge depends upon the resistance to tension of the bow being increased by the resistance of the chord line, which is usually made of chains, or bars, like those of a suspension bridge. The best examples near London are the bridges upon the Blackwall Extension line, where they have been executed of 110 feet span, in some cases.

Bow-window. [BAY.]

Bowdichia (named after Mr. T. E. Bowdich). A genus of South American *Leguminosæ*, forming large trees with pinnated leaves, and terminal flower-panicles. The astringent Alcornoco Bark is obtained from *B. virgiloides*.

Bowenite. A bright apple-green variety of Serpentine, which is found at Smithfield, in Rhode Island, North America. It is named after Bowen, by whom it was first described (as a kind of Nephrite).

Bower-anchor. A name given to the smaller anchors, carried in the bows of a ship.

Bowline. A rope from near the middle of the weather edge or leech of a sail, leading forward. Its use is to keep the leech forward, that the wind may get at the after-side of the sail when very oblique to its direction.

Bowsprit or Boltsprit. In Naval Architecture, a large spar or mast, projecting from the bows, to which, in large vessels, are secured the forestays. It supports the jib and flying jib booms.

Box (Gr. *βύξ*, Lat. *buxus*). The hard compact wood of *Buxus sempervirens*, much used by wood engravers, and for the turner's purposes. This evergreen bush or small tree of the Euphorbiaceous order is found all over Europe, even upon the chalk hills of England; but acquires its largest dimensions in the south. It is from Turkey that the principal

BOX DRAIN

part of the wood is imported into England, formerly at a duty of 5*l.* a ton: whether or not all this is really furnished by *Buxus sempervirens* is not known. It is not improbable that *Buxus balcanica*, a larger species, somewhat tender in this country, may furnish a part at least of that which comes from the Mediterranean. It is said that the wood of this species is coarser and of a brighter yellow than that of the common species. The Box plant is best known by its use in gardens as an edging for borders; the kind so employed is a dwarf variety of *Buxus sempervirens*.

Box Drain. An underground drain, regularly built, with upright sides and a flat stone or brick cover, so that the transverse section resembles a box, is so called to distinguish it from the other forms of drains.

Box Girder. A form of girder resembling a box, made out of boiler plate, fastened together by means of angle irons, which are riveted respectively to the top and bottom plates. For

city, and the power of resisting violent impact, is far greater in this class of girders than in the old form of cast iron. Mr. Fairbairn, their inventor, has given the following formula for calculating their resistance: $W = \frac{ade}{l}$, in which

W = the breaking weight applied in the centre; a = the area of the bottom flange; d = the depth of the beam in inches; e = a coefficient = 75 for wrought iron; and l = the span in inches.

Box Bauling. In Seamanship, is bringing a ship when close-hauled round upon the other tack, when she refuses to tack and there is not room to wear. By throwing the head-sails aback she gets sternway: the helm thereupon being put a-lee, the ship's head is rapidly off from the wind, which she soon brings about, and then speedily rounded to with but little loss of ground. This term is now obsolete.

Box the Compass. Repeating the thirty-two points of the compass in order.

Boxing On. Throwing the head-sails aback to force the ship's head rapidly off the wind.

Boxing.

Boy-bishop. During the middle ages, the custom grew up of allowing the choristers of cathedrals to choose yearly one of their number to act the part of a bishop. The practice was permitted probably from the same motives which suffered the numeraries of the Abbey of Unreason (a graphogolical school which may be found in Sir Walter Scott's romance of *The Monastery*). If the boy-bishop died within his short period of office, he was buried in his episcopal robes. A tomb with the effigy of a boy so clothed may be seen in Salisbury Cathedral.

Boyle's Ruming Liquor. Disulphuric ammonium. It is a deep-yellow fetid liquid.

Boyle's Law. The volume of a gas is inversely as the pressure. For example, if we double the pressure upon a gas its bulk will be

BRACHISTOCHROME

reduced to one-half. If the pressure be trebled the volume will be one-third, and so on.

Braccate (Lat. *braccatus*, from *bracca*, *brecches*). In Ornithology, when the feet are concealed by long feathers descending from the tibiae.

Brace (Fr. *bras*, *the arm*). In Architecture, an inclined piece of timber used in trussed partitions, and roofs, in order to form a triangle by which the assemblage of pieces composing the frame is stiffened. When braces are used in roofs and partitions, they should as far as possible be introduced in pairs, and be framed in opposite directions to one another.

BRACE. In Music, the line or bracket at the beginning of each set of staves which ties them together in a vertical direction.

BRACE. In Seamanship, a rope fastened to or rove through a block at the yardarm, for the purpose of trimming the yards horizontally.

Brachelytra (Gr. *Braxys*, *short*; *Elavpon*, *sheath*). The name of an extensive group of Coleopterous insects, including all such as have the elytra so short as not to exceed one-third the length of the abdomen. To this section belongs the well-known species called the devil's coach-horse (*Staphylinus olens*).

Brachial (Lat. *brachium*, *the arm*). Belonging to the arm; as brachial nerves, vessels, &c.

Brachinus. A genus of Coleopterous insects, now the type of a family (*Brachinidae*), including those singular beetles which from their defensive anal explosions are termed 'bombardiers.' Of these there are five British species, the best known of which is the *Brachinus crepitans* of Linnæus.

Brachiomis. The name given by Müller to a genus of Rotiferous Infusorial Animals, since subdivided into many distinct genera.

Brachipoda, Brachyopoda (Gr. *Braxia*, *an arm*; *pous*, *a foot*). A class of bivalve Mollusca characterised by having the mantle pigmented so as to be servicable for respiration, and by having two long, fleshy, elongated apical arms, or labiate processes, whence Cuvier conceived the name, which in his system designates distinct classes of Animals. The following is a list of the orders of the class *Brachipoda*: *Tremulacidae*, *Spiridae*, *Rhynchonellidae*, *Cypridae*, *Prothoidae*, *Antidae*, *Diactinidae*, *Limuloidae*.

Brachistochrone (Gr. *Braxistos*, *shortest*; *chronos*, *time*). The plane curve down which a material particle must fall in order to pass in the shortest possible time from the upper to the lower of two given points in the same vertical line. It is a cycloid.

The problem of the *Brachistochrone* was first treated one in the history of mathematics proposed by John Bernoulli, in the *Leipzig Acta Eruditorum* for June 1696, and solved by Newton, James Bernoulli (John's brother), and the marquis de l'Hôpital. The consideration of this problem led James Bernoulli to others of kindred character, relating to isoperimetrical figures, the adequate treatment of which required a different calculus from any then

BRACHIUM

known. This calculus, the calculus of variations, was in due time developed by Euler, Lagrange and others, and constitutes one of the most important branches of the higher mathematics. It is by this calculus that the problem of the *brachistochrone* is now always solved.

Brachium (Lat. *arm*). In Mammalogy, this term is restricted to the second segment of the anterior extremity. In Entomology, it signifies the first pair of legs of Hexapoda, the direction of which is usually towards the head.

Brachycatalectic (Gr. *βραχύς*, *short*, and *καταληκτικός*, *deficient*). A verse wanting two syllables to complete its length (in Greek and Latin poetry).

Brachygraphy (Gr. *βραχύς*, *short*, and *γράφω*, *I write*). The art of writing by abbreviations. [TACHYGRAPHY.] The notes Tiro-nians, among the Romans, were a species of shorthand invented by one Tiro, a freedman of Cicero.

Brachycephalic (Gr. *βραχύς*, *short*, and *κεφαλή*, *head*). This term is applied by Prof. Retzius to all skulls whose transverse diameter is more than $\frac{1}{2}$ of their longitudinal diameter. It is supposed that a brachycephalic race of men existed in Europe before that continent was inhabited by the Celtic tribes. The classification of human skulls into brachy- and dolicho-kephalic is merely artificial, and does not denote a difference of race. Brachy- and dolicho-kephalic heads are to be found in nearly all the races of man. The majority of brachycephalic skulls are to be found in the Turanian or 'Mongol' nations. [DOLICHO-KEPHALIC; MESATIKEPHALIC.]

Brachypteros (Gr. *βραχύς*, *short*; *πτερά*, *wing*). In Ornithology, when the folded wings of a bird do not reach to the base of the tail.

Brachyura (Gr. *βραχύς*, *short*; *οὐρά*, *a tail*). A tribe of Decapodous Crustacea, in which the tail or post-abdomen is short, and folded beneath the trunk; commonly called *crabs*.

Bracken. [PHEASANT.]

Bracket (Fr. *brague*, *a mortise*; Latham). In Architecture, the word bracket is often employed to signify an ornament in the shape of a console standing isolated upon the face of a wall; it is used for this purpose both in classical and mediæval architecture, with the differences attending each course of treatment.

Bracklesham Beds. The name given in and to the part of the Eocene deposits lying the 'London clay' series. The Bracklesham beds appear to be the equivalent of the CALCAREOUS GRASSES. They are well seen at Alum Bay in the Isle of Wight, and on the opposite Hampshire coast, attaining in some places a thickness of 500 feet.

The Bracklesham beds are also the equivalents, in time, of the deposits of the Brussels basin and a part of the great NUMMULITIC FORMATION. Most of the foraminiferous deposits of that formation are, however, somewhat older.

BRAHMA

The Bracklesham beds are generally fossiliferous, and contain large series of characteristic fossils, careful lists of which have been published by Mr. Prestwich in the *Quarterly Journal of the Geological Society*, vol. x. (1854) p. 450.

Bracon. A Fabrician genus of Hymenopterous insects of the parasitic tribe of Pupivorous Ichneumons: it is now the type of a family (*Braconida*), distinguished from the true Ichneumons by having the maxillary palps five-jointed, and the labial ones either three or four jointed, and by wanting the internal discoidal cell of the upper wings. The genera of this family are *Bracon* proper; *Aphidius*, the species of which prey upon the plant-lice; *Stephanus*, *Calinius*, *Spathius*, *Perilitus*, *Hybrion*, *Leophron*, *Agathis*, *Microdus*, *Hormius*, *Ichneutes*, *Microgaster*, and *Blaesus*.

Bract (Lat. *bractea*, *a thin plate or leaf*). An altered leaf, which is placed at the base of a flower on the outside of the calyx. It is the first attempt made by the common leaves to change into the floral organs. In general the bract is small and inconspicuous, but it occasionally acquires a considerable size and a brilliant colour, as in the Brazilian pine-apple, and more especially *Poinsettia pulcherrima*, and in the various kinds of *Arum*, in which it constitutes the large enveloping leaf, called spathe, in which the spadix of those extraordinary plants is enveloped. This word forms the adjectives *bractescent*, assuming the appearance of a bract; *bracteal*, furnished with bracts; *bracteolate*, having little bracts. A *cupule* is a collection of bracts united into a cup; an *involucre* denotes the same organs arranged in a whorl. The flowers of grasses and cyperaceous plants consist of nothing but little bracts called *pales* and *glumes*.

Bradawl. A small tool used by Joiners for the purpose of boring wood: it is sometimes used as a screw-driver for small screws.

Bradford Clay. The name given to the middle member of the upper division of the Lower Oolite, as developed in the West of England. It nearly corresponds in age with the limestones of the Great Oolite, but is generally a pale greyish clay with little calcareous matter, though enclosing bands of impure limestone. It is nowhere more than sixty feet thick, and is local; but it is remarkable for the abundance of a peculiar fossil, the *Apocynites*. There are one or two species of *Terebratula* also characteristic of this deposit. The Bradford clay often passes insensibly either into the overlying or underlying beds.

Bradyoda, **Bradyoda** (Gr. *βραχύς*, *short*; *πούς*, *foot*). A family of Macrognathus or Edentate Mammals, including the two-toed and three-toed sloths.

Bragite. A mineral of doubtful identity, found at Helbo in Norway. It is a columbate of yttria, &c., and is probably identical with Tyrite.

Brahma (Hin.). The name of a divinity in the Hindu Mythology. As we learn from the Sanscrit lexicologists, the epithets applied to

this divinity are very numerous: some of the most usual being, '*Svayambhu*, the self-existent; '*Parameshti*, who abides in the most exalted places; '*Pitamaha*, the great father. '*Prajapati*, the lord of creatures; '*Lokesa*, the ruler of the world,' &c. '*Brahm*, the highest divinity of the Hindus, to whose name so deep reverence is attached that it is considered criminal to pronounce it, is said to have given birth to Brahma, Vishnu, and Siva simultaneously; and to have allotted to the first the province of creating, to the second that of preserving, and to the third that of destroying. Accordingly, ever since the creation of the world Brahma has had little or nothing to do, and it will not be till the tenth avatar or incarnation that his services will be put in requisition, when this world is to undergo total annihilation. Meanwhile, however, the other deities, Vishnu and Siva, are constantly engaged in their respective duties of preservation and destruction; and the Hindus lavish all their adoration upon those divinities from whom they expect to derive immediate advantage. Brahma is usually represented with four heads and four hands, either reclining upon a lotus tree (the emblem of creation among the Hindus) or riding upon a swan.

Brahmans or Brahmins. The first or highest of the four castes of Hindus, said to have proceeded from the mouth of Brahm (the seat of wisdom). They form the learned or sacerdotal class; and its members have maintained a more extensive sway than the priests of any other nation. Their chief privileges consist in reading the Veda or sacred volume, in instituting sacrifices, in imparting religious instruction, in asking alms, and in exemption from capital punishment. The whole life of the Brahmans is devoted to the study of the sacred writings, and is divided into four periods. The first begins at the age of seven, when the duty of the novice consists in learning to read and write, and studying in the Veda. In the second stage of a Brahman's life he is allowed to marry, and to engage in commercial speculations. In the third his religious duties become more numerous, and must be rigidly performed. But in the fourth period, the Brahman is admitted to personal communication with the Deity; and this stage is reckoned so preeminently holy, that in a single generation it imparts a greater stock of religious importance than is attainable by any other means in a thousand years. The importance of the Brahmans dates from a time later than that of the early Vedic hymns, in which Brahma himself is not known as a god, and the Brahman appears as one among a number of priests in no way his inferiors. (Prof. H. H. Wilson, in *Edinburgh Review*, No. 228, p. 381 &c.) After the promulgation of the Code of Menu, the Brahmans gradually established their supremacy. Of ancient Brahmanical science the principal remains are their astronomical and trigonometrical methods, both of which have given rise to frequent and learned discussion. Among the

modern Brahmans we look in vain for the deep learning that characterised the ancient members of this order: for, with the exception of metaphysical disquisitions, which have always been a favourite study among them, the learning of the present race of Brahmans is exceedingly meagre. Nor is it merely in point of learning that the modern Brahmans have degenerated from their ancestors. Their morals are woefully deteriorated; and while they are the sole depositaries and ministers of a religion which in point of purity and sublimity of doctrine yields only to the Christian, their conduct is characterised by the most vile and licentious practices; a spirit of avarice, falsehood, and revenge is everywhere visible; and in many cases superstition and fanaticism have been exchanged for infidelity and atheism. (Mill's *British India*; *Asiatic Researches*, passim; Coleman's *Hindoo Mythology*; Sir William Jones's *History*; Max Müller's *History of Sanskrit Literature*.)

Brails. On Shipboard, are small ropes employed in gathering up to a yard the bottom and skirts of its sail, preparatory to furling. They lessen the trouble and danger of furling sails, and allow of sail being rapidly reduced by hauling the brails either from the deck or top. When the brails are hauled taut, the sail is said to be 'brailed up.'

Brain (A.-Sax. *brægen*). The chemical examination of the brain of animals was first undertaken by Vauquelin, who found in the human brain 80 water, 7 albumen, 4.53 white fatty matter, 0.70 red fatty matter, 1.12 osmazome, 1.5 phosphorus; acids, salts, and sulphur, 5.15. An elaborate dissertation upon the composition of brain has more lately been published by M. Couerbe (*Annales de Chim. et Phys.* lvi. 160). He finds a large proportion of *cholesterine* in it: and asserts, as the result of repeated examinations, that the proportion of phosphorus in the brain of persons of sound intellect is from 2 to 2.5 per cent.: in the brain of maniacs it is from 3 to 4.5, and in that of idiots only from 1 to 1.5 per cent.

BRAIN, HUMAN, ANATOMY OF. The brain, or the general mass of nervous matter which occupies the cavity of the skull, constitutes about one thirty-fifth of the weight of the body; it is divided by anatomists into the *cerebrum*, which occupies the whole of the superior part of the cavity of the cranium; the *cerebellum*, which occupies the lower back part; and the *medulla oblongata*, which is the smallest portion, lying at the base of the cranium, beneath the cerebrum and cerebellum, and passing out of the great occipital foramen becomes as it were the origin of the spinal marrow. The brain is covered by three membranes, two of which are termed *matres*, from the old idea of their giving rise to all the other membranes of the body. The external membrane, more firm than the others, is termed *dura mater*: it is very dense and fibrous, and adheres everywhere to the inner surface of the cranium, to which it is connected by its vessels; its inner surface is

BRAIN

smooth, and it sends off several folds, or *processes*, as they are called, which descend between certain portions of the brain. Of these the principal is the superior longitudinal process, or *falx cerebri*, which descends from the fore to the back part of the skull between the hemispheres of the brain; from its posterior termination it sends off a layer or expansion, which extends across the back of the skull, and is called the *tentorium*, separating the cerebrum from the cerebellum; from the middle of the tentorium another membranous expansion descends between the lobes of the cerebellum, and terminates at the edge of the great occipital hole, or *foramen magnum*; this is termed the *falx cerebelli*. There are certain spaces or *sinus* formed in the layers of the dura mater, which perform the office of veins in regard to the blood returning from different parts of the brain, by which any venous pressure upon the substance of the brain is prevented.

When the dura mater is removed, a thin transparent membrane investing the surface and convolutions of the brain is brought to view, which from the delicacy of its texture has been called the *arachnoid* membrane. It is not apparently vascular, and does not pass into the depressions between the convolutions; and it is not easily separable from the third membrane, or *pia mater*, which is also extremely tender and delicate but is highly vascular, and from it the blood-vessels merge into the substance of the brain, ramifying with great minuteness upon its surface: it lines all the convolutions and cavities of the brain. On removing the upper part of the cranium, and turning aside the dura mater, the brain is seen, divided longitudinally into two ovoid hemispheres, separated, as already stated, by the *falx*. Upon the under side each hemisphere is seen to be divided into three lobes; the two anterior lobes rest upon the orbital plates of the frontal bone; the middle lobes lie upon the fossæ formed by the temporal and sphenoid bones; and the posterior lobes rest upon the tentorium. The superficial convolutions of the brain are divided by clefts, of about an inch in depth. On cutting into its substance, the exterior part of the brain appears of a different colour from the interior, and has been termed the *cineritious* or cortical substance; it is greyish brown, very soft, and exhibits no appearance of a fibrous texture. Some suppose that it is glandular, and constituted almost entirely of vessels and cellular membrane; it covers the whole of the brain, and is about the tenth of an inch in thickness. The inner substance, termed the white or medullary part of the brain, is of a firmer texture, highly vascular, and when minutely examined appears fibrous, the fibres decussating with each other, and occasionally combining to form commissures.

The *cerebellum*, when viewed from below, is of an elliptical shape, its longest diameter being from side to side, and is divided into two hemispheres separated by the *falx cerebelli*. In the centre of the upper part of the cerebellum there

is a prominence, termed the *vermiform process* and the whole surface is fissured or sulcated; the pia mater passing between the fissures and conveying vessels to the substance, whilst the arachnoid tunic is merely extended over them.

Such is an outline of the anatomy of the human brain; the details can only be fully understood by reference to illustrative plates upon a scale which would be incompatible with the plan of this work.

It has been already stated that in man the brain averages in weight 1-35th of the body; it weighs, in fact, about two pounds and a half: in quadrupeds its relative bulk is remarkably smaller; in the dog it averages 1-120th of the weight of the animal; in the horse 1-450th; in the sheep 1-750th; and in the ox 1-800th. This statement has been adduced to show the direct relation between the bulk of the brain and the quantity of mind, the above animals being ranged in the order of their docility and intelligence.

On making a vertical section of either hemisphere of the cerebellum, a central white substance becomes apparent, which ramifies in an arborescent form, and is called *arbor vitæ*; the exterior covering is grey. In front of the cerebellum is a protuberance, termed *pons Varolii* or *tuber annulare*; it is divided by a central groove into two halves, and connected with the cerebrum and cerebellum severally by two thick white chords called *crura*; the former, or *crura cerebri*, pass from the tuber forwards and outwards, under the middle part of each hemisphere, in which they are lost; and the latter, the *crura cerebelli*, are continued backwards and outwards, and terminate in either hemisphere of the cerebellum. The portion of the brain between the tuber annulare and the foramen of the occipital bone is called the *medulla oblongata*, and is continued into the spinal chord; on its anterior surface are four contiguous projections; the two interior are called *corpora pyramidalia*, and the two exterior *corpora olivaria*. On carefully removing the membranes which cover the medulla oblongata, and gently opening its middle groove, several white bands are seen passing obliquely from one side to the other, and mutually interwoven, and are termed the *decussating bands*.

The two sides of the brain are mutually connected by commissures or medullary bands, and those of the cerebellum by the *pons Varolii*. The principal connection of the hemispheres of the cerebrum is by a broad medullary band, called the *corpus callosum*. The occasional intervals which separate the parts of the brain are termed *ventricles*, the largest of which are the two *lateral ventricles* in the interior of each hemisphere; their figure is irregular, and they are separated by a tender layer of cerebral matter termed the *septum lucidum*; they are lined by the pia mater. The *middle* or *third ventricle* is a fissure between two convex eminences, situated at the middle and back of the lateral ventricles, and termed *thalami optici*. The *fourth ventricle*, or *ventricle of the cere-*

BRAIRD

bellum, is a cavity between the cerebrum, the tuber annulare, and the medulla oblongata.

Braird. In the Agriculture and Gardening of Scotland, the term braird is applied to the springing up of seeds, which, when they come up well, are said to have a fine braird.

Brake. In Agriculture, a large harrow.

Bran (Fr.). The husk of wheat which immediately covers the grain, and which remains in the bolting machine. It is gently laxative; an infusion of it, under the name of *bran tea*, is frequently used as a domestic remedy for coughs and hoarseness. *Calico printers* employ bran and warm water with great success to remove colouring matter from those parts of their goods which are not mordanted.

Branch Coal. A provincial term, applied, in Yorkshire, to Cannel and other kinds of coal, when the layers appear to traverse the main body of the seam, from which they differ in quality, being generally more inflammable.

The *Glô Spagod* or Branching Coal of South Wales is so called in consequence of the swelling or branching which takes place during combustion and in the process of coking. In some varieties, as in that from the Clyngwernon seam, this peculiarity is carried to such an extent as to render the coke almost as light and porous as wood-charcoal. (*History of Fossil Fuel*, p. 414.)

Branchiæ (Gr. *Ἀπρύξια*, *the gills of a fish*). The term applied to all vascular organs of an animal body which are destined to submit the circulating fluid in a state of minute subdivision, for the purpose of respiration, to the influence of air contained in water.

Branchiopoda, Branchiopoda (Gr. *Ἀπρύξια*, and *πούς*, *a foot*). An order of Crustaceans, in which the locomotive extremities fulfil the functions of gills.

Branchiostegans, Branchiostegi (Gr. *Ἀπρύξια*, and *στέγας*, *I cover*). A tribe of cartilaginous fishes, comprehending those in which the gills are free, and covered by a membrane; including the sturgeon and chimæra.

Branchite. A colourless translucent mineral hydrocarbon resembling Scheerite, from the Brown Coal of Mount Vaso, in Tuscany.

Brandisite. A variety of Clintonite, occurring in crystals lining cavities in a rock which is chiefly composed of Pyroxene, at Toal della Foja de Monzani, in the Tyrol.

Brandy (Ger. *Braunt-wein*, *burnt-wine*; the old English forms, *brandwine* and *brandy-wine*, are now obsolete). The spirituous liquor obtained by the distillation of wine. When pure it is perfectly colourless, and only acquires a pale brown or yellow tint from the cask. The deep colour of common brandy, intended to imitate that which it acquires from great age in the cask, is generally given by the addition of burnt sugar. The average proportion of alcohol in brandy varies from 48 to 54 per cent. The best brandy is made in France, the preference being generally given to that shipped from Cognac. The duties on brandy and other foreign spirits, which had been re-

BRASSAGE

duced by Sir R. Peel from 22s. 6d. a gallon to 15s., were further reduced in 1860 to 8s. 6d., the amount levied on English spirits.

Brash. A local name, but one sufficiently common in English geology. It is meant to designate a mass of broken and angular fragments derived from a subjacent rock, generally limestone. The *Cornbrash* is a rubbly rock of this kind in the oolites, making by its decomposition a good corn land. For derivation &c. see Bristow's *Descriptive Catalogue of Rock Specimens* in Mus. Pract. Geol. [CORNSTONE.]

Brass (A.-Sax. *bras*). An alloy of copper and zinc. The proportions vary according to the required colour: four parts of copper and one of zinc form an excellent brass. It is usually made by heating copper plates in a mixture of native oxide of zinc, or calamine, and charcoal.

The terms *Brass* and *Coal Brasses* are also applied to the Iron Pyrites found associated with and in beds of coal. This brass is often of considerable value for making green vitriol or copperas, and is used for that purpose in Northumberland, Yorkshire, Lancashire, and Scotland. This is effected by exposing the pyrites to the action of the atmosphere in widespread heaps, by which means the sulphur, becoming converted into sulphuric acid, combines with the iron and forms sulphate of protoxide of iron, which is dissolved out and recrystallised. (Ure, *Dict. of Arts, Manufactures, and Mines*, i. 719, iii. 557.)

Brasses, Monumental. This name has been given to monumental slabs of brass, on which are carved effigies in outline. Of such memorials, the earliest on record is that of Simon de Beauchamp, who died at the beginning of the thirteenth century; but the earliest of the brasses which have been preserved to the present time is that of Sir John d'Abernon, who died in 1277 and was buried at Stoke d'Abernon in Surrey. The value of such monuments, as illustrating the costume, manners, and habits of our ancestors, can scarcely be overrated; but their number has unfortunately been greatly lessened by the wanton spoliation and destruction which took place at the Reformation and still more during the civil war of Charles I. and the Commonwealth. (*Manual of Monumental Brasses*, Oxford 1848. See also the works of Waller, Boutell, and Haines on the same subject.) The use of such memorials is again coming into fashion; but the habit of using fancy dresses for the effigies of persons deceased cannot be too strongly blamed. In Westminster Abbey is a monumental brass, on which Sir Thomas Wilson, the deliverer of La Valette in 1815, is represented with his wife in a costume belonging to the age of the Plantagenets. Memorials which would otherwise be most valuable, are thus rendered not only worthless but deceptive. (*Edinburgh Review*, July 1863, p. 73.)

Brassage. A sum formerly levied to defray the expense of coinage, and taken out of the

BRASSART

intrinsic value of the coin. The term is supposed to be derived from *brachiorum labor*.

Brassart. In Plate Armour, the piece which protected the upper arm, between the shoulder-piece and the elbow.

Brassica (Celt. *breic, cabbage*). One of the most extensively cultivated genera of the *Crucifera*, yielding as garden vegetables the Cabbage, Kale, Broccoli, Cauliflower and Turnip, with their varieties; and as farm crops, the Turnip, the Swedish Turnip and the Rape. The Mustards are sometimes associated with *Brassica*, sometimes separated under the name of *Sinapis*.

Brassicaceae (*Brassica*, one of the genera). One of the names given to the natural order *Crucifera*.

Brattice. In Mining Engineering, the great general shaft is divided, by a partition of iron plate and other fit material called a brattice, into two chambers, which serve as up-cast and down-cast shaft for the ventilation. Mining engineers also use the term to express the separation of the currents, which takes place occasionally on the sides of a shaft, which are then said to constitute a *natural brattice*, or one independent of any artificial ventilation.

Braunite. A native sesquioxide of manganese, composed, when pure, of 69·68 per cent. of manganese and 30·32 oxygen. It occurs both crystalline and amorphous, of a dark brownish-black colour, with a submetallic lustre. It is distinguished from other ores of manganese by its greater hardness.

Braxy. A disease in sheep, caused apparently by constipation. It is very prevalent in the Highlands of Scotland.

Brayera (named after Dr. Brayer, who observed its medicinal properties). A genus of *Rosaceae* found in Abyssinia, where it has long been in use as an efficacious vermifuge. *B. anthelmintica*, the only species, is a tree with pinnated leaves, and dioecious flowers. The female flowers want both stamens and petals.

Brasil Nut. A South American fruit, commonly sold in the markets of London; it is the seed of a large fruit-tree, called *Bertholletia excelsa*.

Brasil Wood. A wood imported from South America and the West Indies, where it is produced by certain species of *Casalpinia*, especially *C. echinata* and *C. brasiliensis*—large trees with pinnated leaves, showy yellow flowers, and long richly coloured stamens. It is used for the preparation of a red dye, but the consumption of it in this country is inconsiderable.

Brasing. The act of joining together two pieces of metal by means of brass solder melted between them. The best description of solder is made of 9 parts of brass to 1 of tin; hard solder is made of 2 parts of common brass, $\frac{1}{2}$ of a part of zinc, and $\frac{1}{4}$ of a part of tin. The solder for the precious metals is made of 66 parts of silver to 33 parts of common brass.

Breach. In Fortification, a gap or opening made in any part of the walls of the besieged place by the cannon or mines of the besiegers.

BREAD

Bread (A.-Sax.; Ger. *brod*). This important article of food is made of the flour of different grains; but it is only those which contain gluten that admit of conversion into a light or porous and spongy bread, of which *wheaten bread* furnishes the best example. When flour is made into a *dough* by the addition of a little water, rolled out into thin cakes, and more or less baked, it forms *biscuit*. For the formation of *bread*, a certain degree of fermentation, not unlike vinous fermentation, is requisite, care being taken to avoid acetous fermentation, which renders the bread sour and disagreeable. If dough be left to itself in a moderately warm place (between 80° and 120°), fermentation comes on. When this is rapid, it is *acetous*; so that to effect that kind of fermentation requisite for the production of the best bread, a *ferment* is added, which is either *leaven* (dough already in a fermenting state) or *yeast* (the matter which collects in beer in the act of fermentation). Of these ferments, *leaven* is slow and uncertain; *yeast* is more effective; and when clean and good, it rapidly induces *panary fermentation*; but it is often bitter, and sometimes has a disagreeable smell and taste.

All, then, that is essential to make a loaf of bread, is dough to which a certain quantity of yeast has been added. This mixture is put into any convenient mould, or form, or shaped into a mass; and after having been kept for a short time in rather a warm place, so that fermentation may have begun, it is subjected to the process of baking in a proper oven. Carbonic acid is generated; and the viscosity or texture of the dough preventing the immediate escape of that gas, the whole mass is puffed up by it, and a light porous bread is the result. Along with the carbonic acid traces of alcohol are produced, but so insignificant as not to be worth notice; hence the attempts to collect it upon a large scale have entirely failed in an economical point of view. Other flour besides that of wheat will under similar circumstances undergo panary fermentation; but the result is a heavy, unpalatable, and often indigestible bread; so that the addition of a certain quantity of wheat flour is almost always made. It is the *gluten* in wheat which thus peculiarly fits it for the manufacture of bread, chiefly in consequence of the tough and elastic viscosity which it confers upon the dough.

It is well known that *home-made bread* and *baker's bread* are two very different things. The former is usually sweeter, lighter, and more retentive of moisture: the latter, if eaten soon after it has cooled, is pleasant and spongy; but if kept for more than two or three days, it becomes harsh and unpalatable. The cause of this difference may perhaps be obvious from the following details of the operations of the wholesale baker.

In making his dough he takes the water, or part of it, which he intends to use, and having slightly warmed it, dissolves in it a certain portion of salt; then he adds the yeast, and then a certain quantity of flour. This mixture is set

BREAD

aside in a warm place, where it soon begins to ferment. This process is called *setting the sponge*; and according to the relation which the water in it bears to the whole quantity to be used in the dough, it is called whole, half, or quarter sponge. The evolution of carbonic acid causes the sponge to heave and swell; and when the surface bursts it subsides, and then swells again and so on; but the baker is careful to use it before this fermentation has communicated sourness to the mass. He then adds to the sponge the remaining quantity of flour, water, and salt which may be required to form dough of proper quality and consistence, and incorporates the whole by long and laborious kneadings till the entire mass acquires uniformity, and is so tough and elastic as to bear the pressure of the hand without adhering to it. It is then left for a few hours, during which fermentation goes on; and the inflated mass is again kneaded, so as to break down any lumps or portions which had accidentally escaped diffusion in the first operation, and to confer perfect uniformity on the whole. The dough is then weighed out into loaves, which are shaped, and put aside in a warm place for an hour or two, during which they swell up to about double their original size; they are then put into the oven and baked; during which operation they again enlarge considerably in bulk, in consequence of the dilatation of the previously generated carbonic acid pent up in the dough: for, as soon as the mass is exposed to the heat of the oven, the fermentation is ended.

If we compare the baked loaf with the flour of which it is composed, we shall find that panary fermentation has produced a considerable change in the latter. The gluten and the starch, which (exclusive of a little sugar) were the principal components of the flour, have mutually acted upon and partially altered each other; the toughness and viscosity of the gluten is gone, and the starch no longer forms a gelatinous mixture with hot water; a little sugar is generally formed, as well as alcohol; but the principal cause of the change in the characters of the flour is the evolution of carbon and of oxygen in the form of carbonic acid, the production of which is independent of the presence of external oxygen (or of air). Small quantities of alum are generally used by the London bakers with the view of whitening the bread; for it may be observed, that whatever may be the quality of the flour which is used, home-made bread is of a comparatively dingy hue. According to Mr. Accum (*On the Adulteration of Food*), the requisite quantity of alum for this purpose depends upon the quality of the flour. The mealman, he says, makes different sorts of flour from the same kind of grain. The best flour is chiefly used for biscuits and pastry, and the inferior kinds for bread. In London several kinds of wheaten flour are brought into the market; they are called fine flour, seconds, middlings, coarse middlings, and twenty-penny. Beans and peas are also, according to the same authority, fre-

quently ground up with London flour. The smallest quantity of alum used is from three to four ounces to the sack of flour of 240 pounds. Much has been said as to the deleterious effects of the alum in London bread, in producing dyspepsia and constipation; but the quantity used is too small to justify such statements.

Another article occasionally employed in bread-making is carbonate of ammonia. As it is dissipated by the heat of the oven, none remains in the baked loaf. It renders the bread light, and perhaps neutralises any acid that may have been formed (exclusive of carbonic acid); but it is not much employed. To some kinds of biscuits it gives a peculiar shortness. The French and Belgian bakers have been accused of using sulphate of copper for improving the colour and quality of bread; this, if employed in infinitesimal quantities only, is a really dangerous addition. According to Mr. E. Davy, bread, especially bread made of indifferent flour, is materially improved by the addition of a little carbonate of magnesia, in the proportion of twenty to thirty grains to the pound of flour; it requires to be very intimately mixed with the dough. The most nefarious adulteration of bread consists, perhaps, in the addition of certain insipid and colourless earthy substances; such as pipe-clay, porcelain-clay, and plaster of Paris. These, however, are rarely resorted to; though in one instance the writer of this article had occasion to examine some *biscuits*, which were adulterated with gypsum to the amount of 10 per cent.

The manufacture of bread as carried on in this country is generally a dirty and disgusting process; it is usually conducted in cellars, infested with beetles, and the kneading of the dough is performed with the naked arms or feet of the operators. It has lately been proposed to supersede these processes by the use of machinery, and a company has been established for effecting this desirable change.

Unfermented Bread.—Instead of deriving the carbonic acid (which gives lightness and porosity to the bread) from fermentation, it has been proposed to substitute less indirect processes for its introduction into the dough. Thus, instead of adding salt to the mixture of flour and water, hydrochloric acid and carbonate of soda, in such exact proportions as to form common salt (chloride of sodium), have been used; in this case the evolved carbonic acid is received into the dough, causing it to rise to the same extent as by fermentation, and good and palatable bread may be thus made; but it is very difficult to obtain it free from small doughy lumps, and the commercial hydrochloric acid often contains traces of arsenic.

Aërated Bread.—Under this name loaves are made by Dr. Dauglish's patent, in which an aqueous solution of carbonic acid prepared under great pressure is mixed with the flour in a proper apparatus, so as to produce a vesicular dough when the pressure is removed. The

BREAK

process is rapid, and prevents such deteriorations of the flour as are said to be attendant on fermentation in the usual way. (See, in reference to the manufacture and composition of bread, *Ure's Dictionary*; *Watts' Dictionary*; *Muspratt's Chemistry*.)

New and Stale Bread.—It has generally been assumed that the difference between newly baked bread and that which has been kept for a few days depends merely upon relative dryness, or upon the loss of water by the latter. But it has been shown by Boussingault (*Ann. Chim. et Phys.* xxxvi. 492) that a stale loaf which had been kept for six days had only lost about 1 per cent. of water, and that all the qualities of new bread were restored by placing it for an hour in the oven. So also, when a thick slice of stale bread is toasted, the crumbly interior loses its harshness, and acquires the taste and texture of newly baked. The difference, therefore, between new and stale bread is supposed to depend upon difference in molecular arrangement.

Break. In Architecture, the projection from the face of a building is called a break, whether it arise in plan or in elevation. It is one of the most legitimate ways of securing variety of line; but the exaggerated effects of the break introduced in the cinquecento and the Louis XIV. styles of architecture prove that considerable discretion must be exercised in their use. They should be caused by some necessity of the plan, or of the disposition of the structure: a break, introduced merely as a break, is a decided mistake in a composition.

Breakers. Waves that break, or fall over, from the shallowness of the water. In a gale, the tops of the seas generally break in this way, more or less, from the progressive motion of the water at the surface before the wind, which is exceedingly dangerous for open boats. This is never confounded with the falling over of the whole wave, as the surf falls over on the beach.

Breaking Joint. In Architecture, that disposition of stones and bricks in their courses by which vertical joints are not allowed to fall over each other. (See diagrams to BOND, ENGLISH and FLEMISH.)

Breakwater. An artificial bank of stones, or a timber structure, sunk to break the violence of the sea before its entrance into a roadstead or harbour. The Roman emperors erected many structures of this description, which survive to the present day to show the mode of construction adopted, such as the breakwater of the harbour of Civita Vecchia, still in good repair, and many of the ports of Italy. More recently the system of thus forming an artificial barrier to the sea has been adopted at Cherbourg and Cette in France; at Plymouth and Portland in England; at Buffalo and at the mouth of the Delaware in the United States, in all of which positions breakwaters are formed of immense magnitude. The mode of construction adopted in all such cases is to cast down large stones, from either ships or railway waggons,

BREASTPLATE

whenever it is possible to connect the works with the mainland; and to allow them to assume their angle of repose under the action of the tides and currents. The top of the masonry structure is then covered with large blocks of artificial stone as at Cherbourg, or with paving laid with a regular slope as at Plymouth; and a wall is erected upon the top of the sea slope, after the work has attained its stability under the action of the sea. Cherbourg breakwater is the most gigantic work of the kind executed in ancient or modern times, and it is a noble monument of the skill and perseverance of the French engineers; Plymouth breakwater is much smaller, but it was completed within a much shorter period than its French rival; we have still to learn whether Portland breakwater is sufficiently settled to resist the effects of the sea; for at Cherbourg a storm occurred in 1808 which swept away all the upper structure, and 400 men of the garrison stationed on it, after it had supported the attack of several winters. The Buffalo breakwater is erected to protect the harbour against the storms of Lake Erie, which are often very serious.

Bream (Fr. brame). The name of a soft-finned fish, common in many of the lakes and rivers of England, and one that breeds freely and thrives in ponds if there be sufficient depth of water. It is the type of a particular subgenus of the Carp family (*Cyprinidae*), which Cuvier has characterised under the name of *Abramis*. [LARRUS.]

Breaming. In Nautical language, signifies cleaning the bottom of a vessel by fire. When the vessel is aground, fire being applied to the bottom loosens the pitch, or composition of sulphur and tallow, with which the bottom is sometimes covered to defend it from the worms, and which is then scraped off, together with the barnacles, grass, weeds, &c., that adhere to it.

Breast Plough. A kind of spade or shovel, with a cross piece at the extremity of the handle, which is applied to the breast, and by which the operator skims off a thin slice of turf from a grassy surface, as if he were ploughing.

Breast Wheel. In Hydraulics, the name given to a water-wheel so placed as to be struck by the stream of water nearly on a level with the axle, the lower quadrant of the circumference on the side opposed to the stream being placed in a *race* or channel concentric with the wheel, through which the water is conducted in its descent from the higher to the lower level, and in falling on the float boards within the channel acts both by its momentum and weight.

Breast-hooks. In Shipbuilding, are strong curved timbers placed parallel to the surface of the water within the bows, for the purpose of strengthening and consolidating the upright timbers.

Breasting. Breasting up a hedge is cutting the face of it on one side, so as to lay bare the principal upright stems of the plants.

Breastplate. [CURRASS.]

BREASTSUMMER

Breastsummer. [BEAM, in Architecture.]

Breastwork. In Fortification, a hastily constructed parapet, generally without a banquette.

Breathing. [RESPIRATION.]

Breccia (Ital.). A collection of angular fragments of any hard rock cemented into a compact mass, either by carbonate of lime or other cementing medium. Rounded fragments under similar circumstances make *conglomerate* or *puddingstone*. They have the distinctive quality of showing no trace of magnesia, but are capable of taking a fine polish.

Brecciated Agate. Is a variety of Agate composed of fragments of Jasper, Bloodstone, Carnelian, &c., cemented together by Chalcedony.

Breech of a Gun. The solid part behind the bore.

Breech Loader. A term applied to a cannon or smaller firearm which is loaded by the insertion of the charge at the breech instead of at the muzzle. The earliest cannon made in Europe were breech-loaders, having the charge inserted in iron cylinders, which were fixed in their place in the breech of the gun by a wedge. Specimens of these ancient breech-loaders may be seen in the Rotunda at Woolwich. Breech-loaders have now almost entirely superseded muzzle-loaders for sporting purposes; and a committee has just recommended that the whole British army shall be furnished with them. Their chief advantages are rapidity and safety in loading, and facility in examining and cleaning.

All the rifled cannon of less than 6·3 inches calibre in our service are breech-loaders; but no plan of breech-loading as yet tried has been found sufficiently safe for heavy guns fired with large charges. The navy especially object to this system for large guns, alleging that the men are afraid of it, and that it causes too much smoke between decks.

In the Armstrong rifled gun for land service, the breech is closed by a vent-piece or block of iron or steel, which is dropped into a slot behind the charge, and is then screwed tightly up into its proper place.

Breeching or Breech Band. Part of the harness of a carriage horse, by means of which he is enabled to push the carriage to which he is attached backwards, or to support its pressure in going down a hill.

Breeching Loop. A loop of metal at the breech end of naval guns, through which a rope called the *breeching* is passed and secured to the sides of the vessel, to prevent the guns recoiling too far, or rolling across the ship in a seaway.

Breeding in and in. The system of close-breeding, which has been applied with much success in the rearing of cattle and race-horses, is sometimes thus designated. (See Nicholas Hanky Smith, *Observations on Breeding for the Turf*, and *Westminster Review* for July 1863, p. 98 &c.)

BRETWALDA

Breeze (Fr. *bris*, *débris*: Wedgwood). The larger refuse arising from passing cinders through a sieve; they are much employed by brickmakers for the purpose of calcining their bricks, and for mixture with the clay when it is too fat for ordinary purposes.

Breeze-ries. [ESTRAÏNÆ.]

Brehon Laws. The ancient laws of the Irish are so termed, from an Irish word signifying *judges*. It is supposed that some of the written collections of these laws which still exist are of great antiquity; as old, perhaps, as the earlier ages of the Christian era. Prior to the Anglo-Norman invasion, Ireland was governed by these laws. (Lord Lyttelton's *Henry II.* vol. v. p. 28, and the authorities there referred to; Goldwin Smith, *Irish History and Character*.)

Breislakite. A variety of Augite occurring, in wool-like flexible fibres, of a chestnut-brown colour, at Capo di Bove, in cavities of the older lavas of Vesuvius. It was named after the Italian geologist Breislak.

Breithauptite or Antimonial Nickel. This mineral, a native antimonide of nickel, was formerly found in the Andreasberg mountains, and is now met with in the Pyrenees, especially in the neighbourhood of the Pic du Midi d'Ossola. It occurs in thin hexagonal plates, of a light copper-red colour inclining to violet when newly fractured; also arborescent and disseminated: and it has been observed in a crystallised form among the products of blast-furnaces. Named after Professor Breithaupt, of Freiberg.

Bremer Green. A pigment composed of carbonate of copper, carbonate of lime, and alumina.

Brentus. A Fabrician genus of Coleopterous insects, belonging to the Weevil tribe, or *Curculionidæ*; now the type of a family, called *Brentidæ*, including about eight genera and seventy species. These insects are peculiar to hot climates: only one species, the *Brentus italicus*, is found in Europe, and this has been referred by Germar to a particular sub-genus, *Arrhenodus*, all the other species of which are natives of the New World.

Bressummer. [BEAM.]

Brettices or Brattices. In coal mines, wooden plankings to prevent the falling in of the strata.

Bretwalda. In English History, the title of an office which conferred a certain supremacy on one of the Anglo-Saxon princes. The need of a common chief over all the Germanic provinces of Britain arose from the great number of independent chieftains, which was only in course of time reduced within the compass of the 'Heptarchy.' The common warfare against the British tribes could scarcely be carried on without a dictator: and this office was naturally conferred on the most powerful chief, or on the prince whose land was most exposed to hostile inroads. The appointment was determined probably by the choice not only of the other kings, but of the

BREUNNERITE

collective nobility and ealdormen. According to Bede, the first chieftain who held this office after Ælle was Ceawlin, the grandson of Cerdic (Lapenberg, *History of England under the Anglo-Saxon Kings*.) [HEPTARCHY.]

Breunnerite. A natural carbonate of magnesia and iron. It generally occurs crystallised in detached, embedded rhombohedrons in chlorite-slate and Serpentine; sometimes, though rarely, in Gypsum. The only British locality where it has been met with is Unst, in Shetland; the principal foreign localities are St. Gothard, the Tyrol and Norway.

Named after Count Breunner.

Breve (Ital.). In Music, a note formed thus \square without a tail, and equivalent to two semibreves or four minims. Music marked with the words *Alla Breve*, or with the prefix $\frac{1}{2}$, has, properly, one breve in each bar, although the bars may be cut in two for facility of reading.

Brevet. In the French, this term signifies a royal act in writing, conferring some privilege or distinction, as brevet d'invention, &c. patent. It is applied in England to a commission giving army rank, as distinct from regimental rank. Brevet rank is attained either by distinguished service or by seniority in the army.

Breviary (Lat. *breviarium*). A book containing the offices of daily prayer according to the usage of the Roman Catholic church. The offices are seven; viz. matins, lauds, prime, tierce, none, vespers, and compline. Anciently all Catholics were required to recite the breviary daily. The injunction is now confined to the clergy; of whom it is still strictly exacted.

Brevicite. The name given to the better crystallised variety of Bergmannite which occurs in transparent colourless prisms, and in white radiated masses, at Brevig in Norway.

Brevier. In Printing, the name of a kind of small type, the size of that used in this work. [TYPE.]

Brevipennates, Brevipennes (Lat. *brevia, short; penna, quill; short-quilled*). An epithet applied by Cuvier to distinguish the first family of his order *Grallæ* (Echassiers); the ostrich is the type of this family. [CURSORES.]

Brewing. [FERMENTATION.]

Brewsterite. A hydrated silicate of alumina, strontia, baryta, and lime, named after Sir David Brewster. It occurs in small grey or yellow transparent crystals, at Strontian in Argyleshire; at the Giant's Causeway, lining cavities in amygdaloidal rocks; also in France, and in the Pyrenees.

Brewstoline. A transparent colourless fluid detected in Siberian Amethyst by Sir David Brewster, after whom it was named. It also occurs in minute cavities in crystals of Topaz, Chrysoberyl, Quartz from Quebec, and in the blue Topaz of Aberdeenshire.

Brexia (Brexia, one of the genera). A small group of perigenous Exogens sometimes erected into a natural order of the Saxifragal

BRICK

alliance. They are not, however, very closely connected by any well-marked character.

Briançon's Theorem. In Conic Sections, is the reciprocal of *Pascal's theorem*, and was first given by its discoverer, Briançon, in the *Journal de l'École Polytechnique*, cah. 13. It is thus enunciated: 'The three diagonals of every hexagon circumscribed to a conic meet in a point,' and may be easily deduced from the anharmonic properties of conics. By allowing two or more sides to coincide, numerous useful corollaries may be deduced.

Bribery (Nor. Fr. *bribe* [de pain], a *piece of bread*, hence a sop to stop the mouth: Wedgwood). In English Law, is a term comprehending the offences of judges, ministerial officers, &c., receiving rewards or considerations to act contrary to their respective duties, which are severally misdemeanours at common law, and also punishable under several statutes. But in its most ordinary signification, it is the giving or receiving money to procure votes at parliamentary elections, or elections to public offices of trust. The statute which at present chiefly regulates the offence of bribery at parliamentary elections is 17 & 18 Vict. c. 102, which repealed all the previous Acts on the subject, and has been continued and amended by subsequent statutes. Bribery is now a misdemeanour, punishable in the case of the person bribing with a fine of 100*l.*, and in the case of the person bribed with a fine of 10*l.* These pecuniary penalties are in addition to the ordinary punishment by fine and imprisonment consequent on misdemeanours. The offence of bribery is now extended so as to include every variety of corrupt inducement, direct or indirect, to vote or refrain from voting at a parliamentary election, or to procure or endeavour to procure the return of any person to serve in parliament, or the vote of any voter at any election. And any candidate at an election for any county, city, or borough, declared by an election committee guilty, by himself or his agents, of bribery, is incapable of being elected or sitting in parliament for such county, city, or borough, during that parliament.

Brick (A.-Sax. *brice*, a *fragment*: Wedgwood). A piece of clay earth, sometimes mixed with coal ashes, chalk, and other substances, formed into a mould, and burnt in a kiln, or clamp, is called in Architecture a brick. The earth used for this purpose is of two sorts; the one a stiff clay, with little or no extraneous matter, which produces a hard red brick; the other a yellowish clay which is very fat, and is called loam, and which requires to be tempered with sand, or breeze (a light kind of ash), to produce a grey-coloured brick. The earth is usually dug some time, and exposed to the action of the atmosphere, and it is mixed with the sand, or breeze, in a pugmill, care being taken to introduce as little water as possible. In moulding the bricks, which is usually done by hand (though of late machinery has been applied to this purpose), it is calculated that

BRICK

a good workman will turn out as many as 5,000 bricks in a day of fifteen hours; the bricks are then allowed to dry by being exposed on the backs, and from them they are carried to the kiln, or the clamp. Kiln-burnt bricks are usually more regular in their shape than clamp-burnt ones, and they are produced with a considerable economy in the fuel; but they require more space and more time than the clamp-burnt bricks, and therefore in London and in places where time is an important element of the process of manufacture, the kiln-burnt bricks are but seldom used. When, however, they are resorted to, the kilns are usually made about 13 ft. long, by 10 ft. 6 in. wide, and 12 feet high, and are provided with a regular furnace; when clamp-burnt bricks are used, the *clamp* is formed of the unburnt bricks themselves, generally oblong in plan, and the foundations are laid in *places* (or in previously made underburnt bricks). Each course of bricks is laid on a layer of breeze, or cinders; and flues are formed through the mass of the bricks which are filled with firewood, clay, or breeze; the outer wall of the structure is cased with place bricks, and the draught is regulated by closing the apertures with hurdles covered with clay; the burning may continue from twenty to thirty days. Until within a few years the whole of the produce of the brick yard was subject to an excise, and the dimensions of the bricks were made $8\frac{1}{2}$ inches long, $4\frac{1}{2}$ in width, and $2\frac{1}{2}$ in thickness; but at the present day there is no limitation to their dimensions.

The different varieties of bricks known in trade are the *malms*, or *facing bricks*, which are of a yellowish uniform colour and texture (the white, or the *Suffolk bricks*, are a variety of these); the *seconds*, not quite so uniform in colour and texture as malms; *red and grey stocks*, the former being burnt in kilns, the latter in clamps, both of them inferior to the quality of malms; *place bricks*, sometimes called *sandell* or *samel* bricks, which were those furthest from the fire in the kiln, and therefore the least burnt—these should never be used in a building where durability is an object of importance; *hurrs* or *clinkers*, which are masses of several bricks run together in the clamp, or kiln, from the violent action of the fire; *shuffs*, or the broken unburnt particles of the bricks. They make at present a kind of fire-brick $8\frac{1}{2}$ in. \times $2\frac{1}{2}$ in. \times $4\frac{1}{2}$ in. of the blue Staffordshire clay; and some very beautiful goods are manufactured from the clays of the blue lias formation at Rugby, Ardsey, and at various other places. *Paving bricks* are made for the purpose for which they are named; *compass bricks* are circular on plan, used chiefly in walling or *steining* wells, or such works; moulded bricks are made to any shape which may be required; *Willoughby's clinkers* and *Dutch or Flemish clinkers* are chiefly used in stables, the Dutch clinker being 6 in. \times 3 in. \times 1 in. *Fire bricks, tiles, and retorts* are made of every size and of every form to resist the action of the intense heat of the furnace; they are made of a kind of clay that contains more silica

BRIDGE

in combination with the alumina than is the case with ordinary bricks.

Brick Clay. A common variety of clay adapted to the making of bricks. Many mixtures and combinations of silicates of alumina with silica, iron, and alkaline earths are available; but the best kinds contain little of the latter materials, as they are apt to cause the bricks to melt and run together into a kind of glass in the kiln. There is no special geological age for brick clays, as they belong indifferently to the oldest and newest formations. The red colour of bricks is derived from the oxide of iron that most clays contain.

Brick Wogging. In Architecture, the brickwork carried up and filled in between timber framing.

Brick Trimmer. A brick arch abutting against the wooden trimmer in front of a fireplace, to guard against fire.

Bricklaying. The art of building in bricks, which is of the remotest antiquity; Pausanias mentions many buildings in Greece thus constructed, and in Rome such buildings were very common. The walls of Babylon, Nineveh and Persepolis, and some of the pyramids of Egypt, were also of brick.

Bricole. [BILLIARDS.]

Bridewell. A house of correction for offenders is commonly so called in England. The name is derived from the ancient London house of correction, originally a hospital founded by Edward VI. on the site of St. Bride's well, in Black Friars, a well-known object of pilgrimage in Roman Catholic times. The original Bridewell is under the control of the Lord Mayor, and used as a receptacle for vagrants, &c., within the jurisdiction of the City.

Bridge (A.-Sax. *brycg*). In Architecture, the expression is used to designate the structure for the purpose of connecting the opposite sides of a river, gorge, or valley, &c., by means of certain materials, forming a roadway from one side to the other, or occasionally carrying the waterway of a canal, in which case it would be specifically called *Aqueduct*. It may be of stone, brick, iron (cast or wrought), timber, or suspended from chains; or the roadway may be carried by means of boats, according to the wants and the resources of the position where the bridge is required.

In tracing the history of bridges amongst different nations, it is easy to discover that local causes had great influence on the style of construction adopted in them. A nation may have attained the highest point of art in its other buildings, and nevertheless may have left nothing worthy of our admiration in the nature of a bridge. In Egypt, for example, intersected as it is by a large and wide river subject to periodical inundations, the construction of bridges would have been as difficult as it would have been useless before the introduction of railroads. All the intercourse which commerce required was easily carried on by the assistance of boats; and as regards the passage of the canals with which the country abounded,

BRIDGE

their depth and breadth were so small as to require none but the most simple expedient for connecting their opposite banks, nor any which involved the employment of scientific construction. In Greece no vestige of a bridge occurs before its occupation by the Romans; but this, had the Greeks even been acquainted with the use of the arch, might be accounted for by reasons which were substantially the same as those which applied in Egypt. The country is, in fact, intersected by no river of magnitude, and even those which seem entitled to the name are rather mountain torrents, than those immense sheets of water, swelled in their course by innumerable streams, that are to be found in other countries. In this case, nothing more would be required than a single arch, whose abutments would be found in the solid rock which the streams separated.

But when we turn to Italy, we find a country watered by many and deep rivers, and intersected with deep ravines, where bridge architecture became a necessary study, not only for the accommodation of the inhabitants of the cities, but also for the frequent military expeditions of the people who succeeded in impressing their rule upon its provinces. Rome from its commencement must have put into requisition considerable skill in bridge-building across the Tiber, rapid and subject as it was to sudden floods. The earliest bridges here were of timber; such was that which joined the Janiculum to the Mons Aventinus, and was called the Pons Sublicius from the *sublicia* (stakes) of which it was formed. Without enumerating the bridges of Rome, some of which are still standing to attest the science of their architects, we must mention the Pons Narniensis on the Flaminian Way near Narni and about sixty miles from Rome. It was built by Augustus; and vestiges of it remain to the present day, one arch above 150 feet span and 100 feet high being still entire. But of the works of art of this description, the most wonderful ever executed in the Roman times was the bridge built by Trajan over the Danube. It consisted of twenty piers, 150 feet in height from their foundation, and 170 feet apart; its breadth was sixty feet. This stupendous work was destroyed by Hadrian, the successor of Trajan, under the pretence that it might serve as a passage for the barbarians if they became masters of it; but some writers have said that it was through envy of the fame that attached to its founder. Over the Tagus, in Spain, an ancient Roman bridge is still standing at Alcantara. It consists of 6 arches, the two centre arches being of 100 feet span, and 150 feet above the ordinary water-line; the whole length of the bridge is about 612 feet. Of the temporary bridges of the Romans, the most celebrated was Cæsar's bridge thrown over the Rhine; it had the advantage of fenders on the upper side of the stream, and stood remarkably well.

From the fall of the Roman Empire to the revival of the arts, the history of bridge archi-

ture is rather a blank, with the exception of some mediæval structures and the Moorish works of Spain. It appears from Gauthier, who uses the authority of Agricola of Aix, that when the arts began to revive in Europe an order was founded, under the name of the Frères Pontiers, and that under them was begun in 1176 the bridge at Arignon, of 18 arches and about 3,000 feet in length; this bridge has since been destroyed. In Spain the bridge of Orense, and of Martorel, may be referred to as specimens of the style of bridge-building then adopted; and the old London and the Dresden bridges are also good samples of mediæval bridges. In 1364 a bridge of 3 arches was constructed at Verona, the roadway sloping from the city; the largest of its arches is 159 feet 9 inches span; but a much larger arch was built at Vieille Brioude, in France, over the Allier, in the year 1454, of nearly 184 feet span, almost the greatest span of any stone bridge in existence. Amongst the most celebrated bridges of Italy is that of the Rialto, at Venice, whose span is 98½ feet. It was begun in 1588, and finished in 1591, from the designs of Antonio del Ponte (Sansovino's *Venice*), though by most authors absurdly attributed to M. A. Buonarroti. In this city alone there are no less than 339 bridges; but they are mostly of small span. We must not omit to notice in this place the bridge della Santissima Trinità at Florence, by Amminati, which, as Milizia has truly observed, has not been surpassed since the revival of architecture. It is of 3 arches, the middle one of 96 and the two side ones of 86 feet span, the width of the piers being 26 feet 9 inches; the breadth of the carriage and the foot ways between the parapets is 33 feet. The arches are portions of a very flat ellipsis; the springing is in a line with the pier and the rise in the centre not much more than ¼ of the chord; the arches, in fact, are after the fashion of the Tudor arches in this country, the point at the summit, which is extremely obtuse, being hidden by the rams' heads sculptured upon the key-stones. During the last two centuries the French have advanced their bridge architecture to a great degree of excellence, but more particularly so in the latter end of the last century, in which appeared Perronet, the father of the modern system of the art, whose elegant designs have not since been improved upon either in France or in any other country. The beautiful bridge over the Seine at Neuilly is by him; it consists of five arches, each of 128 feet span and 14½ feet rise; it was finished in 1774, and remains a splendid monument of the powers of its designer. Some of the more modern specimens of their bridges do great honour to the French school, for their union of beauty of form with sound engineering.

In England the progress of bridge-building is kept pace with that of the Continent, although latterly the engineers appear to have been driven in the race for ugliness. Our bridges cannot boast the elegance of design of

BRIDGE

the French or the Germans, they can at any rate lay claim to great merit of boldness in conception and execution. The most celebrated work of the beginning of the last century is the bridge over the river Taffe, near Llantrissant, in Glamorganshire, the work of a country mason, William Edwards; it is 140 feet span with a versed sine of 35 feet, and was erected in 1755. Subsequently Smcaton, Brindley, Jessop, Mylne, Rennie, and Telford executed the bridges connected with their names, and these were followed by the Stephenson, Brunels, Locke, Bidder, Hawkshaw, Tierney Clarke, Fowler and others. We may mention as the productions of the earlier school, the bridges of Hexham, Dumballock, Dunkeld, Stoneleigh, Kelso, Earn, Waterloo, London, Southwark, Limerick, Chester, Carlisle, &c.; and, of the later, we may refer to the High Level and the Menai and Conway plate bridges, the Saltash, the Stockport, Malaunay, and Barentin viaducts, Trent, Victoria, and other bridges; all of which display a profound acquaintance with the laws of bridge-building. The dimensions of the Menai Bridge, of the Chester and Holyhead Railway, and of the Saltash Bridge, in fact, surpass any of those yet attempted; they are, for the first, 459 feet span in the two central openings and 230 feet at the sides; for the second, 433 feet 8 inches in the arches over the navigable part of the river. Evidently some new principles of construction had to be introduced before such gigantic operations were undertaken, and therefore it is that wrought iron was employed. Some idea may be formed of the care and pains taken by Mr. Stephenson in working out the problem of this application of a new material, from a perusal of Mr. Clark's book on the Britannia and Conway Tubular Bridges.

Of timber bridges, the boldest and most ingeniously constructed in Europe was that at Schaffhausen, in Switzerland, destroyed by the French in 1799. It was designed and executed by Ulric Grubenman, a village carpenter of Teuffen, in 1758. The total length of the bridge was 364 feet; but it was relieved by a pier in the middle of the river. In America there are some extraordinary specimens of timber-bridge building. Such is the Trenton bridge over the Delaware, built in 1804 by Burr: its chord line is 200 feet and its versed sine 32 feet, the height or thickness of the timber framing at the crown being only 32 inches. The bridge called Colossus, over the Skuykill, is 340 feet span, with a versed sine or rise of only 20 feet, and the thickness of the timber at the vertex is only 7 feet; it was the work of a person named Wernwag. Besides these two, there are numerous other timber bridges in America worthy the notice of the reader, such as the bridges built upon the systems of Fowey, Howe, Brown, McCallum, &c.

We shall close this portion of our subject by a reference to the suspension bridges which were so much the fashion some years ago, though at the present day there is rather a prejudice against them owing to the failure of

many such structures. Still, the successful resistance of the Menai, the Hammersmith, the Kiel, and the Pesth bridges proves that when properly designed this style of bridge is admirably adapted to a country which is not able to embark large capitals in executing such works; and they also induce us to believe that the cause of the failures is to be sought in the mode of employing the chains, especially when the iron wire has been substituted for them. In suspension bridges the most trying circumstance under which they can be placed is when a long file of infantry is passing over them in military time; the effect of the heavy regular tread of the soldiers is to produce the same result which isochronous impulses recurring constantly upon a pendulum would do. Suspension bridges have been raised by semi-barbarous nations; Mungo Park found a rude adaptation of them in the heart of Africa; and Don Antonio da Ulloa found them applied in the Cordilleras for the communications between the interior and the coast.

In the building of bridges, where piers are required in the midst of the stream for the support of the arches, it is important to place them as nearly as possible at right angles to the stream or current, and the piers should present to the latter the form of an equimarginal spherical triangle (of about 60 degrees) in order the better to resist its force. The position of a bridge should not, moreover, be in a narrow part, nor one liable to swell with tides, or floods, inasmuch as the contraction of the waterway increases the depth and the velocity of the current, and may thus endanger the safety of the navigation, as well as that of the bridge itself. It is usual to construct bridges with an uneven number of arches; and this for several reasons, amongst which are the following: that the stream being usually most powerful in the middle, an egress through that part is better provided by having a central opening; and again, if the bridge be not perfectly horizontal, symmetry is gained by rising from the sides to the centre, and the whole roadway may be made of one continuous curve. When a bridge is horizontal throughout its length, much saving will take place in the centring, because two sets will suffice; if, however, the bridge be higher at the extremities than in the middle, the arches on each side of the middle one must decrease in dimension regularly, so as to be as nearly symmetrical as possible, and by this arrangement beauty is gained and the expense of centring is diminished, as the centres of one side will serve for the other. It is, however, to be observed in this matter, that the effect of a long row of flat elliptical arches, such as are now used in bridge-building, is to cause the horizontal line of the road to appear to defect; and as an æsthetical principle it may be affirmed that all bridges gain by being made to rise in the middle.

It is desirable to construct a bridge with as few arches as circumstances will admit of, as well for the passage of the water in a river, as

BRIDGE

for the passage of the boats that may pass up and down, not to mention the economy of labour in the fewer piers resulting from the small number of supports. When the river can be spanned by a single arch, no more should be allowed. The piers should be of sufficient solidity to resist the thrust, or push, of one arch independent of the other arches, so that the centring may be struck without danger of overturning the pier left unprotected (this principle has, however, been neglected in some recent examples, and the Pont St. Maxence by Perronet, and the Barentin Viaduct by Mr. Locke, may be cited as illustrations); and the piers should also be spread as much as possible on their base, and diminish gradually upwards. The method of laying the foundations in a river is usually by means of a cofferdam, which is a large enclosure, made by piling, round the space to be occupied by the pier, so as to render it water-tight, and then by pumping out the water, and keeping the space dry till the pier is built up to the ordinary level of the water. But where the bed of the river is loose, or when the expense of foundations is an object, the present style of executing them is by means of tubes which are brought over the spot they are intended to occupy, and the earth from the inside of them is removed by some of the processes

described in a pamphlet by Coulomb and by Mr. Hughes, who superintended the works at Rochester Bridge. When the pile tubes are thus driven to the depth required, they are filled with concrete up to the water's edge. Occasionally the method of founding by caissons may be resorted to; but it is now so well known to be attended with danger that it is rarely employed. In constructing the centres great care must be taken to make them incapable of bending, or swerving, while the arch is being turned, otherwise it will be crippled; and care must be taken that the centres should be so treated as to be easily removed on the completion.

We here subjoin a table of some of the most important bridges in Europe and America, chiefly in reference to their span and the height of their arches; the reader who may desire more information on the subject is referred to Gauthy's treatise *Sur la Construction des Ponts*; Reibel's edition of Sganzin's *Cours de Construction*; Michel Chevalier's work *Sur les Travaux Publics de l'Amérique*; Weale's *Bridges*; Henz's *Das Eisenbahnwesen in Nord Amerika*; Fairbairn and Edwin Clark's works *On the Britannia and Conway Tubular Bridges*; Navier, *Sur les Ponts Suspendus*; &c. &c.

BRIDGES. In a steamship, is the platform raised above the deck for the purpose of connecting the paddleboxes. It forms a post of observation from which the captain has an excellent view of the vessel's course.

BRIDGES, MILITARY. Temporary bridges are usually made with piles, trestles, boats, pontoons, or casks.

Pile bridges are applicable for rapid, shallow, and muddy rivers, where boats cannot be used.

Trestle bridges are easily made, and answer the same purpose.

Boat bridges are made by mooring boats alongside each other across a river, and laying trestles across them.

Pontoon bridges are generally used, as an army can carry pontoons about; where, however, they are absent, casks may be used as substitutes.

Bridgewater Treatises. In Scientific History, a series of works published in accord-

ance with the will of the Rev. Francis Henry, earl of Bridgewater, who died in 1829. Eight thousand pounds were vested in trustees, and placed at the disposal of the President of the Royal Society, Davies Gilbert, who appointed eight gentlemen to write treatises on subjects illustrative of the 'power, wisdom, and goodness of God, as manifested in the Creation.' The works are: 1. By the Rev. T. Chalmers, D.D., *The Adaptation of External Nature to the Moral and Intellectual Constitution of Man*. 2. By John Kidd, M.D., *The Adaptation of External Nature to the Physical Condition of Man*. 3. By the Rev. W. Whewell, *Astronomy and General Physics, considered with Reference to Natural Theology*. 4. By Sir Charles Bell, *The Hand, its Mechanism and Vital Endowments, as evincing Design*. 5. By Peter Mark Roget, M.D., *Animal and Vegetable Physiology, considered with Reference to Natural Theology*. 6. By the Rev. Dr. Buckland, *On Geology and Mineralogy*. 7. By the Rev. W. Kirby, *On the*

BRIDGING JOIST

History, Habits, and Instincts of Animals.
8. By William Prout, M.D., *Chemistry, Meteorology, and the Function of Digestion, considered with Reference to Natural Theology.*

Bridging Joist. [Joist.]

Bridles. On Shipboard, are short ropes serving to connect various portions of the base of a sail with the bowline, which otherwise only draws upon the corner of the sail.

Brief (Lat. brevis, *short*; Nor. Fr. bref). A word applied originally to a small written signification.

1. In Ecclesiastical Law, letters addressed from the pope to temporal princes or communities on subjects of discipline or public affairs are termed Apostolical Briefs. The name appears to have arisen from the difference of size between this smaller kind of instrument and the ample bullæ (bulls) of the popes. Apostolical briefs are usually written upon paper, though sometimes parchment is used. They are sealed in red wax with the seal of the Fisherman (sub annulo Piscatoris), which represents St. Peter casting a net into the sea. (Ciampini, *Discretatio de Abbrev. Muncr.*, cap. iii.)

2. In Law, the term Brief is applied to an abridged narration of the facts of a case prepared for trial, with or without a reference to points of law involved in it, drawn up for the preliminary instruction of an advocate.

3. The term Brief is applied in England to king's letters, issued to the archbishops, bishops, clergy, magistrates, and parochial officers, to authorise collections of money at the doors of the several churches and chapels throughout the country, in individual cases wherein application has been made for such assistance towards the building or repair of a particular church. This custom is supposed to have commenced after the disuse of papal briefs consequent on the Reformation; but of late years it has been dropped.

Bris (perhaps an abbreviation of brigantine). The general term for a vessel having two masts, with a boom mainsail, being otherwise square-rigged; that is, having her sails brought to yards hung horizontally by the middle.

Brigade (Ital. brigata, *a company*). This term implies either the union of two or more regiments or battalions of infantry or cavalry, or both together, either with or without artillery, under one command. In the artillery batteries are combined into brigades, as companies of infantry are into battalions. In the expedition to the Crimea in 1855, each infantry brigade was formed of three battalions. The commander of a brigade is called a brigadier-general.

Brigandine. A kind of scale-armour, worn by the light troops called *Brigades*; a name used during the middle ages in the sense of skirmishers, from Low Latin *briga*, *stiff*. (Wedgwood, *Dictionary of English Etymology*.)

Brigantine (Span. bergantin). A name often applied to a small brig of a few hundred tons. The older English form is *brigantine*.

BROADCAST

Briggs' Logarithms. The common or vulgar system of logarithms constructed on the base 10 is sometimes called Briggs' system, after their constructor Henry Briggs, a contemporary of Lord Napier, who discovered logarithms in the early part of the seventeenth century. [LOGARITHMS.]

Bright (A.-Sax. beorht; briht). In Painting, shining with light; a term applied to a picture in which the lights preponderate over the shadows.

Brillante (Ital.). In Music, prefixed to a movement, denotes that it is to be played in a gay and lively, or brilliant, manner.

Brimstone (A.-Sax. bren, *to burn*). A commercial name for refined sulphur. [SULPHUR.]

Bringing-to. Is the act of stopping the course of a ship through the water, so that she becomes nearly stationary. This is effected by brailing up the sails, or by so setting them as to counteract each other. The operation of bringing-to in a strong wind can rarely be performed without passing over a considerable space.

Bristol Diamonds, Bristol Stones. Small and brilliant crystals of colourless Quartz found in the Mountain Limestone of the vicinity of Bristol. They are occasionally used, in a cut and polished state, for ornamental purposes.

Britannia Metal. An alloy of tin with a little copper and antimony.

British Gum. When starch is exposed to a temperature of about 600° it becomes of a brownish colour, and so far altered in its chemical characters as no longer to form a blue colour with iodine; it is also soluble in cold water. In this state it is used, under the above name, by calico printers.

Broaching-to. In Sailing, is to allow the ship's head to incline rapidly to windward of her proper course. This is occasioned by negligence, and may result in the sails being taken aback and the masting of the vessel.

Broad Arrow. A cuneiform mark, placed on all stores and material belonging to the British Admiralty. It is unknown when this mark originated; but a penalty was affixed in 1698 to the use of it by any private person under the Act 9 and 10 Wm. III. cap. 41.

Broadcast. In Horticulture and Agriculture, is a method of sowing seeds by casting them or scattering them abroad, so as to distribute them evenly over the entire surface of the soil, in opposition to sowing in drills or rows. The operation of sowing broadcast is generally performed by the hand, the operator carrying the seeds in a bag or sowing sheet, or in a basket. There are also machines for sowing broadcast, but they are not much in use. In general, grasses are sown broadcast; while corn, pulse, and broad-leaved plants grown for their roots or leaves are sown in drills or rows. The term is sometimes applied to planting, but it is more generally restricted

BROADSIDE

Broadside. In Printing, any large page printed on one side of a sheet of paper. Modern broadsides are of various sizes, sometimes consisting of several sheets, which, when put together, frequently cover a great space. The letters used in the largest are often two or three feet in length, each one occupying a whole sheet. Old English broadsides are frequently valuable as illustrating the history of the period.

Brochantite. A native sulphate of copper has been thus named after Brochant the French mineralogist.

Broken-backed. A ship is said to be broken-backed when, in consequence of being loosened from age or injury, her frame droops at either end.

Broken-winded. A ruptured state of the air-cells, chiefly on the edges of the lungs, in the horse, in consequence of which the expiration occupies more time than the inspiration of the air, and is laboriously and generally spasmodically effected. It is a disease which may admit of palliation, but not of cure; the animal becomes gradually less capable of exertion, and if urged on, he drops and dies.

Broker (a word of doubtful origin). In Mercantile Law, a person employed in contracting for the disposal of property without being put in actual possession of it, as is the case with a factor. [FACTOR.] But all agents answering to this definition are not brokers, nor has the term any very exact legal significance. Particular classes of brokers are: bill or exchange brokers, stock brokers, insurance brokers, pawnbrokers, and brokers who sell or appraise household furniture for rent. By 8 & 9 Wm. III. c. 20, brokers in the city of London must be licensed by the mayor and aldermen, and grant a bond with a penalty of 500*l.* on their admission. According to mercantile usage, if goods within the city of London are sold by a broker to be paid for by a bill of exchange, the vendor, if not satisfied with the solvency of the purchaser, has a right within a reasonable time to annul the contract.

Brokerage. The percentage paid to the broker for his trouble in effecting a sale, or in negotiating any particular business.

Bromal. An organic compound consisting of *Aldehyde* in which three equivalents of hydrogen are replaced by chlorine. It is an oily liquid of unpleasant odour.

Bromargyrite. Native bromide of silver. [BROMYRITE.]

Bromeliaceæ (Bromelia, one of the genera). A natural order of Endogenous plants inhabiting the tropical parts of the world, where they grow in the rich vegetable soil of forests, or upon the branches of trees, to which they cling by their twisting slender roots. They usually have hard leaves, which are covered with a scurfiness easily rubbed off, and are so arranged as to be able to hold the water that drops in their centre. Many of them will grow in a moist soil, and flower, when propagated in a

BRONCHOTOMY

air, after being severed from their roots. Their flowers are usually white, crimson, blue, or purple, and often exceedingly handsome. In the genus *Ananassa* the bracts and flowers are so fleshy, that they all grow together into a solid mass, and thus form the well-known fruit called the Pine-apple. *Tillandsia usneoides* is a curious species of this order, hanging down in long grey threads from the branches of trees in American forests, and so seldom flowering that it might be taken for some species of lichen; it is easily dried, and then used for stuffing mattresses, &c. *Bromelia Pinguis* is a remedy against worms, and yields a cooling fever drink; and other species of *Bromelia* supply valuable fibre for textile purposes.

Bromine (Gr. *βρῶμος*, a strong odour). An undecomposed substance discovered in 1826 by M. Balard of Montpellier. In its general chemical habitudes it much resembles chlorine and iodine, and is often associated with them. It exists, but in very minute quantities, in seawater, and in the ashes of marine plants. It is usually extracted from *bittern* by the agency of chlorine. At common temperatures it is a very dark reddish brown liquid, of a powerful and suffocating odour, and emitting brown vapour. Its specific gravity is about 3. It boils at 116° and congeals at 4°. The density of its vapour is 5.6; 100 cubic inches at mean temperature and pressure weighing 167.25 grains. It is an electro-negative; it has bleaching powers, and is very poisonous. Its equivalent number is about 78: it combines with hydrogen to form *hydrobromic acid gas*, 100 cubic inches of which weigh 84.7 grains. With oxygen it forms the *bromic acid*. Its combinations are termed *bromides*; they have not hitherto been applied to any use, but some of them are probably possessed of powerful medical qualities.

Bromoform. A compound analogous to chloroform, but containing bromine in the place of chlorine. It is a heavy volatile liquid.

Bromyrite. Native bromide of silver. When pure it is of a yellow colour with a slight tinge of green. It is met with at Huelgoet in Brittany; also in Mexico and Chili, accompanying other ores of silver.

Bronchia (Gr.). The smaller ramifications of the windpipe.

Bronchitis (from Gr. *βρῆχτις*). Inflammation of the bronchia.

Bronchocele (Gr. *βρῆχκος*, the throat, and *κέλη*, a tumour). A tumour on the fore part of the neck, being a morbid enlargement of the thyroid gland. From its prevalence in Derbyshire, it is sometimes called the *Derbyshire neck*; and it is a very common disease among the inhabitants of mountainous districts, especially of the Alps. It has been attributed to some peculiarity of the water of those districts, but upon no satisfactory evidence. Iodine has been administered successfully in the cure of this and other glandular enlargements.

Bronchotomy (Gr. *βρῆχκος*, and *τομή*, I cut). The operation of making an opening into the windpipe in order to prevent suffocation.

BRONGNIARDITE

Brongniardite. A sulphide of antimony, silver, and lead; found in the mines of Mexico with Iron Pyrites, and named after M. Brongniart.

Brongniartine or Brongniartite. Native sulphate of soda, and lime. [GLAUBERITE.]

Brontozoum (Gr. *βροντή*, *thunder*, and *ζῷον*, *animal*). A genus of the large, apparently cursorial, fossil birds of the triassic deposits in the Connecticut valley has thus been called. It is only known by the gigantic footprints, some of which measure twelve inches between the tips of the inside and outside toes. The average length of stride, as shown by the distance between the impressions, was between three and four feet; the same limb was therefore carried out each step from six to seven feet forward in the ordinary rate of progression.

Bronze (Fr.). Bronze and bell metal are alloys of copper and tin in the proportion of 88 to 92 per cent. of the former, and of 8 to 12 of the latter; small portions of zinc or brass, and also of lead, are occasionally added. These alloys are harder and more fusible, but less malleable, than copper. The specific gravity of bronze exceeds the mean of its component metals when carefully hammered and free from air-blebs; but bronze castings are apt to be porous unless considerable care and skill have been used in fusing and pouring the metal, and in the construction of the mould; and in large castings, owing to the gradual cooling of the mass, there is often a want of uniformity in the composition of different parts of it; that portion containing the least tin being the first to solidify, while the more fusible portion to a certain extent separates, and is sometimes projected from the mould. In large bronze castings, such as statues, porosity and bubbles require carefully to be avoided: where they exist so as to deface the appearance of the work, they are sometimes filled up with substances which are only temporarily durable, or which, if metallic, give rise to electrical effects which time renders prejudicially evident. For this reason, the different pieces of a large statue should be fused together, or united by bronze, and not by a mere fusible solder; and iron bars and leaden junctions, for the support or fixing of the work, should, upon the same principle, be avoided, as they are themselves liable, under such circumstances, to corrosion, and this may affect the stability or safety of the statue, independently of other influences. Of the difficulty of casting a large and perfect bell in bronze, the Great Bell at Westminster has furnished a memorable instance.

Tempering produces upon bronze an effect directly opposite to that upon steel; and in order to render bronze malleable, it must be heated to redness and quenched in water. The alloy which thus acquires the greatest tenacity is that of 8 of copper and 1 of tin, and this is consequently preferable for medals; the advantage of bronze over copper for these purposes being hardness and resistance to oxidation: the former quality resists friction, and the latter

BRORA COAL

has handed down to us the works of the ancients with little deterioration, though buried for ages in damp soil or immersed in water. The small value of bronze, as compared with gold and silver, is also another important consideration, as affecting the preservation of such works of art. The alloy employed in the present bronze coinage is composed of 95 copper, 4 tin, 1 zinc. The pound avoirdupois is coined into 48 pence, each piece weighing 145·83 grains; into 80 halfpence, each weighing 87·50 grains; into 160 farthings, each weighing 43·75 grains.

Bronzing. This term is sometimes applied to the peculiar brown colour imparted to tea-urns, coffee-pots, and similar copper vessels, giving them a more agreeable appearance, and resisting tarnish and discolouration. This is effected by coating them with a film of suboxide of copper: the vessel is first cleaned, and then rubbed over with peroxide of iron (colcothar) made into a paste with a dilute solution of acetate of copper; in this state it is heated in a proper furnace or muffle, till it is found on brushing off the oxide that the surface beneath has acquired its proper hue. Medals may be bronzed in the same way.

Bronzing Liquid. A solution containing chloride of antimony and sulphate of copper, used for bronzing iron gun-barrels. Brass is sometimes bronzed by washing it over with a solution of chloride of platinum.

Bronzite. A variety of Diabase, with a pseudo-metallic lustre, frequently approaching to that of bronze (whence the name). It occurs in masses, with a lamellar structure inclining to fibrous, in the Serpentine of Cornwall; in the Syenite of Glen Tilt in Perthshire; in the Greenstone of the Isle of Skye; at Benenagh in Londonderry; also, in Styria, Piedmont, the Harz, &c.

Brookite. Pure native titanite acid, named after Brooke the crystallographer. It occurs in hair-brown, yellowish, or reddish crystals, which are more or less translucent, and have a brilliant lustre inclining to metallic, near Tremadoc in Caernarvonshire; at Tavistock; and in Perthshire. It has also been found in Dauphny, Savoy, the Urals, and at the Val del Bove, Etna. The opaque iron-black crystals from Arkansas have been named *Arkansite*. [ANATASE; ARKANSITE; RUTILE.]

Broom (A.-Sax. *brom*). The *Sarothamnus scoparius*, *Spartium scoparium*, or *Cytisus scoparius* of botanists, is an evergreen shrub, native of sunny soils throughout Europe. The Broom is sown extensively in this country as a shelter for game, and among the other plants in young plantations as a screen from the wind and a protection till the more important species can establish themselves. Its branches, which are tough, are made up into brooms, to which they have given their name.

Brooming of a Ship. [BREAMING.]

Brora Coal. Oolitic-coal fields are well known in various parts of Europe, Asia and America, and are in many cases valuable and productive. One of the oldest known workable

deposits of this kind was opened at Brora and its neighbourhood, on the north-east coast of Scotland, at the close of the sixteenth century, and is called the 'Brora coal.' Although not sufficiently good to compete with the coals of the regular coal measures, it is still an available fuel.

The Brora coal-field is chiefly interesting as the best of the small number of oolitic deposits of this kind in England. The coal lies with shales and sandstones; but like many of the small coal-basins of all ages, the various beds repose directly on granite without the intervention of other formations. Judging from its fossils, it belongs to the lower part of the oolitic series.

Brosimum (Gr. *βρώσιμος*, edible). A genus of *Artocarpacea*, consisting of South American trees, abounding in milky juice. They have large simple leaves; and the male and female flowers, which sometimes are produced on separate trees, are generally congregated into a globular head. *B. Alicastrum* yields the edible Bread-nuts of Jamaica; *B. Galactodendron* (sometimes called *Galactodendron utile*) is the Cow-tree or Palo de Vaca. The latter is a very tall tree, forming large forests. The milk is obtained by making incisions in the trunk, and so closely resembles that of the cow that it is used as an article of food, being wholesome, agreeable and nourishing.

Broussonetia (named in compliment to Broussonet, a French naturalist). A genus of Moraceae allied to the common mulberry, one species of which, the Paper Mulberry, *B. papyrifera*, furnishes a fibrous bark much used by the Chinese and Japanese in the manufacture of paper. It is a small tree, with deciduous leaves, of variable shape, mostly ovate, but sometimes divided into from three to four irregular lobes. The Pacific Islanders manufacture many of their garments from the bark of the Paper Mulberry.

Brown (A.-Sax. brun). In Painting, a dark dusky colour inclining towards red, of various degrees of depth, of which there are many sorts. It belongs to the tertiary colours, known as russets and olives, in which the hue is modified by an admixture of dark or black pigment.

Brown Clay Iron-stone. A variety of Brown Iron-ore consisting of anhydrous peroxide of iron with an admixture of argillaceous matter.

Brown Coal. A variety of Coal, distinguished from stone coal by its streak when scratched, which is brown and different from the black streak of coal. There are, however, two distinctions of greater importance than streak, affecting brown coal: one is that they deteriorate by exposure to the air, tending to split and fall to powder; the other, that they contain water, which interferes with their value as economic fuel.

As almost all the lignites belong to a more recent geological period than that called 'carboniferous,' they have been often spoken of as *modern coal*. They are, however, confined to

no age, many true lignites occurring in rocks much older than the tertiary period, while some tertiary rocks contain excellent stone coal.

Many of the lignites, or brown coals, so closely approach pit coal in appearance, that it requires an accustomed eye to detect any difference. Exposure to the air, however, soon settles the question, as the brown coal after about six weeks or two months falls into powder, whereas a good coal undergoes hardly any change. Experiments in getting up steam would tell the same story, as a much larger weight of brown coal than of pit coal is needed for the purpose.

The consumption of brown coal in countries where other fuel is scarce, is very large. Nearly 700,000 tons of it are officially reported as having been raised and sold in the Austrian dominions during the year 1861.

Brown coal appears to be more common in the great middle tertiary basins of Europe than elsewhere. It is especially abundant in the basin of the Danube and other deposits connected with the Eastern Alps and Carpathians, where its quality is very excellent. [LIGNITE; BOVRY COAL; KIMERIDGE COAL.]

Brown Iron-ore. A native hydrated peroxide of iron composed of 85.6 per cent. of peroxide of iron and 14.4 water; often with small percentages of silica, alumina, &c.

There are several varieties of this ore, which generally occurs in stalactitic, botryoidal, and mammillated forms, with a fibrous structure, a silky lustre and often a semi-metallic appearance: it is, also, sometimes earthy. [LIMONITE; BOG IRON-ORE; LAKE ORE; YELLOW OCHRE; BROWN AND YELLOW CLAY IRON-ORE; &c.] In colour it is of various shades of brown, and is distinguished from other ores of iron by a brownish yellow streak, free from any tint of red.

Brown Iron-ore is a valuable and abundant ore of iron, and occurs in several countries, diffused through many formations.

Brown Spar. A magnesian carbonate of lime, tinged by oxide of iron and manganese. The name is applied more especially to those varieties of brown crystallised Dolomite which contain carbonate of iron.

Brownists. In Ecclesiastical History, the followers of Robert Brown, who in the year 1581 established a sect upon the principle that every congregation should form a church independent (in matters of discipline and doctrine) of all others. In matters of doctrine he did not himself differ from the church: to which indeed he returned, and in which after some years he took preferment. The Brownists underwent great persecution under Elizabeth, and retired in considerable numbers to Holland. From them, however, have sprung the Congregationalists or Independents, a very powerful sect in England at the present day. [INDEPENDENTS.]

Bruchus. A Linnaean genus of Coleopterous insects, of the tribe *Rhynchophora*, now the type of a family (*Bruchidae*), with the following characters: upper lip distinct: head

BRUCIA

produced anteriorly into a broad flattened snout; palpi filiform; antennae filiform or serrate; eyes notched; wing-sheaths not covering the extremity of the body. The insects of this family deposit their eggs in the young grains or seeds of leguminous plants; the time of the hatching of the eggs is when the seeds have approached to maturity, and then the larvae begin to feed voraciously upon them. One species, the *Bruchus granarius*, infests our peas; and the ravages of this insect, and the *Bruchus pisi*, have been so extensive as to call for legislative interference: in France, for example, in the year 1780, the sale of peas in the market was prohibited, in consequence of the damaged and unwholesome condition of those vegetables through the operations of the species of *Bruchidae* above cited.

Brucia. A vegeto-alkaloid, discovered by Pelletier and Caventou in the bark of the *Brucia antidysenterica*; and also associated in small relative proportion with *strychnia* in the nux vomica and St. Ignatius's bean. It is very bitter and poisonous.

Brucite. The name given by Cleaveland to Chondrodite, in honour of Prof. Bruce of New York, by whom the mineral was first described. The name is, however, commonly applied to native hydrate of magnesia. This salt, which is composed of 68·97 per cent. of magnesia, and 31·03 water (the magnesia being sometimes partly replaced by iron), usually occurs in fibrous or foliated masses. [NEMALITE.] It is white, inclining to grey, blue, or green, with a pearly lustre, and is more or less translucent.

The Brucite found, in the Shetlands, forming veins in Serpentine at Swinansess in Unst, occurs in aggregated foliated plates of a silvery-white colour, and translucent. Amongst other localities it is chiefly met with at Pyschmink in the Ural, Hoboken in New Jersey, Pennsylvania, Texas (*Texasite*), &c.

Bruniaceæ (Brunia, one of the genera). A small family of epigynous Exogens closely related to the *Hamamelidaceæ*, and of botanical interest only.

Brunner's Glands. These glands, so called after their discoverer, are minutely lobulated bodies, situated beneath the mucous membrane in the tissue of the duodenum: they are provided with permanent gland-ducts, which pass through the mucous membrane and open on the internal surface of that intestine.

Brunolic Acid. A brown vitreous substance contained in the distillate of coal tar.

Brunoniaceæ (Brunonia, the only genus). A small family of perigynous Exogens belonging to the Echioal alliance, and consisting of an almost solitary species of Australian herb, named after Robert Brown, the eminent English botanist.

Brunswick Green. A pigment obtained by exposing metallic copper to the action of muriate of ammonia. It is a compound of chloride and oxide of copper. It is also generated by the action of sea-water upon copper, as

BUBALUS

in the green matter which incrusts the copper sheathing of ships.

Brush. In Painting. [PENCIL.]

Brush Ore or **Black Brush.** A local term applied in the Forest of Dean, in Gloucestershire, to a stalactitic Brown Iron-ore found hanging from the roofs of caverns, and also in large quantities in the 'sandstone' and 'limestone vein' of the lower carboniferous rocks of that locality.

Bruta (Lat.). The term by which Linnæus designated an order of Mammals, including the elephant, manati, and walrus, with the quadrupeds now forming the order *Edentata* of Cuvier.

Bryaceæ (Bryum, one of the genera). A natural family of Mosses of the acrocarpous group, distinguished by their capsules having a double row of teeth, the inner of which are united at the base by a common plicate membrane. The name is sometimes applied to all the true Mosses.

Bryonine. A bitter poisonous principle, extracted from the root of the *Bryonia alba*.

Bryony (Gr. *βρύων*). The *Bryonia dioica*, a wild climbing plant belonging to the Cucurbitaceous order. It has a large woody perennial root, and annual stems, which resemble those of a gourd, except that they are more slender, clinging to bushes by means of their twisting tendrils. As its name implies, it is diœcious. The berries are scarlet, with a disagreeable odour when bruised. The leaves have five angular lobes, and are three or four inches broad, with many callous tubercles. The roots are violently purgative.

Bryozoa (Gr. *βρύον*, moss; *ζῶον*, animal). An order of compound polypes, including the *Flustra* or sea-mat, which incrusts foreign bodies like moss. The organisation of the individual polypes resembles that of the Ascidian molluscs.

Bubalus (Lat.; Gr. *βούβαλος*, a term originally applied to a species of antelope; but afterwards transferred, in the age of Martial, to different species of the ox). A genus of Bovidae which is formed by the buffaloes of India and Africa (*B. buffelus*, *B. Arni*, *brachyceros*, and *Caffer*), the musk buffalo of North America (*B. moschatus*), and the anoa (*B. depressicornis*) and *taxicolor*. Fossil evidences of the musk buffalo have been found in pliocene deposits at Maidenhead (Berks). The genus *Bubalus* includes those species which have the bony core of the horn excavated, with large cells or sinuses communicating with the cavity of the nose; the horns are flattened, and bend laterally with a backward direction, and are consequently less applicable for goring than in the Bisons, or Taurine group of oxen; the head is large, with a narrow but convex forehead, and terminates in a broad muzzle. The Buffaloes are of large size, but low in proportion to their bulk; they have no hump on the back, and only a small dewlap on the breast: the hide is generally black: the tail long and slender. The Buffaloes occupy

BUBO

the warm and tropical regions of the earth; they avoid hills, and prefer the coarse vegetation of the forest and swampy regions to that of open plains; they love to wallow in water; they swim well, and cross the broadest rivers without hesitation; their gait is heavy, and they run almost always with the nose horizontal, being principally guided by the sense of smell. The Arnee Buffalo (*Dos Arni*) is the species in which the horns attain the greatest size: there is a pair of horns in the British Museum considered by Colonel Smith to be of the true or Great Arnee: each of these horns measures along the curve from base to tip, six feet three inches; circumference at the base, eighteen inches.

Bubo (Gr. *Βουβών*, *the groin*). A tumour very frequently occurring in the glands of the groin, and also in the armpit. It is often the result of local absorption of irritating matter, as in venereal buboes; or is symptomatic of constitutional disease, as in the plague, scrofula, and some fevers.

Bubonocoele (Gr. *Βουβών*, *the groin*, and *κῆλη*, *tumour*). A rupture forming a tumour in the groin.

Buccaneers (Fr. *boucanier*, from *boucan*, a word of the Carib Indians signifying a place for feasting on meat which was smoked and cooked at the same time; hence those who established themselves on the West India islands for the purpose of smoking meat were called buccaneers: Wedgwood, *Dictionary of English Etymology*). The pirates who infested the coasts of the West Indies and South America during the seventeenth and eighteenth centuries were so called. The association of these pirates is said to have commenced as early as the middle of the sixteenth century; but in 1625 they obtained possession of St. Kitt's, and afterwards of Tobago, which thenceforward became for a long time the head-quarters of the buccaneers, who formed a sort of seafaring republic, composed chiefly of English and French adventurers. Their chief object was war against the Spaniards, and plunder of their ships and settlements. After the peace of Ryswick, in 1697, they gradually disappeared from the seas. The *History of the Buccaneers of America*, by James Burney, is a well-known and entertaining work. By French writers these pirates are commonly called *Flibustiers*, apparently a corruption of the English word *freebooters*.

Buccinator (Lat.). A muscle of the cheek called into action in various motions of the mouth, and especially in blowing a wind instrument.

Buccinum (Lat. *a trumpet or shell-fish* so called). The name of a Linnæan genus of Vermes Testacea, characterised by having a shell with a smooth non-plicated columella, and with a fissure or short respiratory canal inflected towards the left. The mollusca with shells corresponding to this character are ranked amongst the Pectinibranchiate Gastropods by Cuvier, and have been subdivided into the following sub-

BUCKWHEAT

genera: *Buccinum* proper, Brug., of which the wheek, *Buc. undatum*, is an example; *Nassa*, Lam.; *Eburna*, Lam.; *Ancillaria*, Lam.; *Dolium*, Lam.; *Pardis*, Mart.; *Harpa*, Lam.; *Purpura*, Brug.; *Monoceros*, Lam.; *Ricinusula*, Lam.; *Concholepas*, Lam.; *Cassia*, Brug.; *Morio*, Montf.; *Turbera*, Brug.

Bucco (Lat. *bucca*, *chuck*). The name of a genus of Zygodactyle birds, called Barbets. The scientific term relates to the tumefaction of the sides of the base of the bill; the trivial English name is derived from the bristly feathers which surround the base of the bill, and project beneath the chin like a beard. The genus is now the type of a family, including the Barbets proper (*Bucco*), the Brazilian barbets (*Tamatia*), and the Barbicans of Buffon, which are limited to the warmer parts of India and Africa.

Bucentaure (Gr. *Βούς*, *an ox*; *κένταυρος*, *a centaur*). A mythological monster, half-man and half-ox, as the Greek etymology of the word imports. This was also the name of the state galley of the Venetian doges, in which they annually sailed over a portion of the Adriatic on Ascension Day, and dropping a ring into the sea, espoused it in the name of the republic, with the words, 'Desponsamus te, mare, in signum veri perpetuæque dominii.'

Buceros (Gr. *Βουκέρως*, from *Βούς*, and *κέρας*, *a horn*). A genus of Syndactylous Insectorial birds, remarkable for the prodigious size of the mandibles, of which the superior in some species supports a large horn-like protuberance. The birds of this genus are commonly called horn-bills; they are peculiar to the Old World, and perform the same offices in wild nature as the toucans of America.

Bucholzite. A variety of Sillimanite (named after the German chemist, Bucholz), of a whitish, greyish, or pale brown colour, with a lustre approaching to adamant. It is a sesquioxide of alumina, and is found in fibrous masses, sometimes approaching distinct prisms at Passa-thal in the Tyrol, at Chester on the Delaware, and at other places in the Northern States of America.

Bucka or **Buchu**. A strong-smelling leaf imported from the Cape of Good Hope, and used medicinally as a tonic in affections of the kidney and bladder. It is produced by *Baryosma* or *Diosma crenata* and some allied species.

Bucking. The washing of linen with weak alkaline leys, in the operation of bleaching.

Bucklandite. A variety of Pistacite (named after Dr. Buckland), bearing much resemblance to Augite. It has been found at Arendal in Norway, in the lavas of the Laacher-See on the Rhine, and at Achmatowsk in Siberia.

Buckwheat (a corruption of beechwheat). A kind of grain, produced by the *Fagopyrum esculentum* of botanists. It has a triangular form, not unlike that of beechmast, but small. In some countries it is cultivated as food for man, and even in this country its flour is said to enter into the composition of the thin cakes called crumpets; but its chief value is as food

for pheasants, which are so fond of it that they may be decoyed from their preserves by its employment. It is said that some estates have been rapidly stocked with this description of game, at the expense of the neighbouring coverts, by the aid of a few fields of buckwheat. It is a good healthy corn, and may be grown on poor light soils. A bushel of seed per acre is now broadcast in May. The plant was formerly and is now sometimes included in *Polygonum*.

Bucolles. The Greek term for pastoral poems, meaning literally the songs of herdsmen (*Βοῦκοι*). To this class belong the poems of Theocritus, Bion, and Moschus, and the Eclogues of Virgil. The metre universally employed is the hexameter or heroic; but in pastoral poetry an easier flow of the lines was studied than in epics, and this was generally accomplished by introducing a larger proportion of the metrical feet called dactyls in the former than in the latter. This species of poetry has been cultivated also by most modern nations, and in England, France, and especially in Germany, with great success.

Buddhism. A religion which prevails over a great part of Asia; and, according to the estimates of some geographers, has a much greater number of worshippers than any other form of faith among mankind. China, the peninsula beyond the Ganges, Japan, Ceylon, and various Indian islands, are chiefly peopled by Buddhists. The founder of this religion, according to tradition, was an Indian prince, to whom the title of Buddha, or 'The Enlightened,' is assigned by his worshippers. The time at which he lived is uncertain. The Brahmans would, of course, pay no attention to his life or death, nor could any reference be made to either for chronological or other purposes till the time of Asoka, who established Buddhism in India in the third century B.C. (Max Müller, *History of Sanskrit Literature*, p. 264 &c.; see also Barthélemy de St. Hilaire, *Le Buddha et sa Religion*.) Buddhism was expelled from India by the persecutions of the Brahmans, between the fifth and seventh centuries of our era. The doctrines of the Buddhists seem mainly to rest on the principle, that the world, and sensible objects contained in it, are manifestations of the Deity, but of a transient and delusive character; that the human soul is an emanation from Deity; that after death it will again be bound to matter, and subjected to the miseries and accidents of this life, unless the individual to whom it belongs succeeds by the attainment of wisdom, through prayer and contemplation, in liberating it from that necessity, and secures its absorption into that divine essence from which it sprang. [MONACHISM; UPADĀRA.]

Bude Light. This term has been applied to various forms of oil and gas burners contrived by Mr. Gurney, of Bude, in Cornwall. The original proposal was to maintain the combustion by means of a supply of oxygen gas to the burner, by which, with oil or naphthalised gas, an intense light may be com-

manded, but at an inconvenience and expenditure quite incompatible with its economical adoption. Large gas burners with variously formed reflectors and refractors have since been erected in different parts of London under the name of *Bude Lights*, but they have nothing in common with the original proposal.

Budget (Fr. *bougette*, Ital. *bolgetta*). In a general sense means a condensed statement of the income and expenditure of a nation, or of any particular public department. In this country, the Budget is annually brought forward by the Chancellor of the Exchequer, who in his speech gives a general view of the public revenue and expenditure, and intimates whether government intend to propose the imposition or repeal of any taxes, &c.

Buff Leather. A leather prepared by imbuing the prepared skin with an aluminous compound, and afterwards some oily matter, such as yolk of egg.

Buffalo. [BUBALUS.]

Buffers. Elastic cushions attached to railway carriages for the purpose of breaking the shock when one carriage is pushed against another. They are usually formed of horsehair covered with leather; but may consist of strong iron springs, or of vulcanised caoutchouc.

Buffy-coat. When the coagulation of blood is retarded so as to allow the red particles to sink, and the lighter white corpuscles to rise towards the surface, the supernatant opaline plasma coagulates without the red particles, but includes the white ones, and forms a light-coloured clot of fibrine and white corpuscles resting upon the main body of the coagulum which has included the red corpuscles, and constitutes what is called the 'buffy-coat.' It is indicative of inflammatory disease, during which the coagulation of the blood is retarded beyond the ordinary time.

Bug. [CIMEX.]

Bugle Horn (from *bucula*, a *húifer*). A musical wind brass instrument, latterly improved by keys, so as to be capable of all the inflections of the scale.

Buhl. [BOULE.]

Building Materials. These may be divided into calcareous, silicious, argillaceous and porphyritic. Of the first are limestones and marbles; of the second, sandstones; of the third, brick-clay and slates; and of the last, granites.

Limestones afford an excellent building material where they can be obtained on or near the spot where they are needed. Some are good enough and of sufficient repute to be worth carrying to a distance.

The best limestone for building purposes in England is Portland: a white and durable stone, obtained from numerous quarries in the Isle of Portland. These beds are among the upper members of the oolitic series. Cheaper and inferior, but valuable stones are obtained from quarries near Bath. These are called

BUILDING MATERIALS

Bath stone: they are of a warmer tint, softer, more absorbent, and lighter than Portland; but the best kinds are inferior to the best kinds of Portland. The Bath stone is from the upper part of the lower oolite. Very large quantities of excellent material are obtained from the lower oolites of Northamptonshire. The magnesian limestones on the borders of the coal measures in Derbyshire, Nottinghamshire, and the south of Yorkshire are locally valuable, and widely used. Varieties of chalk are sometimes employed for internal work, especially in cathedrals and churches.

Some of the foreign limestones and oolites are also used in England. Of these the Caen stone is the most remarkable. It is not unlike Bath, but the best kinds are harder and more durable.

Many limestones are durable when weathered to some extent before being exposed to the atmosphere of large towns; but few can stand that test without preparation. The magnesian limestone that has been so much animadverted on in reference to the Houses of Parliament, does not decompose in its own atmosphere, though unable to withstand that of London. A study of country churches and tombstones is therefore insufficient to justify an opinion as to the durability of limestone.

Sandstones are valuable building stones; some of the coal grits being of good colour, moderately hard, compact, and durable. Others decompose readily, especially if placed carelessly in a building. Craigleith stone from near Edinburgh is one of the most durable of these stones; and that of Darley Dale is also good. The value of sandstone for building purposes depends much on the cementing medium; where that is marly or calcareous there is little hold, but where it is silicious it is generally durable. Laminated sandstones, with green or red wavy lines, are rarely valuable. Grey stones with a moderate amount of mica are often very tough, and valuable for flags and paving as well as for building.

The granitic and porphyritic rocks are only economical where there is no other material at hand. They are difficult and costly to dress, even to the roughest shape, but they are very durable. The better kinds when polished are beyond all comparison the best materials for monumental purposes; but even granites need careful selection; some kinds, although tough and expensive to work, are liable to disintegration.

Marbles are generally durable in a dry atmosphere; but the fine white crystalline kinds are too costly for general use. The coloured marbles found in England are rarely employed for external work; but the compact semi-crystalline limestones of the carboniferous system are almost as beautiful and much cheaper.

Slates and slabs are of great value for constructive purposes, but chiefly for roofing and paving. They are now also largely used for internal work. [SLATES.]

BULL, GOLDEN

Common clays are the minerals used in the manufacture of brick. Their value depends on various circumstances. [BRICK CLAY.]

Among constructive materials the various cements should be mentioned. They will be found described in another article. [CEMENT.] There are also some excellent kinds of artificial stone, which are elsewhere noticed. [STONE, ARTIFICIAL.]

Bul. The name of the eighth month of the ecclesiastical year of the Jews (1 Kings vi. 38).

Bulb (Lat. *bulbus*, Gr. *βολβός*). In Botany, an organism formed of a collection of fleshy scales, arranged like those of a bud, of which the bulb is a modification. It is usually found underground, as in the hyacinth; but sometimes in the axils of the leaves, as in some lilies. The old botanists used to distinguish two sorts of bulbs, the tunicated and the solid, but the former is the only one to which the name is now applied. The so-called solid bulb is the corm, as found in *Crocus*.

Bulbodium. A kind of underground stem resembling a rhizome.

Bulbogemma. A name for those bulbs which grow on the stems of plants, as in the tiger lily and other species of that genus.

Bulbotuber. That kind of stem which the old botanists called a solid-bulb, and the moderns more generally a corm. It is a solid underground stem, generally round or roundish, clothed with the withered remains of leaves, and producing buds on its surface, as in *Crocus*.

Bulbus Arteriosus. In Embryology, the third cavity developed upon the primitive arterial trunk; the first being the auricle, the second the ventricle. The trunks of the aorta and pulmonary artery are developed out of the bulbus arteriosus in the warm-blooded vertebrata. In Comparative Anatomy the muscular basis of the branchial artery in fishes is so called, which may be regarded as a retention of the embryonic structure by arrested development.

Bulgeways. Are timber supports placed beneath the sides of a ship while building, and which furnish a steady power during launching. They slip along the ways of the dock, and separate by the action of floating as soon as the vessel's hull has plunged into the water.

Bulimia (Gr. *βουλμία*, literally *ox-hunger*). A morbid appetite for food.

Bulkhead. The sea term for any partition, as of wood, canvas, or other material. Modern steamers for ocean traffic are rendered additionally safe by being divided into several compartments by means of water-tight bulkheads.

Bull, Golden. In German History, a term applied particularly to a statute or enactment of the emperor Charles IV., published A.D. 1356, in two diets held in succession at Nuremberg and Metz, for the purpose of fixing the laws in the election of the emperor, and of regulating the number and privileges of the electors (Churfürsten). The original copy of

BULL, PAPAL.

this instrument is preserved at Frankfort-on-the-Maine, and has a seal of gold appendant; whence the appellation Golden Bull is derived. (Milman, *History of Latin Christianity*, book xii. ch. xi.)

Bull, Papal (Lat. *bullā*). An instrument, ordinance, or decree of the pope, equivalent to the proclamations, edicts, letters patent, or ukases of secular princes. Bulls are written on parchment, to which a leaden seal is affixed, and are granted for the consecration of bishops, the promotion to benefices, and the celebration of jubilees, &c. The publication of papal bulls is termed fulmination; and it is done by one of three commissioners, to whom they are usually addressed. The seal or 'bull' is thus described by Matthew Paris, anno Dom. 1257: 'In bulla domini Pape stat imago Pauli a dextris crucis in medio bullæ figurate, et Petri a sinistris.' Bulls are generally designated by the first words of their text: thus, the bull *Unigenitus*, or *In cæna Domini*, &c. [BULLA.]

Bull's Eye. In Architecture, the technical name given to a description of glass lens used for the purpose of concentrating the light of a given centre upon an object; it is also applied to a circular window of plain glass.

Bull's Nose. In Architecture, the external angle of a polygon, or of two lines which meet at an obtuse angle.

Bulla (Lat.). A stud or boss, but more particularly an ornament in the shape of a heart, worn round the neck by noble Roman children till they were seventeen years old, when they assumed the manly dress of the toga, and suspended the bulla as a consecrated offering to the *lares* or household gods.

BULLA. A genus of Acerous Gastropodous Molluscs, the shell of which is more or less globose, or inflated like a bubble; having a spire not visible or projecting, but concealed by the large external whorl, which is elevated above the rest. The columella makes a convex prominence, which gives a crescentic form to the aperture of the shell. The animal breathes by gills, but has no respiratory tube or siphon, and consequently the margin of the aperture of the shell is entire, or without a fissure or canal. All the species of bulla are remarkable for a shelly apparatus of three pieces which converts the stomach into a gizzard or triturating cavity. These gastric calcareous pieces have been described as a bivalve shell of a new genus.

Bullet. The projectiles fired from small arms only are called bullets. The bullet for the Enfield rifle now in use in the service is .65 inch in diameter, 1.0625 inch in length, and weighs 530 grains. It is elongated, and has a small boxwood plug fitting into a hollow at its base, which, receiving the first shock of the explosion, is driven forward into the bullet, causing the lead to bulge out, and thus fit the bore tightly, and fill the grooves.

Bulletin (Fr. from Mod. Lat. *bulleta*). In Diplomats, a term equivalent to schedule, and variously applied to different public acts.

BUNTER SANDSTEIN

In modern times, this name has been applied, especially in France, to reports of a state of facts issued by authority; as bulletins of health, bulletins of military events, &c.

Bullion (Fr. *bouillon*). Uncoined gold and silver. The word originally meant the mint or office where the precious metals were reduced to the proper alloy and converted into stamped money. For the history of the word, see Wedgwood, *Dictionary of English Etymology*.

Bulwark (Dutch, *bolwerck*, a rampart made of holes or trunks of trees; Wedgwood). On Shipboard, is the parapet raised round the deck for the purpose of protecting men and goods from slipping overboard, and at the same time for protecting the deck from the waves. In ships of war the bulwark is of considerable solidity and height, to afford the crew cover from an enemy's small shot. The hammocks are ordinarily stowed in the bulwark during the day.

Bumelo. A glass flask of flattened ovoid shape, in which camphor is sublimed.

Bumboat. A boat allowed to attend a ship to supply the sailors with articles of provisions, clothing, &c.

Bumkin (perhaps a diminutive of *boom*: Ger. *baum*, a tree, also a beam). On Shipboard, is a short boom fixed on each side of the bow for the purpose of stretching the foresail farther to windward than the width of the deck at that part permits. It has a strong block at the end, through which the tack of the sail is worked.

Bunt. A parasitic fungus, called *Tilletia caries*, having globose spores with a cellular outer coat, in which it differs from other *Ustilagines*, the group of *Pungis* to which it belongs. It often inflicts great damage on wheat. According to Mr. Berkeley, the best remedy is to wet the seed corn thoroughly with a strong solution of Glauber's salts, and then dust it with quicklime.

Bunt Lines. In Navigation, used for gathering up the centre part of a square sail.

Bunt of a Sail. Is that portion nearest the central perpendicular line. If a sail be divided into four equal portions, from side to side, the bunt would comprise the two central strips.

Bunter Sandstein. The German designation, imported into English Geology, of the lower portion of the Triassic series as developed in Central Europe. It consists there of compact sandstones overlaid by fissile and incoherent beds. Large quantities of this deposit flank the Vosges mountains, covering the *grès de Vosges*, or lower new red. In England there is often little distinction between the Bunter sandstein or lower and the Keuper or upper member of the TRIAS, owing to the absence of the calcareous middle member or MUSCHELKALK. A conglomerate bed forms the usual upper member of the Bunter, and certain stones called *waterstones* the base of the Keuper.

The Bunter sandstein is known in French Geology as the *grès bigarré*. It is there generally a fine-grained solid sandstone, useful as a

building stone. Its colour is sometimes white, but more frequently of a blue, red, or greenish tint. Some of the intermediate beds make good millstones. In some districts the Bunter sandstein contains many fossil plants. In other respects fossils are very rare.

Buoy (Dutch *boei*, Fr. *bouée*, Span. *boya*). A floating body formed of wood, and very often of hollow iron, moored over a certain spot, to indicate the situation of a shoal or sand bank, and to mark out the course a ship is to st

When used for this purpose, buoys are usually close vessels in the form of a cone, of large dimensions, in order that they may be seen from a distance; and generally painted of some particular colour, so as to be readily distinguished from one another. Public buoys in this country were placed by warrant of Queen Elizabeth under the management of the Corporation of the Trinity House, and the amount of revenue annually collected for their use is between 11,000*l.* and 12,000*l.* Small iron buoys are used for the purpose of indicating the situation of ships' anchors (to which they are fastened by a rope), in order that the ship may be prevented from running foul of the anchor, and that the anchor and cable may be recovered when the latter has been broken or cut.

Buphaga (Gr. *Bouphagos*). A genus of Conirostral Passerine birds, of which the African beef-eater (*Buphaga africana*) is the sole example. It derives its name from its habit of sedulously extracting from the backs of cattle the larvæ of æstri and other Dipterous insects which are deposited therein.

Buprestis (Gr. *Bouphragis*, from *πρῆσθω*, to swell). The name of a Linnæan genus of Coleopterous Soricorn insects, now the type of a family (*Buprestide*), including the most splendid and brilliant beetles. Of this family upwards of a thousand species are known; by the French they are termed 'Nichards.'

Buratite (named after M. Burat). mineral found in Calamine at Loktetskoi in the Altai, at Chessy near Lyons, &c. It is a hydrated carbonate of zinc, copper, and lime, and it occurs in radiating acicular crystals, of a verdigris-green colour.

Burden (Fr. *bourdon*, a staff). In Music, the drone or bass in some musical instruments, and the pipe or string that plays it. The bass pipe in the bagpipe is so called. Hence, that part of a song that is repeated at the end of every stanza is called the burden of it.

Bureau (Fr.). Originally a writing table; afterwards applied to the office of any public or private functionary where business is transacted.

Bureaucratic or Bureaucracy. Is the system by which the business of administration is carried on in departments, each under the control of a chief, in contradistinction to those systems in which the officers of government have a coordinate authority.

Burette (Fr.). An instrument occasionally used in the chemical laboratory, and in the assay office, for the purpose of dividing a given

portion of any liquid into 100 or 1,000 equal parts.

Burg-grave (Ger. *burg-graf*). In the German Empire, a castellan or lord of a castle, having the right of private justice, imposing taxes, &c.

Burgage Tenure. In Law, an ancient tenure proper to boroughs; under which tenements are held of the king, or other person, at a rent certain. In several boroughs such holdings conferred the electoral franchise previous to the Reform Act.

Burgee. In Nautical phraseology, is a flag which ends in two points.

Burgh Mote (borough meeting). An Anglo-Saxon term for the borough court. *Burgh mote* is the title of a court of miners, held in Derbyshire.

Burghbote. In the old English laws, was an impost levied for the raising or repairing of the defences of a borough or city.

Burghers and Antiburghers. In Ecclesiastical History. Owing to an undue exercise of patronage, which took place under the authority of the church of Scotland, or to the induction of a clergyman into a parish (Kinross) against the declared sentiments of the congregation, a schism took place in the church, which occasioned a secession from that establishment, and ultimately led to what is called the Burgher and Antiburgher denominations. Certain deposed clergymen constituted themselves into an ecclesiastical court, called the *Associate Synod*. To the deposed ministers and their adherents the name of *Seceders* was applied; and hence the origin of the *Secession Church* in Scotland. In 1745, they formed themselves into a synod, which consisted of three different presbyteries. But shortly afterwards they divided on the question of the lawfulness of an oath commonly administered to burgesses in towns. This dispute, which commenced at the meeting of the Synod in 1745, continued to be maintained with increasing acrimony for two years, or till 1747. The party that were in favour of the oath were called *Burghers*; the party that opposed it were termed *Antiburghers*. The latter finally withdrew in a body; Mr. Mair, one of their number, having previously protested that 'hereby the Burghers had forfeited all their synodical powers, and that the whole power of the Synod devolved on himself and his party and such as came to them.' Next day, the Antiburghers held a synod composed exclusively of their own adherents, twenty-two in number, including ministers and elders, and constituted themselves into a distinct and separate sect of Christians. (Brown's *Hist. Acc. of the Rise and Progress of the Secession*.)

The chief practical difference that obtained between the church of Scotland and the Seceding bodies consisted in the one cleaving to patronage, and in the other having abolished that system, and introduced popular election in its stead. Besides, though the church has always been governed by kirk sessions, presbyteries, synods,

BURGLARY

and a general assembly, the Burghers and Antiburghers, owing to the comparative paucity of their numbers, never adopted a general assembly. With them the synod was the supreme court, whose authority was final in all religious and ecclesiastical matters. The Seceders also were stricter Calvinists, and adopted more rigid discipline as to admission to church membership and *sealing ordinances* (baptism and the Lord's Supper) than the church party had perhaps ever done. (*Ib.*)

In 1820 the two bodies became reunited, and assumed the denomination of the *United Associate Synod of the Secession Church*. At that time, the Burgher persuasion comprehended 10 presbyteries, embracing 120 congregations; and the Antiburghers 11 presbyteries, consisting of 141 congregations. Since their union, their conjoint influence and extension have been considerably on the increase; in 1859 the 'United Presbyterian Church' counted 528 congregations: and it was said that a fifth part of the population of Scotland was connected with it. (*M'Culloch's Stat. Acc. of the British Empire*, ii. 425-7.)

Burglary (Low Lat. *burgi latrocinium*, robbery committed in a *burg* or fenced place). In Law, is the breaking and entering the dwelling-house of another in the night time, with intent to commit a felony. This offence is punishable by penal servitude or imprisonment.

Burgomaster (Ger. *bürgermeister*, chief of the citizens). The usual title of the chief municipal officer in German and Dutch towns. In the German free cities, the president of the executive council is styled *bürgermeister*; but in many towns of importance, the title *stadtdirector* (town-governor) has been recently substituted in its stead.

Burlesque (Fr.; Ital. *burlesco*, from *burlare*, to jest). The Italian *poesia burlesca* signifies merely comic or sportive poetry; but the term, in French and English, is more commonly restricted to compositions of which the humour consists in a ludicrous mixture of things high and low, as high thoughts clothed in low expressions, or, vice versa, ordinary or base topics invested with the artificial dignity of poetic diction. The humour of parody or travesty [*PARODY*] arises from the burlesque. *Burletta*, a slight comic musical drama, is derived from the same origin.

Burmanniaceae. A small natural order of Endogens, related to Orchids.

Burnet. A British plant, whose leaves have been used as food for sheep. It grows on poor calcareous soils, where few other plants will succeed, and in this its principal value consists; it is moreover perennial, and remains green all the winter. It is the *Poterium Sanguisorba* of botanists.

Burning Glasses and Burning Mirrors. The name given to glasses or mirrors so formed as to collect the sun's rays which fall on them into a point or small surface, and thereby produce an intense heat, and set fire to combustible substances. The point at which the rays meet,

BURNING GLASSES

and where the greatest heat is produced, is called the *focus* or *burning point*. The rays of light or heat may be concentrated either by refraction or reflection: in the former case they must pass through a transparent refracting substance, as glass formed into a proper shape; in the latter they fall on a concave polished surface of silvered glass or bright metal. Reflectors made of glass are usually termed mirrors, those of metal *specula*.

The method of exciting heat or producing fire by the concentration of the sun's rays was known from remote antiquity; but the most famous recorded achievement of this kind is that of Archimedes, who is reported to have burned by means of mirrors the Roman fleet in the harbour of Syracuse. Considerable doubts have prevailed respecting the truth of this statement, chiefly grounded on the circumstance that although the setting fire to the fleet is positively affirmed by Dion, Diodorus Siculus, Pappus, and others, no mention is made of it by Livy, Polybius, or Plutarch, who are otherwise minute in detailing the mechanical contrivances of Archimedes, and who were not likely to pass over so notable an occurrence without notice. Descartes went so far, indeed, as to treat the whole relation as fabulous, affirming the thing to be impracticable. Its practicability was, however, experimentally demonstrated by the celebrated Buffon, who, by a combination of plane reflecting mirrors, produced results which must be regarded as of still greater difficulty. With 168 mirrors, each about six inches square, he set fire to planks of beech 150 feet distant, and this with the faint rays of the sun at Paris in the month of March. It is not necessary to suppose that Archimedes could not place his apparatus within that distance of the fleet of Marcellus; besides, by multiplying the number of mirrors, the concentration of the rays may be increased almost to any extent. All this, however, does not prove the actual fact related of Archimedes. Buffon, with all the resources afforded by the advanced state of the arts in the middle of the eighteenth century, and after a number of experiments, succeeded, with considerable difficulty, in constructing an apparatus by means of which he could inflame combustible substances at a considerable distance. The low state of the arts in the time of Archimedes must have rendered the undertaking considerably more difficult. The silence of those historians who have detailed his other mechanical contrivances can hardly be accounted for, supposing the story to be true.

In preparing a burning glass, the first thing to be considered is the figure necessary to collect all the rays into the smallest possible space. Descartes, in his *Optics*, showed that a disc of glass, convex on the one side and concave on the other, the convex side being a portion of an elliptic surface, and the concave a portion of a sphere, would cause parallel rays falling on its convex side to converge in a single point. But as the practical difficulties of forming a glass accurately into this shape are insuper-

able, both sides are ground into portions of a sphere. In a lens the focal length depends on the curvature, or the radius of the sphere, and on the refractive power of the substance of which the lens is formed.

The proper form for a burning mirror is the parabola; but as a parabolic curve is exceedingly difficult to obtain either upon metal or glass, opticians frequently rest content with a spherical curvature of long focus. Recently, burning mirrors have been constructed of glass, upon the curved surface of which pure silver is precipitated by chemical means. By this plan the curved surface is produced upon glass, and thus becomes permanent, whilst the reflection is effected by the polished surface of the silver which can be easily renewed from time to time. The focus of a burning mirror is one-half of the radius of curvature.

Among those who have experimented, modern times, upon the effects of burning glasses or mirrors, are reckoned Baron Napier, the illustrious inventor of the logarithms, Kircher Dr. James Gregory, Sir Isaac Newton, and many others. The most powerful solid lens ever constructed was the work of Mr. Parker, an ingenious London artist. It was made of flint glass, was 3 feet in diameter, $3\frac{1}{4}$ inches thick at the centre, its focal distance 6 feet 8 inches, the diameter of the burning focus 1 inch, and its weight 212 pounds. The rays refracted by this lens were received on a second, the diameter of which in the frame was 13 inches, and its focal length 29 inches. The diameter of the focus of the combined lenses was half an inch; consequently, by the addition of the second lens, the burning power was increased four times. With this lens some of the most refractory substances were fused in a very short space of time: for example, 10 grs. of common slate in 2 seconds; 10 grs. of cast iron in 3 seconds; 10 grs. of lava in 7 seconds; 10 grs. of jasper in 25 seconds, &c. This glass was afterwards carried to China by one of the officers who accompanied Lord Macartney, and left at Pekin. (For detailed information on this subject, the reader may consult the article 'Burning Glasses' in the *Encyclopædia Britannica*, 8th edition.)

Burnishing. In Gilding, this operation is performed with pieces of agate set in sticks, which, being rubbed over the surface of the gold-leaf, greatly increase its brilliancy. The parts which are intended to be in dead or *mat* gold are left unburnished.

Burr Stone or Burr Stone. A coarse cavernous stone, consisting almost entirely of silica, but full of cavities, and wearing in such a manner as always to expose a rough cutting surface. For this reason it makes an excellent mill stone. The best European burr stones are from France, the island of Sardinia, and Germany. The former are generally tertiary or oolitic; the latter of volcanic origin.

Bursæ Mucosæ. In Anatomy, synovial serous sacs, either subcutaneous or situated beneath tendons that glide over bones.

Bursars (Low Lat. *bursarius*, Fr. *boursier*, literally, *a pursuer*). In the English universities, this name is applied to the treasurers of colleges and halls.

In the Scottish and foreign universities it is applied to persons who are aided in their education by the grant of a small sum from a *bursæ* or fund set apart for that purpose. In the university of Edinburgh there are but few bursaries. George Heriot's Hospital (the most wealthy institution in Edinburgh) grants ten bursaries of 20*l.* per annum each, for four years, to persons not connected with the hospital, who, after a comparative trial before a committee of the governors of the institution, are found duly qualified. There are, besides, a few bursaries of 7*l.* and 10*l.* each given by the city of Edinburgh to students in the first year of their academical course; two of 10*l.* each to students named Stewart in the second year, and one of 100*l.* to a student selected from those called M'Pherson in the fourth year. To those may be added two ancient bursaries instituted for the benefit of Poles resident in Scotland, which, after lying dormant upwards of a century, were discovered and brought to light in 1837. At St. Andrews, there are several bursaries in the gift of the university; and at Aberdeen, besides the interest of 7,000*l.* devoted to the maintenance of certain students at that university, there are a few valuable exhibitions to Cambridge. At Glasgow the most important endowments of this kind are a few exhibitions to Oxford; and those left by Dr. Williamson for Englishmen not connected with the established church.

In Germany, where the system is largely carried out, the bursaries are called *Frei-tische*, or free-tables.

Burschenschaft (Ger.). A league or secret association of purschen, or students, formed in 1815, for the purpose, as was asserted, of the political regeneration of Germany, and suppressed, at least in name, by the exertions of the governments.

Burséracææ. A name formerly applied to a natural order of hypogynous Exogens, now more generally called *Amyridacææ*. It consists of trees and shrubs inhabiting the tropical parts of the world. They all are resinous and fragrant, having alternate unequally pinnate dotless leaves, and racemes or panicles of small green flowers. Their fruit is usually a drupe. Indian Frankincense, Myrrh, Olibanum, Colohane, the Balsams of Acouchi, Gilead, and Mecca, Gum Elemi, and other similar substances, are obtained from plants of this order; besides oil, pitch, and turpentine, resembling the vegetable secretions bearing those names in Europe.

Burster. The charge made up into a cartridge for bursting a shell.

Busby. The headdress worn by hussars, artillery and engineers in our army. It consists of a fur hat with a bag hanging from the top over the right side. This bag, which is made of the same colour as the facings of the regiment, appears to be a relic of a Hungarian

BUSHEL

ead-dress, from which a long padded bag hung over and was attached to the right shoulder as a defence against sword-cuts.

Bushel. An English measure of capacity, containing 8 gallons. By Act of Parliament, 6 Geo. IV. c. 74, the Imperial gallon is declared the standard measure of capacity, and is directed to be made such as to contain 10 lbs. avoirdupois of distilled water, weighed in air at the temperature of 62° of Fahrenheit's thermometer, the barometer standing at 30 inches; or to contain 277 cubic inches and 274 thousandth parts of a cubic inch. Consequently the Imperial bushel contains 80 lbs. of distilled water, or 2,218.192 cubic inches.

The *heaped* bushel of 2,816 cubic inches, declared by the same Act as a measure for coals, lime, potatoes, fruit and fish, was abolished in 1835 by Acts of Parliament 4 and 5 Wm. IV. c. 49. The Winchester bushel, in use from the time of Henry VII. to 1826, contained 2,150.42 cubic inches. The original standard Winchester bushel and yard measure are still preserved in the museum at Winchester.

[WEIGHTS AND MEASURES.]

Bushman (Dutch, *Boesjesmannen*, *men of the wood*). A name given by the Dutch colonists to some roaming tribes akin to the Hotentots, in the vicinity of the Cape of Good Hope. The description given by Governor Janssens of this people is very interesting. So deep are they sunk in barbarism as to be unacquainted even with the construction of huts or tents: 'the burning sky being their canopy, and the scorching sand their bed.' They are of a dark copper complexion, small in stature, and of a singularly malicious, wild, and intractable disposition.

Busiris. In Egyptian Mythology, a fabulous personage, of whose origin, exploits, and character the most contradictory accounts are given, some maintaining that he was a king of Egypt, others that the name signified only the tomb of Osiris. [OSIRIS.]

Buskin (probably bootikin, or *little boot*). A species of covering for the leg, or rather for the ankle and foot: generally used by English writers as a translation of *cothurnus*, *caliga*, and various other Greek and Latin words denoting different kinds of boots, &c. Hence *buskin*, in the sense of *cothurnus*, stands for the tragic drama, in contradistinction to *soccus*, the boot or sock worn by comedians, and used for the comic drama.

Great Fletcher never treads in *buskins* here,
Nor greater Jonson dares in *socks* appear.—DRYDEN.

Buss. A two-masted vessel used by the Dutch and English in the herring fishery. It is nearly obsolete now; but when employed is from fifty to seventy tons in burden.

Bustamite (named after the discoverer M. Bustamante). A grayish red variety of Rhodnite (or native silicate of manganese), occurring in irregularly disposed prismatic crystals, having at times a fibrous structure, at Real de Minas de Totala, in Mexico.

BUTTER-TREE

Bustard. [ORIS.]

Butcher Bird. [LANIUS.]

Butea (named after John, earl of Bute, a patron of botany). A genus of Indian *Leguminosæ*, consisting of trees and shrubs, which yield kino. *B. frondosa* (the *Dhak-tree*) affords a gorgeous spectacle when in flower, the masses of blossom resembling sheets of flame. It exudes from the bark of its trunk an astrigent juice, which when hardened forms one of the substances known as Kino.

Butic Acid. A solid matter contained in cow's butter in combination with glycerine.

Butomaceæ (*Butomus*, one of the genera). A natural order of endogenous aquatic plants, of the Alismal alliance. *Butomus umbellatus*, the Flowering Rush, is one of the most elegant of our native water plants.

Butt. A mound of earth used to receive the projectile at proof of and practice with firearms.

Butt Hinge. A hinge of cast or wrought iron, in which the flaps close like a book; it is usually let in flush with the head of a joint left for the purpose of concealing it. Projecting butts are those which are used when doors have to fold back, flat, against the side of the walls intended to receive them.

Butt Joint. The joint which is formed in Carpentry when two pieces of timber meet one another at right angles, and the fibres are parallel with the main axis of the abutting pieces.

Butter (Gr. *βούτυρον*, from *βοῦς*, and *τύπος*, *cheese* or *coagulum*). The oily part of milk: 100 parts of cream contain about 4.5 of butter and 3.5 curd; they are separated by the process of churning, during which the butter aggregates. Butter soon becomes sour and rancid, unless purified by melting and straining it so as to separate adhering curd; it is generally preserved by the addition of salt. Its *clain* or oily part has been called *butyrine*. When converted into soap, it is said, in addition to the usual products, to afford three odorous volatile compounds, which have been termed by Chevreul the *butyric*, *capric*, and *caproic acids*.

Butters, Mineral. A name given by the old chemists to some of the *chlorides* on account of their soft butyraceous texture when recently prepared; such as *butter of antimony*, of *tin*, and of *bismuth*.

Butters, Vegetable. The concrete fixed oils, such as those of the cocoa and chocolate nuts, of the nutmeg, &c., which are solid at common temperatures.

Butter-tree. A name given to certain remarkable trees of the genus *Bassia*, one of which, *Bassia Parkii*, the Shen-tree or Butter-tree of Africa, found by Park in the interior of Africa, yields from its kernels, by pressure, a white firm rich butter, which, even in that climate, will keep well for a year without salt. Another species is the *Phulwara* or Butter-tree of India (*Bassia butyracea*), whose seeds produce a firm agreeable buttery substance, of about the consistency and colour of hog's lard, used medicinally in rheumatic affections. The

BUTTERFLY

Illupie-tree of Coromandel (*Bassia longifolia*) and the Madhuca-tree of Bengal (*Bassia latifolia*) are other species having similar properties.

Butterfly. The common English name an extensive group of insects, as they appear in their last and fully developed state, when they constitute the most beautiful and elegant examples of their class. These insects belong to the order LEPIDOPTERA, and to the section DIURNA of Latreille, or the genus PAPILO of Linnaeus. [See those words.]

The changes of animal form produced by the progressive expansion of the enclosed organs of the body, and the successive shedding of the outer case or skin, are in no instances so striking or so extraordinary as in the present group of insects. These changes or metamorphoses, as they are commonly but incorrectly termed, have been a favourite theme to the divine and the poet, and a most attractive subject of research to the naturalist. The transition of the humble grub to the gorgeous image is the subject of the following beautiful passage in the classical work (the *Introduction to Entomology*) of Kirby and Spence: 'Were a naturalist to announce to the world the discovery of an animal which for the first two years of its life existed in the form of a serpent; which then, penetrating into the earth, and weaving a shroud of pure silk of the finest texture, contracted itself within this covering into a body without external mouth or limbs, and resembling more than anything else an Egyptian mummy; and which, lastly, after remaining in this state, without food and without motion, for three years longer, should at the end of that period burst its silken cerements, struggle through its earthly covering, and start into day a winged bird—what, think you, would be the sensation excited by this piece of intelligence?' The subterranean locality of the insect in its passive state, and the silken shroud, are, indeed, less applicable to the butterflies than to other insects; but the circumstances attending the transformations of these beautiful objects are not less remarkable than those of the beetles and moths.

The eggs of the butterfly are deposited on such plants as afford the nutriment most appropriate to the caterpillars that are to be excluded from them; thus the common white butterfly (*Pieris brassicae*, Latr.) and other species oviposit upon cabbages, and hence have been termed *Brassicariae*: the gaudy peacock-butterfly lays her eggs upon the nettle. The eggs are coated with a glutinous secretion as they are excluded from the parent, and thus provided with the means of adhesion to the leaves or stems of the plants selected.

The larvæ are long and cylindrical, and consist of thirteen segments, including the head; they have eight feet, and nine spiracles on each side. Those feet which are attached in pairs to the first three segments of the trunk enclose the parts which are developed into the permanent legs of the future butterfly; the re-

BUTYRIC ACID

maining five pairs of feet are membranous, short and thick, and are finally lost with the moultings of the skin, whence they are called 'pro-legs' by Kirby. The sides of the head are studded with twelve simple globular eyes, extremely minute, and very unlike the single large compound eye of the perfect insect. The mouth is provided with an apparatus characteristic of the mandibulate class of insects, having a pair of large and strong horny jaws working in a horizontal plane, and representing the 'mandibulæ'; beneath these a pair of smaller and softer jaws or 'maxillæ,' and a fleshy lower lip or 'labrum' united to the latter, and which is perforated by the outlets of the ducts of the complicated apparatus for secreting the silk. Such a condition of the 'instrumenta cibaria' or mechanism of the mouth is in perfect harmony with the habits of the caterpillar, and with the part assigned to this larva or masked Lepidopterous insect in the great theatre of nature. It is there destined to crop and devour the solid succulent parts of the otherwise too luxuriant vegetation, and must have jaws and teeth to perform its task. In its subsequent and final character the butterfly uxuriates on the exquisitely elaborated juices of the flower, and has the power to raise itself above the dull earth, and to transport itself through the air.

Button. The round mass of metal collected at the bottom of a crucible after fusion, or which remains in the cupel in the process of assaying, is called by this name.

Buttress. In Architecture, a mass of masonry, or brickwork, built to resist the horizontal thrust of another mass; though when they are on the opposite side to the thrust and below the line of its effort, they are frequently called *counterforts*. Buttresses are much used in Gothic architecture to counterbalance the outward thrust of the arches, or of the vaulting which covers the naves and aisles of cathedrals. When they are open, and carry down the thrust to a point of support at some distance from the spot where it is exercised, they are called flying buttresses.

Butts. Short ridges of different lengths, which necessarily occur in the angle of a field when the direction of the ridges is not parallel to one of the sides.

Butyl, Balyl or Tetryl. The radical or basis of a number of chemical compounds, of which butylic alcohol is perhaps the most important. The latter body is formed during the fermentation of beetroot molasses; a number of derivatives may be obtained from it resembling, more or less, those prepared from ordinary vinic alcohol.

Butyric Acid. One of the fatty acids contained in butter: it is also formed in certain cases in which sugar undergoes fermentation in contact with curd, and hence termed *butyric fermentation*. This acid is a volatile colourless, and very mobile liquid, of a pungent sour-lour, resembling that of a mixture of acetic acid and rancid butter, its taste is first pungent

BUTYRINE

and sour, then sweetish and ethereal. The chemical formula of this acid is $C_4H_7O_2 + HO$; that is, the anhydrous butyric acid consists of 8 atoms of carbon, 7 of hydrogen, and 3 of oxygen; which in the ordinary acid are combined with an atom of water: in the *butyrates* this atom of water is replaced by an atom of base.

Butyrine. A solid fat composed of butyric acid and glycerine. It occurs in butter.

Butyrene. An interesting chemical substance occurring among the products of the distillation of butyrate of lime. It is homologous with acetone and propene.

Buxine. A bitter alkaloid contained in the tissues of the box-tree.

Buzzard. [FALCO.]

By-laws or Bye-laws (the first syllable from the Danish *By, town or hamlet*). Orders and constitutions of corporations, courts-leet and courts-baron, commoners, or inhabitants of villis, &c., of which the effect is to impose obligations not enforced by common or statute law. The validity of by-laws rests on the authority of the parties making them, established either by immemorial custom, or by their corporate character; for the power of making by-laws is inherent in a corporation. But the superior courts of law have the power of annulling a by-law, if it be unreasonable, or in restraint of trade, or imposing a charge without any apparent benefit to the party, &c. By the Municipal Corporations Amendment Act (5 & 6 Wm. IV. c. 78, s. 90) by-laws are to be made by the town council of the borough, and to be valid unless disallowed by the king in council within forty days.

Byard. A piece of leather crossing the breast, used by the men who drag the sledges in coal mines.

Byrrhus. A Linnæan genus of minute Clavicorn Coleopterous insects, now the type of a family, including those pests of museums which feed in the larva state on bird-skins, preserved insects, &c. The genera in this family are *Byrrhus* proper; *Simplocaria*, *Oomorphus*, *Syncoalypta*, *Nosodendron*, *Aspidiphorus*, *Trinodes*, and *Anthrenus*. Of the latter genus there are six British species, of which the *Anthrenus muscorum* may be regarded as the type.

Byssifera, Byssifera (Lat. byssus, and fero, I carry). A family of Lamellibranchiate Acephalous Mollusca, comprehending those species which are attached to foreign bodies by means of a byssus.

Byssolite (Gr. *βύσσος, flax*, and *λίθος, stone*). A blue variety of Actinolite. It occurs in cavities of crystalline rocks in several parts of the Alps.

Byssus (Lat.; Gr. *βύσσος*). A fasciculus of shining semitransparent horny or silky filaments, secreted by a gland at the base of the foot in certain Lamellibranchiate Bivalves, and serving as an organ of adhesion to submarine rocks or other foreign bodies.

Byssus. A name formerly given to all those filamentous plants which inhabit cellars and other underground close places, and on which

BYZANTINE HISTORIANS

no fructification is found; it was also applied to vegetation of a similar kind when found growing in the air. It is now ascertained that a large number of these supposed plants are merely the young state of certain kinds of fungi, or other plants of a low organisation; and the genus is consequently exploded, the term *Byssoid* alone being retained to express a fringed structure in which the threads are of unequal lengths.

Bytownite. A mineral which is probably a mixture of different felspars. It is found in large boulders near Ottawa (formerly called Bytown), in Canada West.

Byttneriaceæ (Byttneria, one of the genera). A natural order of Hypogynous Exogens, allied to the *Sterculiaceæ*, consisting of trees and shrubs, chiefly tropical or sub-tropical, with simple leaves, and monadelphous stamens. The order contains *Theobroma Cacao*, from the seeds of which chocolate and cocoa are prepared. The fibrous bark of many species is adapted for the manufacture of cordage.

Byzantine Art. In Ornament and Architecture, is that symbolic system which was developed by the early Greek artists out of the Christian symbolism. The great features are the circle and dome, the round arch, and all the various details of form which are derived from the lily, the cross, the vesica, the nimbus and other symbols. The great examples of this style are St. Sophia at Constantinople, and St. Mark at Venice. (Salzenberg's *Allchristliche Baudenkmale von Constantinopel*, &c. folio, Berlin 1854; Kreutz, *La Basilica di San Marco*, &c. folio, Venice 1843; and Ruskin's *Stones of Venice*, 1861-3.)

Byzantine Historians. A series of Greek historical authors, who lived under the Eastern Empire between the sixth and the fifteenth centuries. They may be divided into three classes: 1. Historians whose works form a continuous history of the Byzantine Empire from the fourth century of the Christian era down to the Turkish conquest of Constantinople. They are nearly thirty in number, with various shades of literary merit; but their works constitute almost the only authentic source of the history of that eventful period. 2. General chroniclers or historians, whose works treat chiefly of the chronography of the world from the oldest times. 3. Authors who confined their attention to the politics, statistics, antiquities, manners &c. of the Romans. These two latter classes combined amount also to about thirty, and their writings give an excellent illustration of the times of which they treat. The works of the Byzantine historians &c. were collected and published by order of Louis XIV. in 36 vols. folio, Paris 1645-1711. Another edition was published at Venice in 1729 and the following years. A more complete edition was projected by Niebuhr, the historian of Rome (*Corpus Scriptorum Historiæ Byzantinæ*, editio emendatior et copiosior, 8vo. Bonnæ 1828). This edition was superintended by him till his death; and it has since that time been carried on by Becker, Dindorf, and other eminent philologists.

C

C. The third letter of the English and most other European alphabets. It is borrowed immediately from the Latin alphabet, in which it first appears; but is derived originally from the κ or γ of the Greeks. In English it is pronounced like *s* before *e* and *i*, and like *k* before *a*, *o*, *u*, and may consequently be considered as superfluous in the alphabet. As an abbreviation, C is used in ancient MSS. for Caius, Cæsar, Consul, Civitas, &c.; and as a numeral for a hundred. It was the symbol of condemnation in the Roman tribunals (being abbreviated for *Condemno*); and was consequently termed *littera tristis*, in contradistinction to A (used for *Absolvo*), symbolical of acquittal, and thence called *littera salutaris*.

C. In Music, the name of one of the notes in the scale, corresponding to the *Ut* of the French, or the *Do* of the Italians. It is a character also used for the signification of Common Time. [Music.]

Ca ira (Fr. *It [the Revolution] shall go on*). The burden of a famous revolutionary song, which was composed in the year 1790 in denunciation of the French aristocracy. The object of the equally well known Marseillaise hymn ('*Allons, enfants de la patrie*') was to rouse the French to defend their country against foreign aggression.

Caaba. The name of the great temple at Mecca, given to it from the black stone which was worshipped there before the time of Mahomet (or Mohammed) and which is still an object of veneration to all Mahometans. According to the tradition of the Arabs, this stone was presented by the angel Gabriel to the patriarch Abraham on the occasion of the building of the temple; but the nature of the Caaba worship proves that there is nothing Abrahamic in the superstition. The temple had become ruinous, and was rebuilt while Mahomet lived at Mecca; and it is said that he himself guided the stone to its place in the north-east corner of the Caaba. This great object of Mahometan pilgrimage appears to be a large ærolite, and the veneration for it arose in the original Fetish worship of stones. (Muir's *Life of Mahomet*, vol. i. p. 210 &c. and ii. 34 &c.)

Cabal (Fr. *cabale*). In English History, was applied originally to the five cabinet ministers of Charles II.—Clifford, Ashley, Buckingham, Arlington, and Lauderdale—whose initials happened to form the word; and it has since been used for any junto of men who, too insignificant in point of numbers to form a party, endeavour to effect their purposes by underhand measures.

Cabala. A Hebrew word, signifying the body of generally received tradition by which the Rabbins interpreted the canonical Scriptures. According to their belief, the unwritten tradition, or *Masora*, had been handed

down in regular succession from Moses, who received it on Mount Sinai. To this tradition frequent reference is made in the teaching of Christ, as in the Sermon on the Mount, &c.; and on it the Pharisees rested their claim to authority as interpreters of Scripture. As the *Masora* gives the literal explanation of the language of Scripture, so the *Cabala* reveals the hidden truths of which it is the symbol. Every sentence, word, and letter of the inspired volume contains, according to these interpreters, a figurative as well as a direct sense. The former is also not uncommonly manifold; and a word may be interpreted according to the arithmetical power of the letters which compose it, which species of cabala is called *gematria*; or according to the meaning of each individual letter, the entire word thus constituting a sentence, which is called *notaricon*; or finally according to certain transpositions of the letters, which is denoted by the term *themurah*. The system seems to have been an invention of the philosophising Jews of the latter centuries preceding our era, with the view of accommodating the speculations of the Gnostics to the religion of the Old Testament. (Milman's *Hist. of Christianity*, vol. i. ch. i.; *Hist. of the Jews*, book xix.; Ginsburg, *The Kabbalah*.)

The Christian cabalists in later times practised a kind of magic under this name, pretending to the power of divination by certain combinations of scriptural characters.

Cabiál. In Zoology, the name under which the Capybara or water-hog (*Hydrochærus Capybara*, Erxl.) is described by Buffon. [CAPYBARA.]

Cabin (Fr. *cabane*). A rough kind of enclosure for the purpose of protecting any one from the weather, such as shepherds erect in country districts. The origin of architecture is traced to these structures by the fanciful theorists who have written on the subject. Mazois gives in his work upon the ruins of Pompeii a representation of the early Italian cabins.

CABIN. On Shipboard, is a chamber of greater or less size, separated by light panelling from the rest of the deck. It serves as the apartment of some officer or passenger; or it may be a saloon for the use of many. In ships of war the partitions are readily removed when it is necessary to clear the decks for action.

Cabinet (Fr.). In Politics, the governing council of a country: so called from the cabinet or apartment in which the ruler transacts public business and assembles his privy council. In England a few of the ministers only are by official usage members of the cabinet. These are styled Cabinet ministers, and are more immediately responsible for the acts of the sovereign, as well as for public measures: but

CABIRI

notwithstanding the high importance of their position, they have no recognised legal character. The distinction between the king's cabinet ministers and the rest of his privy council seems not to have been established in public usage in England before the reign of William III.

Cabiri (Gr. *καβίροι*). Certain mystic deities, worshipped in Greece, Egypt, &c., and specially in Lemnos, Samothrace and Imbros. The vague and contradictory accounts given of them by various writers render it impossible to arrive at any certain conclusions as to their real character, and the nature of their worship, which was made a matter of the greatest mystery. By some they have been regarded as exclusively Pelasgic divinities; by others they have been identified with the Roman Penates and the Dioseuri. To account for their name, they were said to be children of Hephæstus (or Vulcan) and Cabeira the daughter of Proteus. They are mentioned by Herodotus (ii. 51, iii. 37); but his statements are not more definite than those of later writers. The subject is examined at length in Lobeck's *Aglaophamus*.

Cable (Fr. *câble*; Span. *cabra*, cable; Port. *calabra*, *cabre*). The rope or chain by which the anchor of a ship is held. Cables in Europe, until within a recent period, were usually made of hemp, but of late years iron chains have come much into use. A hempen cable of 12 inches girth, and length 120 fathoms, weighs 3,075 lbs. Since the weights of two cables of equal lengths will be as their sections, or squares of the girths, it is easy to deduce the following rule for the weight of any hempen cable: Multiply the square of the girth in inches by 21·3 (or 21 nearly enough); the product is the weight, in lbs. Since also as the breaking strain, or resistance against the force to part the cable, will be as the section, it will be as the weight, and will be found nearly by dividing the weight in lbs. by 100; the quotient is the breaking strain in tons. This rule is of course liable to great uncertainty from the quality or wear of the cable. Chain cables possess great advantages over hempen cables; they are not liable to be destroyed by chafing on rocky grounds, nor to become rotten and insecure from alternate exposure to the air and water; and by reason of their greater weight the strain is exerted on the cable rather than on the ship. In order that the ship may be enabled to let slip her cable in case of necessity, chain cables are furnished with bolts at distances from each other of a fathom or two, which can be readily withdrawn. A chain of which the section is 1 inch in diameter breaks with 16 tons; such a chain is equivalent to a 10-inch hempen cable nearly. And the dimensions of the chain cable corresponding to any hempen cable are therefore easily found by merely dividing the circumference of the hempen cable by 10. The strength of every part of the chain is proved before it leaves the manufactory, nor may any chain be used on shipboard until it has been tested and certified by an officer appointed by the Board

CACHOLONG

of Ordnance. The penalty for supplying a cable not so tested is 50*l*. The first patent for a chain cable was taken out in 1808 by Mr. Slater, a surgeon in the Royal Navy.

Cable. In Architecture, the term cable is applied to a moulding that is ornamented in such a way as to resemble a cable; it is frequently applied to the lower part of a column, which is filled in with a decoration of this kind inserted in the flutes.

Cabled. In Architecture, the filling up the lower part of the flute of a column with a cylindrical piece like a cable.

Cabocle. The Brazilian name for a compact brick-red mineral, resembling red Jasper, which is found in the diamond-sand of the province of Bahia. It contains phosphoric acid, alumina, lime, baryta, protoxide of iron, and water.

Cabombacæ (Cabomba, one of the genera). A small order of Exogens belonging to the Nymphal alliance. The plants are aquatics, with floating shield-like leaves and three to four petaled flowers, and are found both in North and South America, as well as in New Holland. The distinguishing peculiarities of the group are their distinct carpels, the abundant albumen in the seeds, and the absence of a torus. The order has sometimes been called *Hydropeltideæ*, and bears the popular name of Watershields. The submersed leaves are capillary.

Cachalot. In Ichthyology, a name for the spermaceti or sperm whale (*Physeter macrocephalus*, Linn.).

Cachet, Lettres de (Fr.). In France, under the ancient government, letters signed with the private seal (cachet) of the king. As warrants for the detention of private citizens, they appear to have been rarely employed before the seventeenth century. In the reign of Louis XIV. their use became frightfully common. But in other respects they had been not unfrequently made use of, even in earlier times, to interfere with the course of justice; as, by way of injunction to a party not to exercise certain authority or pursue certain legal steps, &c. Lettres de cachet were never so multiplied as under the administration of Cardinal Fleury: not less than 80,000 are said to have been issued, without any legal judgment, in the proceedings against the Jansenists. Fifty-nine are said to have been issued against the family Mirabeau in the reigns of Louis XV. and Louis XVI., of which twenty-two were against the famous count himself. They were abolished Jan. 15, 1790.

Cachexia (Gr. *καχεξία*, from *κακός*, bad, and *ἔξις*, a habit). A bad state or habit of body; whence the term *cachexie*, or cachectic disorders.

Cacholong. A milk-white variety of Opal, allied to Hydrophane. It is found in Ireland, in the trap rocks of Iceland, in Greenland and the Faroe Islands. It was originally discovered on the banks of the river *Cach* in Bucharia, where it occurs in large loose masses: hence the origin of the name; the word *Cholong*, in the

CACHUNDE

language of the Calmucks, being said to signify a stone.

Cachunde. A celebrated Chinese medicine, composed chiefly of aromatic stimulants.

Cacodemon (Gr. *κακοδαίμων*, an evil spirit). [DÆMON.]

Cacodyle. [ΚΑΚΟΔΥΛΗ.]

Cacophony (Gr. *κακοφωνία*, from *κακός*, bad, and *φωνή*, a sound). In Rhetoric, a harsh or disagreeable sound produced by the meeting of two or more letters or syllables, or by the too frequent repetition of the same letters or syllables: e.g.

And oft the ear the open vowels tire.—POPE.

Cacotheline. A feeble alkaloid derived from brucine by the action of nitric acid.

Cacoxene. [ΚΑΚΟΧΗΝΗ.]

Cactaceæ (Cactus, the old name of one of the genera). A small natural order of Exogens, remarkable for their gay and large flowers, and for the grotesque forms of some of the species, which are nearly all succulent. They are found wild in hot dry countries, in arid situations, where they are enabled to exist because of the thickness of their skin, which allows very little moisture to be lost through it. The principal features are the numerous undistinguishable sepals and petals, the scattered stamens, the confluent styles, and the exalbuminous seeds. Many of the species are like succulent Euphorbias, from which they are, however, known by their not giving a milky sap when wounded. All the species are harmless. Some have eatable fruit, as *Opuntia vulgaris*, the Prickly Pear; and one of them, the Nopal, *Opuntia cochinitifera*, is the favourite haunt of the cochineal insect.

Cacus. In Latin Mythology, the son of Vulcan, a robber of Italy, whose dwelling was in the Aventine wood. His exploits form the subject of an episode in the eighth book of the *Æneid*. He was represented as a frightful monster of enormous strength, who, after a long life of crime, was at length slain by Hercules, from whom he had stolen some oxen. To express his gratitude for his victory, Hercules erected the *Ara Maxima*; and Evander, with his infant colony of Arcadians, paid divine honours to Hercules as their benefactor. For the origin, history, and meaning of the myth, see Breal, *Hercule et Cacus* (Paris, A. Durand, 1863).

Cadastral Survey (Fr. *cadastre*, from *cadrer*, to square with). A term of late years generally adopted on the Continent, and now used in England, to denote a survey on a large scale. A cadastral as opposed to a topographical map may be defined to be one on which the objects represented agree, as to their relative positions and dimensions, with the objects on the face of the country; while a topographical map, usually drawn on a small scale, exaggerates the dimensions of houses and the breadth of roads and streams, for the sake of distinctness, and is, owing to its smaller size, necessarily less correct than a

CADENCE

cadastral plan. The scale on which the national survey of the United Kingdom is in future to be drawn, is that which has been generally adopted throughout Europe, namely '0004, or $\frac{1}{2500}$ of the linear measure of the ground. This scale corresponds so nearly to twenty-five inches to one mile, that it is usually spoken of as the twenty-five inch scale. (*Edinburgh Review*, vol. cxviii. p. 378.)

Caddice-worms or Case-worms. The larvæ or grubs of the Trichopterous insects are so called, on account of being enclosed in a sheath or case. This is always composed of extraneous substances glued together by a cement excreted from the skin of the grub; and different species of the caddice-worm protect themselves by means of different materials thus joined together. Some, which pass their larva state under water and creep along the bottom, combine bits of sticks or rushes with small pebbles or shells, to make their cases heavier than water; others, which float on the top and there gather their food, form a slight and slender tube of a narrow slip of grass, which is rolled round the body in a spiral direction, with the edges so nicely fitting as to seem but one piece. In every case the worm adheres by a pair of hooks at its hinder extremity to the bottom of the sheath, and only protrudes the head and two following segments, the skin of which is harder than that covering the rest of the body. Those which creep at the bottom drag themselves along by means of their mandibles. At the conclusion of their existence as grubs, they moor their case to some large stone or other fixed and submerged body, and close the outlet by a network of silken threads, which prevents the entry of any unfriendly intruder, but admits the water necessary for respiration. They then cast their outer skin, and for a while remain in the usual passive condition of a pupa; while the organising energy is vigorously effecting the wonderful changes which lead to the full perfection of the insect. But, as it would be obviously dangerous to the air-breathing imago to be excluded in its first feeble state under water, the pupa here exhibits a locomotive power which is without a parallel in other orders of the metamorphic insects: being provided with a pair of small and sharp hooks at the head, it cuts the threads with which in a previous state it had confined itself, and creeping out of the water casts off its pupa skin, and emerges a May-fly or *Phryganea*.

Cadence (Ital. *cadenza*, a falling). In Music, the conclusion of a song, or of some parts thereof, in certain places of the piece, dividing it as it were into so many numbers or periods. The cadence takes place when the parts fall or terminate on a note or chord naturally expected by the ear, just as a period closes the sense in the paragraph of a discourse. A cadence is either perfect or imperfect. The former when it consists of two notes sung after each other, or by degrees conjoined in each of the two parts, the harmony of the fifth

CADENZA

preceding that of the key-note; and it is called perfect, because it satisfies the ear more than the latter. The latter imperfect; that is, when the key-note with its harmony precedes that of the fifth without its added seventh. A cadence is said to be broken or interrupted when the bass rises a major or minor second, instead of falling a fifth.

Cadenza (Ital.). This term, although etymologically the same as cadence, is used to denote a passage in a concerto, introduced at the pleasure of the player, to exhibit his skill of performance or composition, immediately before the end of a movement.

Cadet. This word, meaning in French a younger member of a family, implies in English a student at either the Royal Military Academy at Woolwich, or the Royal Military College at Sandhurst. The cadets at these establishments, though neither commissioned as officers nor enlisted as soldiers, receive pay, wear uniform, and are subject to military discipline. In order to gain a commission in the Royal Artillery or Engineers, it is necessary to pass through the former of these establishments, and through the latter in order to obtain a commission without purchase in the Line. These cadetships are open to any British subject, within certain limits of age, who can produce certificates of good moral character, who is not physically disqualified, and who succeeds in the competition.

A much higher standard of qualification is required for admission to Woolwich than to Sandhurst, good mathematical attainments being indispensable; and as the number of candidates always far exceeds that of vacancies, the competition is very severe. The shortest time in which a cadet can pass through Woolwich is two and a half years; and the course of instruction, in addition to drill, gymnastics and riding, comprises the following subjects: mathematics, practical geometry, French, German, Hindustani, plan-drawing and surveying, mechanics, chemistry, experimental sciences, natural philosophy, geology and mineralogy, fortification and artillery. On passing their final examination at the Academy, the cadets state whether they wish to enter the Artillery or Engineers, and the highest are commissioned in whichever they prefer. The course of instruction up to the hour of leaving is the same for both services.

For Sandhurst, the entrance examination is easier: the course of study is of less duration, and comprises much the same subjects. The cadets who gain the highest places at the final examination get commissions without purchase; the remainder are allowed to purchase commissions as vacancies occur.

The field-marshal commanding-in-chief is governor of the Royal Military Academy at Woolwich, and under him is a general officer as lieutenant-governor. The government of Sandhurst is vested in commissioners, of whom the commander-in-chief is president: and a general officer is governor of the college. While the son of a private gentleman pays

CADUCEUS

125*l.* per annum for education at either of these establishments, the sons of officers pay less according to a sliding scale, the sons of lieutenants paying only 40*l.* per annum.

The chief military schools in France are the polytechnic school at Paris for the Artillery and Engineer cadets, and the military school at St. Cyr near Versailles for the Line; officers, however, in the proportion of one-third of the whole are obtained from the ranks of the army.

In Prussia there are four cadet schools in the provinces, and one upper cadet school at Berlin. After joining the army, every officer goes through a course of instruction before finally obtaining a commission.

In Austria the officer's education begins at an early age. The chief military school is at Wiener Neustadt near Vienna.

The Italian system is like the French, and the military school is at Turin.

The West Point Academy, in the United States, has educated some of the best officers who have been employed in the present American war.

In Russia there is a famous academy for cadets, which was instituted by the Empress Anna at St. Petersburg in 1732.

Cadet, Naval. Holds a sort of preparatory appointment in the British Navy. Young gentlemen are eligible for the rank from twelve to fourteen years of age. The nominations rest with the Admiralty, except that every captain on commissioning a ship has one, and every admiral on hoisting his flag has two. Candidates pass a preliminary examination, and are then draughted into a training ship, for a few months, for instruction in rigging and other technical matters. After eighteen months' service, a cadet becomes eligible for the rank of midshipman. Naval cadets of the second class, after their term of service, become master's assistants instead of midshipmen.

Cadet's Fuming Liqueur. [ALCAORSIN.]

Cadi (Arab. *a judge*). Among the Turks the inferior judges are styled Cadi. The Spanish Alcayde or Alcalde is derived from the same root. Cadi Lesker signifies a higher order of judge.

Cadmium. A white metal, much like tin: it fuses and volatilises at a temperature a little below that at which tin melts. Specific gravity about 9. Its ores are associated with those of zinc. It was discovered in 1818 by Prof. Stromeyer of Göttingen. Its equivalent number is 56. It forms a yellow salifiable oxide composed of 56 cadmium + 8 oxygen = 64 oxide of cadmium. Its scarcity prevents its employment in the arts, but the oxide is used as a pigment.

Cadmus. [EUROPA; TELEPHASA.]

Caduceus (Lat.). In Antiquity, a rod of laurel or olive with a representation of two snakes twisted round it. It was the symbol of peace, and formed the chief badge of heralds, whose persons were held sacred. In Mythology, the Caduceus was the symbol of Mercury, thence called Caducifer, to whom it was said to

have been presented by Apollo in return for his invention of the lyre.

Caducibranchiatus (Lat. *caducus*, *falling*; *branchiæ*, *gills*). Those Batrachians which undergo a metamorphosis, and lose their branchial apparatus before arriving at the period of maturity; as the frog, toad, salamander, and newt.

Caducous (Lat. *caducus*). In Botany, when a part is temporary and soon disappears or falls off.

Cæca (Lat. *cæcus*, *blind*). In Comparative Anatomy, the blind processes of the alimentary canal are generally so called. Those in fishes occur at the beginning of the intestines, where they are often numerous and long, representing the pancreas. In birds they are found near the termination of the intestines, and are generally two in number. In mammals the cæcum is commonly single, and situated at the beginning of the large intestines; it is of enormous size in the herbivorous species with simple stomachs. In the lower animals the intestinal glands which communicate with the intestines generally retain their primitive form of cæca.

Cæcum (Lat. *cæcus*). In Human Anatomy, the first portion of the large intestine, in which the *ileum* terminates by a valve. The cæcum is a kind of appendage to the intestinal canal, open at one end only, whence the name *blind gut*; it has a small process attached to it, called the *appendix cæci vermiformis*.

Cænozoic or **Kainozoic** (Gr. *kainos*, *new*, and *zōs*, *living*). A name introduced in modern Geology to include the whole group of Tertiary rocks. It corresponds with **Palæozoic** and **Mesozoic** [which see]. The more usual designations of Secondary and Tertiary must, however, for the present retain their place in geological works, although **Palæozoic** has entirely superseded Primary. [TERTIARY.]

Cæsalpinia (after Andreas Cæsalpinus, physician to Pope Clement VIII.). A genus of *Leguminosæ*, consisting of tropical trees or shrubs, and belonging to that division of the order in which the petals are imbricated, and the uppermost interior, not exterior, as they are in the papilionaceous division. *C. coriaria*, sometimes called *Lahidibia coriaria*, produces the pods known in commerce as *Divi-divi* or *Libi-dibi*, used for tanning purposes. Brazil-wood and Nicaragua-wood, so important to dyers, are produced by other species, as *C. crista* and *echinata*; and *C. Sappan* furnishes the red dye wood called Sappan-wood. These trees have compound leaves, and their flowers have five unequal stalked petals, and ten stamens.

Cæsar. This title, originally the name of a branch of the Julian family at Rome, was assumed as a mark of dignity by the emperors after Nero. It became subsequently the title of the presumptive heir to the empire, and the next title of dignity after Augustus; but was superseded in the Greek empire under Alexie Comnenus by that of Sebastocrator. In the West, it was conferred on Charles the Great,
